Turntables. The longer turntables result in a more economical use of floor space in the enginehouse. In other words, about 54 stalls can be obtained with a 100-ft. table and 72 stalls with a 125-ft. table. Larger tables permit more track approaches to the table without frogs and result in a smaller angle of spread in the sides of the stalls. Some engineers have figured that the saving in floor space in the enginehouse resulting from the use of a 125-ft. table over that of a 100-ft. table would pay for the increased cost of the longer table. A new development in turntable construction which permits the handling of large Mallets on short tables is the 3-point bearing table. This is now in use on the Pennsylvania Lines and is being considered by a number of other roads.

Inspection Pits. General opinion seems to agree with the author that the inspection pits are essential to modern terminal operation and that the inspectors should be protected from the weather. An office should be provided at this point where the crews, as well as inspectors, can make out their reports. This office should be connected to the roundhouse by a pneumatic-tube system for the transmission of reports. As a matter of interest, it has been found that more satisfactory results can be obtained from these tubes if they are installed overhead rather than underground.

Recently several have suggested that certain light repairs be undertaken at the inspection pit. Inasmuch as the time required at the ashpit largely controls the movement of power to the roundhouse, in many instances it would be possible to undertake light repairs at the inspection pit. This would consume most of the time which in many terminals is wasted by locomotives waiting for their turn at the ashpits.

Wash Pits. Another development which has been adopted by several roads is the installation of a wash pit for cleaning locomotives by oil, water and air spray. This method, it is said, gives better results than attempting to do the work in the roundhouse and is much cheaper.

Heating and Ventilation. Recently the writer heard a discussion of this subject as it relates to enginehouses and concluded that in some instances, at least, the motive-power departments were opposed to the hot-blast heating system.

The satisfactory results obtained by many roads recommend this system above any other for roundhouses, because it does assist in ventilation, which is essential for good results in the roundhouse. The blast may be controlled by dampers at the outlets and it has the advantage of being serviceable all the year round. In the summer months outside air may be forced through the system for ventilating purposes only.

The author refers to the smoke-exhaust system as being used for the purpose of meeting the objection to smoke on the part of the public. There is real economy in the smoke-exhaust system, in that it saves the live steam used in the blower lines and at the same time makes possible a reduction in the amount of fuel required to get good heat in the house during the winter months.

Oil House. The author specifically recommends that the oil

house be in a separate building. In a recent discussion of this subject by railroad-building engineers, it was agreed that for small terminals better results could be obtained by making the oil house a part of the storehouse so that it could be handled by the storekeeper.

Storehouse. The storehouse is a terminal facility that usually does not receive the attention that it should. Generally, very few labor-saving devices are provided for unloading or transporting supplies and there are instances where very substantial savings could be made if these matters were seriously considered.

T. N. Gilmore[1] In considering the extent of the shop facilities to be provided, it seems necessary to classify engine terminals into three classes, of equal importance.

The first we may designate as the divisional terminal, more remotely located from the main shop and where in connection with the roundhouse, which would be supplied with all the usual facilities, there would be a small erecting shop with its machine shop.

Second are main divisional roundhouses which would be responsible for maintenance of running repairs on all locomotives running out of them. Such a terminal would be supported more or less directly by a main shop, located adjacent thereto.

Third are the intermediate or engine-turning roundhouses where all locomotives entering the terminal run out of a main roundhouse at the opposite end of their runs, where running repairs are maintained.

In the first class, where a considerable number of engines are given light classified repairs between general overhaulings in the main shop, it seems desirable in point of time and cost to provide a separate shop equipped with unwheeling device and crane for handling the heavy parts of the locomotives, with a very complete outfit of machine tools, including those required for renewing and turning tires of drivers, truck and trailer wheels, heavy driving-box work and quite thorough repairs to the locomotive, with boiler-shop facilities for renewing flues, and a blacksmith shop.

A shop of this kind should be fully provided with standard trams, gages and templets in order properly to maintain established standards, and should be provided with a sufficient line of standard reamers and hand tools. The shop management should also be furnished detailed drawings of the locomotives in service.

The engine terminal supported more or less indirectly by a nearby main shop would require its own machine shop with machine tools sufficient to take care of the general heavy running repairs, depending upon the main shop or the storeroom for manufactured material such as crankpins, rods, crossheads, knuckle-joint pins, etc.

Of equal importance, however, is the full complement of mechanics' hand tools in sufficient number to avoid one workman's having to wait on another for a tool. In fact, the tool equipment should comprise all modern labor-saving appliances that will contribute to economy and speed of performance.

At the intermediate terminals where provision is made elsewhere for other than minor running repairs, the facilities, aside from the roundhouse, would consist of oil house, sub-store, suitable coal and cinder plants and water supply, including a sufficient dependable supply of steam for heating and other requirements, and also, where boilers are to be washed out, a hot-water boiler-washing system.

As before mentioned, the engines running into this class of terminal, at the opposite end of their runs, go into a roundhouse fully equipped to take care of running repairs.

It is relatively a simple matter on a comparatively short, compactly situated railroad system to decide on the location of each of these types of terminals. It becomes a very different matter, however, to locate and classify these terminals on the larger systems extending from New York to Chicago, St. Louis and Cincinnati and from Chicago to the Pacific Coast and St. Paul to the Coast and on systems where there are many branch lines.

In support of this general classification of engine terminals, the writer holds that every locomotive in service should have a home and an organization responsible for obtaining the proper average mileage between heavy general repairs.

[1] Vice-President, Dwight P. Robinson Company, New York. Mem.Am. Soc.M.E.

In the recent discussion on electric and steam locomotives the point was brought out that the electric locomotive could not be successfully operated under certain overload conditions, where the steam locomotive, if overloaded, would manage to get along somehow in a more or less indifferent manner.

It is a lamentable fact that the steam locomotive too often is continued in service in such condition that it may be said to be getting along somehow, resulting in poor transportation results and bad fuel economy.

The engine terminals of a railroad cannot be expected to maintain heavy power in good condition without the support of modern general repair shops to regularly and periodically put the engines into 100 per cent condition.

No locomotive terminal can be made modern without giving it an up-to-date organization. There should be no division of authority.

The proper spirit of coöperation should be built up and maintained between the different departments to enable this to be successfully carried out without friction and to the benefit of all departments.

L. G. Plant.[1] The locomotive terminal is a unique mechanical facility in that it admits of very little standardization. There are, however, certain well-defined principles relating to terminal layout that should govern in modernizing locomotive terminals. It is safe to say that where trackage is ample, a well-defined routine for the movement of every locomotive can be strictly adhered to.

With respect to coal chutes and sanding facilities, it should be borne in mind that the particular type of construction and the particular mode of operation are of no significance unless they insure both capacity and reliability in operation. The cost of delivering coal to locomotives is an important item and the coal chute should also be designed so as to minimize this cost.

The arrangement of fire-cleaning facilities and ash-handling apparatus is easily the most vital feature exterior to the roundhouse. The importance of these facilities lies in the fact that whereas the time consumed in taking coal and sand can hardly be in excess of ten minutes, the time over the ashpit may easily take one or two hours unless these facilities are reasonably adequate. The superiority of the water pit at any point where a considerable number of locomotives are to be handled can hardly be questioned, but this should be so designed that the locomotive ashpan is accessible to fire cleaners working on either side of the locomotive. Moreover a short transverse pit serving several pits is always preferable to a long longitudinal pit serving but one or two tracks. The principles which have been referred to as governing the track layout at the terminal apply with equal force to the arrangement of the ashpit.

The author is to be commended for his emphasis on the advantages of suitable inspection pits over which the locomotives pass before having their fires drawn.

Those sections of the paper dealing with heating, ventilation and lighting elaborate upon details that are very essential to the successful operation of any locomotive terminal. The author, however, has questioned the advisability of using the down-draft system of ventilation without putting sufficient emphasis upon the fact that this system as applied to roundhouses on the Pennsylvania Lines West has enabled the use of 75-ft. overhead cranes throughout the entire circumference of the roundhouse, which is in itself a most important labor- and time-saving facility.

The installation and maintenance of the down-draft system referred to is doubtless an expensive item, but it should be borne in mind that by this means locomotives can be fired without the use of the steam blower and that the elimination of noise as well as smoke and steam from the interior of the roundhouse is a most desirable feature.

The mention of cranes suggests the question as to whether one of the most important elements in the modernized terminal has not been overlooked in the presentation of this paper. That is the use of cranes, electric tractors and other means employed for removing and replacing heavy parts of the locomotive and for conveying materials about the terminal.

The Properties of Steam

AT the end of last year there was published in London a work entitled, The Properties of Steam and Thermodynamic Theory of Turbines, by Prof. H. L. Callendar, which has attracted a great amount of attention. *Engineering* says that the author's Royal Society papers embodied in this treatise "undoubtedly constitute the most illuminating and reliable work on the properties of steam accomplished by any engineer or physicist since the pioneering labors of Regnault, Rankine and Kelvin." The following abstract is made from articles in the issues of that journal for Jan. 21 and 28, 1921.

In the complete equation of state for gases and vapors

$$V - b = \frac{RT}{P} - c \qquad [2]$$

there is a term c known as the co-aggregation volume. It represents the diminution of volume due to the pairing of the molecules.

The problem of determining how this co-aggregation volume c varies with the temperature, pressure and volume of a gas has occupied the attention of physicists for years. The Van der Waals equation of state leads to a very complicated expression for c and moreover expresses the relation between the temperature, pressure and volume of a gas qualitatively only. It would hardly be going too far to assert that of late years the Van der Waals equation has been a hindrance rather than a help. It has tempted investigators to endeavor to include in a single formula all the properties of a body whether in the liquid or the gaseous state, right up to the critical point. This feat has not been accomplished for any single body, and the attempt to do so in the case of steam where reliable data near the critical point were wholly lacking has been ill advised at the best. This has been emphasized recently by a new and accurate determination of the critical temperature, which turns out to be some 9 deg. cent. higher than the value adopted by the German and American computers who have published elaborate tables on the properties of steam.

Some 20 or 25 years ago the properties of steam were considered as adequately established by the Regnault formula:

$$H = 1091.7 + 0.305\,(t - 32) \qquad [a]$$

Based on this formula, Professor Peabody devised his throttling calorimeter for estimating the quality of steam supplied to engines under test, but when it was used in certain tests it was found that the wetness of the steam supplied by the boilers as calculated from Regnault's formula persisted in coming out negative. In other words, the throttling calorimeter declared the steam supplied to be superheated when it was not. This led to an exhaustive investigation at McGill University by Professor Callendar, which showed conclusively that the Regnault formula was wrong.

German investigators substituted for it empirical formulas which neglected, however, to take into consideration the fact that there is a close connection between the thermal properties of steam and its specific volume. Because of this the elaborate tables compiled in America on the basis of German experiments and formulas are claimed to fail to satisfy the test which consists in that the work done in a given cycle should be the same whether it be measured on the temperature-entropy chart or on the indicator diagram.

Callendar attacked the problem in a different manner. He devised new and extremely accurate methods of determining total and specific heats and of determining with precision the law for the adiabatic expansion of steam. He also devised formulas to represent the properties of steam and laid down the principle that these formulas must be consistent with each other. Any formula for the total heat of steam must be consistent with Equation [2] *ante*, and with the experimentally demonstrated fact than the adiabatic expansion of steam is represented by the equation

$$PT^{-\frac{13}{3}} = \text{constant}$$

The adiabatic expansion of an ideal gas satisfying the equation $P(V - b) = RT$ can also be represented by a formula of this kind. The more usual formula in this case is $P(V - b)^{\gamma}$ = constant, but on substituting for $V - \gamma$, this takes the form

$$PT^{\frac{\gamma}{1-\gamma}} = \text{constant.}$$

Any adiabatic expansion is effected at the expense of E, the internal energy of the body. In the case of the ideal gas it is well known that this internal energy (expressed in ft-lb.) can be represented by the formula

$$E = \frac{1}{\gamma - 1} P(V - b)$$

where γ is the index in the usual formula for the adiabatic expansion of such a gas. The above expression represents, in fact, the work which can be done by the gas when expanded adiabatically down to zero pressure. Now so far as the internal energy of steam is due to the molecular velocities and spins, it must be capable of being represented in the same way. Hence in the case of steam we may write—

$$E = \frac{1}{\gamma - 1} P(V - b) + B$$
$$= \frac{10}{3} P(V - b) + B$$

The work done in an adiabatic expansion is equal to the change in the internal energy, and if B be constant this change of internal energy will be exactly the same as it would be in the case of an ideal gas having the same value of γ as steam has, and it is perhaps fairly obvious that the law for adiabatic expansion will then be expressed by the same formula.

Whether B is or is not constant is a matter for experiment. Since we cannot conveniently measure directly the internal energy of steam, these experiments are best made by determining the total heat H which is defined nowadays by the relation—

$$H = E + PV$$

This differs from Regnault's definition in that Regnault took no account of the energy required to drive his feed pump. In this equation all quantities of energy must, of course, be expressed in ft-lb units.

The difficulty of determining accurately the total heat of steam has been solved by Callendar, who did it by comparing the total heat of high-pressure steam with that of superheated steam at atmospheric pressure, which latter can be determined with considerable precision. In making an experiment the high-pressure steam is withdrawn down to atmospheric pressure through the equivalent of a porous plug and its temperature noted after passing this plug. In an operation of this kind the steam retains after its expansion its original total heat, and as the total heat of superheated steam at atmospheric pressure is known from the preliminary experiments made, a very simple method of finding the total steam at higher pressures is thus provided.

It is of interest to note that the results obtained by Callendar agree quite well with the unknown unextrapolated figures published by the German investigators and with direct determinations of specific heats made by Prof. Carl Thomas.

These observations show that within the experimental range B may be taken as constant. Callendar thus obtained the following formula for the total heat of superheated dry saturated or super-

saturated steam expressed in British thermal units (in this formula the pressures are taken in pounds per square inch):

$$H = \frac{13}{3}\frac{p}{777.8} \times (V - 0.01602) + \frac{0.01602}{777.8}p + 835.2 \ldots [b]$$

With this expression for the total heat the observed law of the adiabatic expansion of steam is satisfied, but it is also necessary that the equation of state be satisfied, namely,

$$V - b = \frac{RT}{P} - c \ldots\ldots\ldots\ldots\ldots\ldots [c]$$

This gives a clue as to the character of the variation of the co-aggregation volume with the pressure and the temperature, which is determined mathematically. The expression finally derived for [c] is quite a complicated one and involves a number of coefficients of which Callendar has shown that they are so small as to be negligible at ordinary pressures, though they may become important as the critical point is approached.

In this connection the physical meaning of the critical point is discussed. In general, if any liquid is exposed to a gas, some of the gas is dissolved. When the gas in question is its own vapor the rule still holds and Callendar has shown that the observed increase in the specific heat of water as the temperature rises is almost wholly accounted for by the latent heat of the dissolved steam. The amount of this dissolved steam present increases as the pressure of evaporation rises and hence the latent heat required to produce this dissolved steam increases with the temperature of the water and this occasions an apparent increase in the specific heat of the liquid.

For pressures not near the critical point but within the practical range the volume is given accurately by the expression (temperatures in centigrade degrees and pressures in pounds per square inch):

$$V - 0.01602 = 1.07061\frac{T}{p} - 0.4213\left(\frac{373.1}{T}\right)^{\frac{10}{3}}$$

The equation for the total heat of steam and that expressing the relation between the volume, temperature and pressure which are given above are fundamental and from them all other equations required may be derived. As an example, the original article shows how the expression for the entropy is derived and how and why this expression must apply also to dry saturated steam. The latter, however, is equal to $\phi_w + \frac{L}{T}$, where ϕ_w is the entropy of water at the absolute temperature T, and L is the latent heat of steam at the same temperature. If we equate these two expressions and solve the resulting equation for p, this (if Callendar's formulas are reliable) should be equal to the saturation pressure as determined by Regnault and others. The test is a very crucial one and it turns out that the agreement is extraordinarily close, the computed figures differing less from the results obtained by different experimenters than these do from each other.

Indeed, Callendar has shown that his equation for the saturation pressure can be put into a form which is with the exception of a corrective term depending on the co-aggregation volume is identical with the theoretical expression for an ideal liquid and vapor as deduced by Rankine in 1866.

Another test which any set of reliable steam tables should successfully pass is that the specific heat must be the same whether deduced from the total heat or from the pressure, volume and temperature. Since the specific heat at constant pressure can be expressed mathematically as—

$$\left.\frac{dH}{tH}\right]_P$$

but is also equal to the expression

$$\frac{1}{J} \times T \times \left.\frac{dV}{dT}\right]_P \left.\frac{dP}{dT}\right]_\phi$$

where the suffix P denotes that the volume is changed at constant pressure, and the suffix ϕ that the pressure is changed at constant entropy, that is, say, by adiabatic expansion.

It is claimed that it will be found on trial that all the tables based on the German formulas for the total heat and specific volume of steam fail to satisfy this test, the discrepancy being as much as 20 per cent, and that the only tables which do so are those based on Callendar's work.

Among other things, Professor Callendar in his treatise gives an analysis of Professor Stodola's experiments on the losses in a convergent-divergent nozzle. Stodola himself was not satisfied with the conclusions to which his own analysis apparently led, as this indicated a frictional loss of some 20 per cent, and the losses were distributed in a somewhat anomalous way. Callendar shows that when the supersaturation of the steam is taken into account the frictional loss comes out at from 6 to 10 per cent, which is a much more reasonable figure.

As regards the state of supersaturation in steam, Professor Callendar takes the view that after the Wilson line is crossed the steam temperature during the remainder of the expansion is that corresponding to the Wilson line, while the water temperature is the saturation temperature corresponding to the pressure. From this it follows that in the first approximation the Wilson line can be regarded as replacing the saturation line on the old theory and that formulas deduced on the hypothesis that the steam expands in thermal equilibrium require only a small adjustment to suit the actual conditions.

The trouble with expressing the phenomena attending the expansion of wet steam in thermal equilibrium is due to the great complication of the exact expression for their reheat factor. Professor Callendar finds, however, that it can be obtained with remarkable accuracy from the semi-empirical formula—

$$\frac{\epsilon}{\eta} = 1 + (1 - \epsilon)x$$

where ϵ denotes the efficiency ratio and η the hydraulic efficiency of the turbine, while x is equal to u, the adiabatic heat drop divided by $2(H_\phi - st)$. Here H_ϕ denotes the total heat at exhaust had the expansion been adiabatic, and $st = t - \frac{t}{300}$, where t is the final temperature centigrade. This formula will greatly add to the facility with which turbine tests can be analyzed, and in view of what has been said above should be capable of modification to meet the case of the expansion of wet supersaturated steam. In view of the fact that the total heat of steam in ft-lb. units is given by the relation—

$$H = \frac{\gamma}{\gamma - 1} \times P(V - b) + Pb + B$$

on neglecting b a formula of the type $P(V - b)^\lambda$ = constant, can be transformed into an equation of the type—

$$H - B = kP^m = \text{constant}$$

For superheated or supersaturated steam expanding with a hydraulic efficiency η, the value of m is $\frac{3\,\eta}{13}$. Callendar finds that an equation of the same form can be made to represent with great accuracy the expansion of wet steam in thermal equilibrium. In that case the value of m is fixed by the condition that

$$\frac{P_0V_0}{P_1V_1} = \frac{P_0{}^m}{P_1{}^m}$$

while k and B are determined by the initial and final values of H and P. This equation is very simple to apply and should also be suitable for the expansion of wet supersaturated steam. We are thus furnished with a new method of turbine analysis. The difficulties under which we have hitherto labored are well illustrated by the circumstance that after a most careful and extensive series of tests on a small reaction turbine made a few years ago in his laboratory by one of our leading authorities, the task of interpreting the records obtained had in the end to be abandoned in despair. (*Engineering*, vol. 111, nos. 2873 and 2874, Jan. 21 and 28, 1921, pp. 63–65 and 93–94, *tcA*)

[The statement made in the foregoing abstract to the effect that American steam tables based on German formulas are in error, in some respects as much as 20 per cent, is of course one for which the author of the articles is responsible. Similar but less specific comment appeared in an article on a new theory of the steam turbine, by H. M. Martin, in *Engineering*, July 5, 1918, which was quoted in the Survey Section of September 1918, p. 785.]

Short Abstracts of the Month

AERONAUTICS

The Leitner-Watts All-Metal Propeller. It is stated that all but one of the problems of the metal propeller have been solved in this device, and that one is weight. In their present form these propellers are very much heavier than corresponding wooden screws.

The blades are each made up in the form of a shell of sheet steel and the necessary taper in thickness is obtained by using laminated construction, there being three laminations—one at the top, the second about halfway between the tip and the boss, and the third at the root. The laminations are at present riveted together, but later on it is intended to employ electric spot welding.

The two halves of each blade are attached to one another at the edges only by welding, but in order to stiffen the shell thus formed small struts are placed between the two faces at intervals.

The method of inserting these struts is shown in Fig. 1. The struts are shouldered at both ends and the hole in one face of the

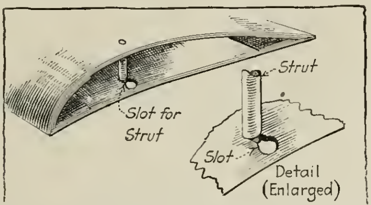

Fig. 1 Method of Inserting Small Struts between Front and Rear Faces of the Leitner-Watts All-Metal Propeller

blade is made just the right size to take the thin portion of the strut. In the other face of the blade is cut a hole large enough to accommodate the thick portion of the strut. From this hole runs a slot of a width corresponding to the shouldered portion of the strut. To place in position, the strut is inserted in the large hole, its other end being pushed into the small hole on the opposite face, and the shouldered portion is slid into the slot. The strut is then secured in position by soldering washers over the two strut ends.

The root of the blade is constructed in a very substantial manner. Balance of the blades is secured by using small balance weights carried on short lengths of tube secured to the inner end of the central plug in the blade root. These propellers have an adjustable but not a variable pitch, which means that the pitch angle of the blades can be altered over a wide range (10 deg. each way), thus making the propeller suitable for a number of different conditions by setting the pitch according to requirements. (*Aerial Age Weekly*, vol. 12, no. 22, Feb. 7, 1921, pp. 559–560, 3 figs., *d*)

AIR MACHINERY

Relation of Air Pressure to Drilling Speeds of Hammer Drills, H. W. Seamon. Data obtained in 1500 tests made by the United Verde Copper Co. to determine the most economical air pressure for the operation of hammer drills under varying conditions of use, and to investigate the variation in drilling speed at different air pressures.

Twelve models of drills, all of the wet type, were used at gage pressures ranging from 40 to 130 lb. per sq. in. Seven drills were of the heavy mounted class, three of the jackhammer type and two stopers. The drilling was done in massive sulphide ore of uniform hardness, the same face being used for all tests. Horizontal holes were drilled with the mounted machines and vertical holes with the stopers.

Shop measurements of the power of the drills were made on a Paynter rock-drill tester, which records the number of blows per minute and the strength of the blow, and the values thus obtained were assumed to be the same in the testing ground under the same gage pressures.

Tables are given in the original paper showing for each one of the drills tested the number of blows per minute, the strength of the blow, the horsepower developed, the drilling speed, the air consumption, the efficiency and the distance drilled, under air pressures varying from 40 to 130 lb. per sq. in.

From the figures obtained an empirical formula is derived for the "factor of desirability" of a certain type of drill in terms of its cost of operation and maintenance.

Analysis of the results obtained leads to the following general conclusions:

There is little or no increase in mechanical efficiency of the drills above 90 lb. pressure.

The distance drilled per air indicated horsepower is greatest for the jackhammer type at 90 lb., and increases at a slow rate for the other machines at the higher pressures.

The average thermal efficiency is greatest at about 95 lb.

The factor of desirability, while increasing as the pressure, shows a comparatively slow rate of increase for pressures above 100 lb.

The average drill is made to be used at a pressure of 80 lb., or less; using pressures much exceeding this will invalidate the present replacement agreements with the manufacturers, thereby increasing the upkeep cost.

The increased breakage at the higher pressures, with the consequent loss of time of the drill runner in changing or repairing the machine, would tend to reduce the factor of desirability, as this item of expense is not included therein.

The increased breakage of drill steel would tend to limit the pressure, although there are not sufficient data on this point to determine the maximum. (Abstract of paper presented at the New York Meeting of the *American Institute of Mining Metallurgical Engineers*, Feb. 1921, 14 pp. and 14 tables, *e*)

ENGINEERING MATERIALS

Effect of Temperature, Deformation, Grain Size and Rate of Loading on Mechanical Properties of Metals, W. P. Sykes. Researches conducted at the National Lamp Works to establish the relations existing between temperature and mechanical properties in molybdenum, nickel, and an aluminum-copper alloy. The molybdenum used was of the quality that is drawn into wire 0.003 in. in diameter for use as filament supports in incandescent lamps, and its chemical analysis showed less than 0.1 per cent of impurities. The nickel was obtained as 0.09-in. wire, annealed, of composition 99.8 per cent nickel and 0.15 per cent iron. Finally the alloy samples contained 3 per cent copper, 0.42 per cent iron, and 0.21 per cent silicon. Seven specimens of molybdenum, five of nickel and seven of the aluminum-copper alloy were tested. The individual specimens of each class were heat-treated and prepared in different ways.

Measurements were made of the tensile strength, reduction of area and elongation at temperatures varying from —185 to 1000 deg. cent. in the case of the molybdenum samples, and from —185 to around 600 deg. cent. with the nickel and aluminum-copper specimens. The results obtained are given in the original paper in separate tables for each specimen tested. Sets of curves are also constructed indicating temperature against tensile strength, elongation and reduction of area in each case, and photomicrographs of the metals at the place of rupture are analyzed and interpreted.

The following general conclusions are formulated:

Excluding allotropic changes and other specific characteristics, all metals possess the same fundamental properties and those exhibited by any one metal are functions of the temperature at which the observations are made. The maximum reduction of area by fracture in tension occurs in a piece of metal in which single grains occupy the entire cross-section. In the case of two aggregates, the one of smaller grain size suffers the greater reduction. The ultimate result of decreasing temperature is a complete loss of ductility and probably eventually a reduction in tensile strength. Brittleness is first observed in metals having equiaxed structures.

The smaller the grain size of a sample the lower is the temperature to which ductility is preserved. Deformation of a metal below its annealing temperature makes its maximum ductility at any temperature below that of working less than that of the same metal in the unworked condition. But the worked sample will retain its power of elongation to a lower temperature. (Abstract of paper presented before the *American Institute of Mining and Metallurgical Engineers* at the New York Meeting, Feb. 1921, 35 pp., 38 figs., *e*)

Tests at Mellon Institute on Heat-Insulating Materials

Characteristics of 85 Per Cent Magnesia as a Non-Conducting Covering, Edward Weidlein. The data presented in this report were obtained during the course of an investigation conducted for the Magnesia Association of America by the Mellon Institute of Industrial Research, where the author holds the position of associate director.

The object of the investigation was to obtain facts regarding the

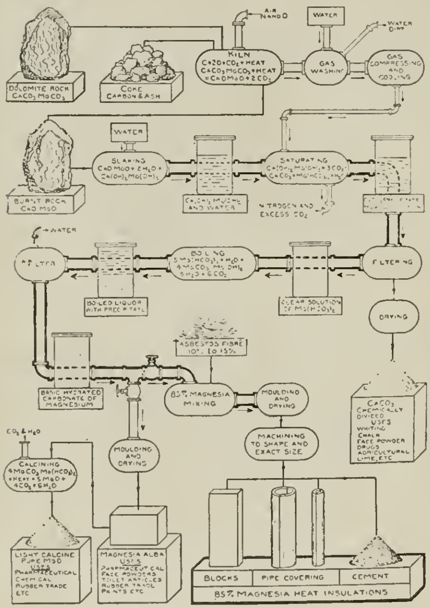

Fig. 2 Flow Sheet Showing Steps in Production of 85 Per Cent Magnesia

value of 85 per cent magnesia as a heat-insulating material. It is stated that the name "85 per cent magnesia" denotes the fact that the covering contains 85 per cent of basic magnesium carbonate. The remaining 15 per cent is asbestos, which is introduced as a binder to insure the required structural strength and durability. The flow sheet shown in Fig. 2 illustrates the method of manufacturing this product. The value of 85 per cent magnesia as a heat-insulating material is increased greatly by the interlacing and felting together of the crystals to produce a block of magnesia containing 90 per cent of voids, which take the form of exceedingly small air pockets.

At the Mellon Institute an investigation of heat loss from bare pipes was carried out with the results given in Fig. 3, where the full curves show heat losses from bare pipes as predicted from Péclet's formula, and the dotted curve and points indicate the experimental results obtained by various investigators. The Péclet values agree closely with the experimental findings and can be used safely.

Fig. 4 gives results of tests with pipes insulated with five different makes of magnesia coverings in 1-in., 2-in. and 3-in. thicknesses. The comparison with Fig. 3 will show a striking contrast between the losses from the bare pipe and the losses from covered pipes, and the difference increases with the temperature because the loss from bare pipe increases much more rapidly in proportion than the loss from covered pipe.

Further tests have shown that if the covering is alternately wetted and dried, the average value is the same before and after wetting and drying, and the treatment apparently does not effect the mechanical strength of the covering.

Tests on several old magnesia coverings have shown that the heat-insulating capacity slightly increases with time in some cases, and falls off materially in other cases, this latter taking place particularly where the covering happened to be saturated with oil.

As regards the influence of covering on rusting of steam pipes, the results of tests indicate that pipe coverings in general, especially if alkaline in composition, do not of themselves promote rusting on steam pipes when they become wet. On the contrary, they are claimed to act as a protecting coating since the oxygen does not get into intimate contact with the surface of the pipe. But an electric current flowing through the covering may either promote rusting of the pipe or it may retard corrosion, depending on the direction in which it is flowing. The greater the current flowing the greater will be the rusting effect. (Paper presented at the recent New Orleans Meeting of the American Institute of Chemical Engineers, abstracted through *Heating and Ventilating Magazine*, vol. 18, no. 2, Feb. 1921, pp. 30–34, 11 figs., *eA*)

Static and Dynamic Tension Tests on Nickel Steel, J. J. Thomas and J. H. Nead. Experimental investigation at Watertown Arsenal, Watertown, Mass., of the relation between static

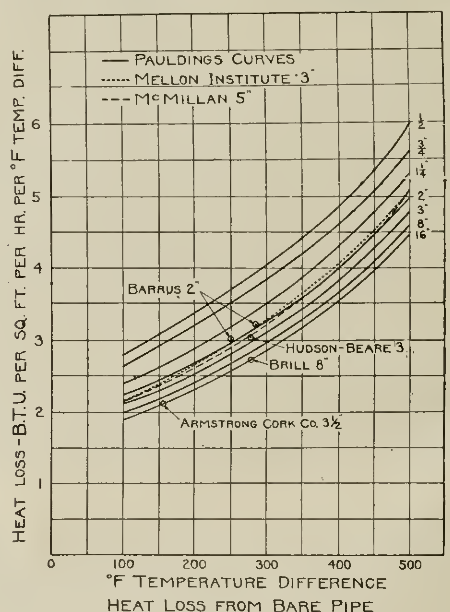

Fig. 3 Curves of Heat Losses from Bare Pipes

and dynamic tensile tests as measured by the work required to break test specimens slowly in a tensile testing machine, and rapidly by means of a falling weight. It was desired to ascertain the part played by ductility under different rates of application of load.

Five pieces of nickel steel, 0.505 in. in diameter and 10 in. gage length, containing 0.42 per cent carbon, 0.48 per cent manganese, 0.09 per cent silicon, 0.035 per cent sulphur, 0.035 per cent phosphorus, and 3.20 per cent nickel, were used. One piece was annealed, one was oil-hardened, and three were hardened and

of varying hardness, were then tested slowly in tension and the stress-strain diagram plotted. Five similar pieces were also tested in an impact machine with a recording device for drawing the stress-strain diagram.

From tables in the original article it appears that both the specimen that was quenched but not drawn, and the one that was drawn up to 300 deg. cent., required very little work to break under either a radidly or a slowly applied load. The figures obtained for elongation and reduction of area indicate that ductility is independent of the rate of application of the load. Comparing the corresponding values of work under the two tests, it is concluded that as the elongation is about the same and the work is noticeably greater, the resisting force of the metal is greater for suddenly applied loads.

For low drawing temperatures both ductility and work of rupture are very low. As ductility increases the work of rupture

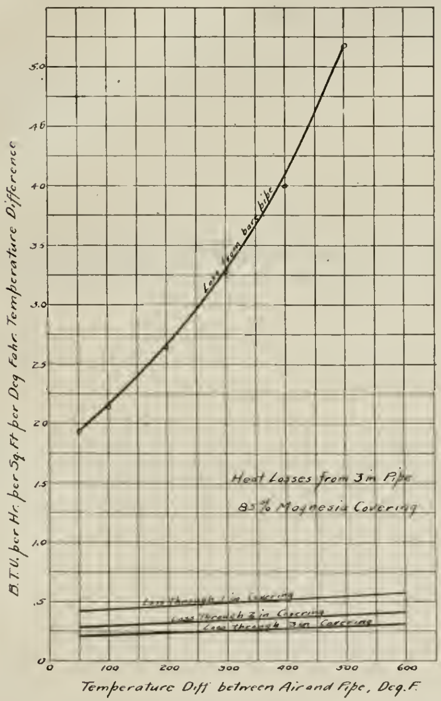

Fig. 4 Curves of Heat Losses from Pipes Insulated with 85 Per Cent Magnesia

increases. For hard steels, a small force, less than the elastic limit, if applied with sufficient velocity, develops enough kinetic energy to cause rupture. It is evident, therefore, that force alone is not the proper criterion by which to measure the strength of material. The work unit is more valuable as a measure of strength, and as ductility is an indication of the work required to rupture it is wise to specify a high ductility for all parts subject to shock. Ductility as measured by elongation and reduction of area in the ordinary tension test is important not for the part it itself plays but as an indication of strength as measured by work units. Steel is in its best condition when quenched and drawn just under its critical temperature.

The results of the static test demonstrate that for a slowly applied load nickel steel is hard and brittle when drawn at temperatures of 300 deg. cent. or lower. Beyond this point, however, a real softening effect is obtained. For low drawing temperatures the maximum strength, yield point, and elastic limit, occur at the same point, thus giving a brittle steel that fails without removed, or to the hard martensitic structure of the steel. For higher drawing temperatures there is a marked increase in the ductility and a greater resistance to shock. The modulus of elasticity increases slightly with the higher drawing temperatures, but this increase is probably too slight to have a commercial value. (Paper presented before New York Meeting of the *American Institute of Mining and Metallurgical Engineers*, Feb. 1921, 13 pp., 19 figs., *e*)

FUELS AND FIRING

Catalytic Heating, R. Villers. Description of a device employing flameless combustion and designed by two French engineers, Louis Lumiere and J. Herck.

In this apparatus gasoline is used as a fuel and is decomposed by catalysis into water vapor and carbon dioxide, platinum in the presence of air being used as a catalyzer. The first employment of these heaters was found on military aeroplanes in winter when it was necessary to keep the water in the radiator warm and when it was not desirable to use an open flame because of the danger of fire. The construction of the device is diagrammatically shown in Fig. 5. A layer *A* of asbestos impregnated with platinum serves as the base of the cone *B* held by its small end against a similar cone *C*, which, in its turn, forms the top of a reservoir *D*. This reservoir is filled with a spongy material, such as cotton, which, by absorbing the gasoline prevents there being an excess of the liquid. A wick *E* extends into this reservoir and causes the evaporation of the liquid into the chamber between the walls of the upper cone and the platinized asbestos *A*. Once started by heating the platinized asbestos to the proper temperature, the action continues indefinitely as long as there is fuel, and produces a temperature of about 250 deg. cent. (482 deg. fahr.) in the top layer.

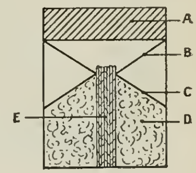

Fig. 5 Thermix Catalytic Heater

The preliminary heating of the platinized asbestos required to start the operation of the device may be accomplished by putting a few drops of gasoline or alcohol upon it and lighting them, or by an electric resistance. The advantage claimed for this device lies in the fact that the combustion takes place without the production of any flame, odor, or exhaust products, in addition to which the efficiency of combustion is very high because of the fact that the gasoline is decomposed completely without any residue and is claimed to develop its entire heating value without any losses. To extinguish the heater, all that is necessary to be done is to shut off the admission of air by means of a special cover.

The apparatus designed in accordance with the principle explained above has been placed on the market in France under the name of "Thermix." (*La Nature*, no. 2438, Dec. 25, 1920, pp. 415–416, 5 figs., *d*)

Furnace in which Air is Forced Between the Bars

The Turbine Patent Furnace. Description of a furnace designed on the principle of the impulse turbine. In its construction the air trough corresponds to the nozzle and the fire bars to the blades of the turbine. The air for combustion is forced between the bars which offer but slight resistance and the design is such that each fire bar receives an equal amount of air which is distributed through the narrow air spaces in the form of fine spray. Fig. 6 shows the furnace applied to a Babcock water-tube boiler. Its outstanding feature is the dead plate (7 in the figure) which slopes downward, thus bringing the furnace from 3 in. to 5 in. lower than the ordinary level and giving more room for combustion in the furnace proper. Air is admitted through the chamber as required, through the door fixed under the first bridge. The fire bars are constructed with interlocking lugs so that they cannot be displaced by the rake, and the air spaces slant upward and backward, reducing the amount of fine ash or coal that drops through to

a minimum. The bottom lugs project forward and intercept the air, thus insuring an evenly diffused supply throughout the fire. The grate consists of from four to six furnaces, each receiving its own air supply, which besides insuring an evenly burning fire makes the use of steam jets for creating the draft very simple.

TABLE 1 DATA OF COMPARATIVE TESTS OF TURBINE PATENT FURNACE AND FURNACE WITH ORDINARY FIRE BARS

Type of Furnace	Ordinary Bars	Turbine Furnace Bars
Duration of test, hr	6	6
Fuel average, lb. per hour	1,045	1,506
Ash, per cent	17.8	16.0
Total water evaporated, lb	25,800	50,800
Average steam pressure gage, lb. per sq. in.	152	157
Average feed temperature, deg. fahr	210	250
Lb. water per lb. fuel as fired	4.11	5.63
Lb. water per lb. fuel from and at 212 deg. fahr.	4.34	6.00

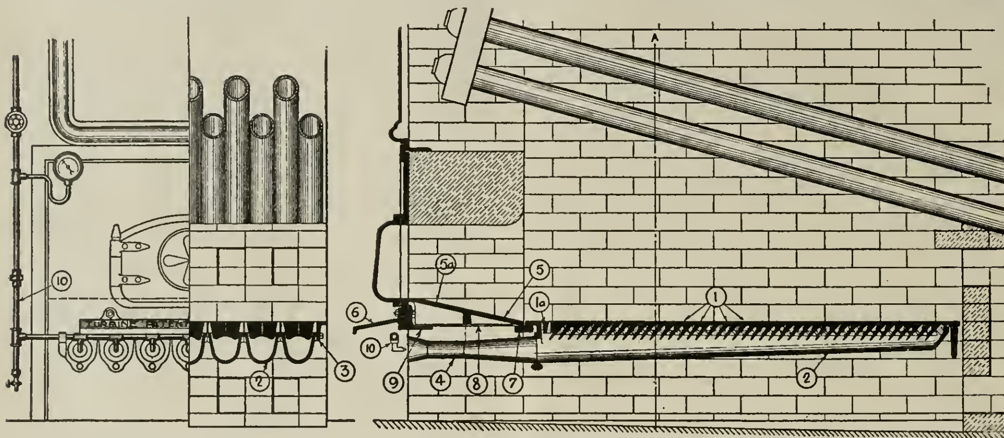

Fig. 6 Turbine Patent Furnace as Applied to a Babcock Water-Tube Boiler

Table 1 is claimed to represent results of a comparative test of the turbine furnace and ordinary fire bars carried out recently at the Birmingham Works of the General Electric Company. (*The Electrical Times*, vol. 59, no. 1525, Jan. 6, 1921, p. 11, 2 figs., *d*)

HEATING AND VENTILATION (See Engineering Materials)

HYDRAULIC MACHINERY (See Lubrication)

INTERNAL-COMBUSTION ENGINES

The Carbonization of Lubricating Oils in Internal-Combustion Engines, Frederic H. Garner. The mechanism of carbonization of oil is described by the author as follows: The major part of the oil getting into the combustion space is probably present as a fine spray. The heat of the explosion may be sufficient to completely burn the smaller droplets, but the larger droplets will be only partly burned by the momentary heat of the explosion. Thus carbon and asphaltenes are formed from the oil. If the carbon so formed is light in texture, it will be blown out of the exhaust, but if dense asphaltic material is formed in the ensuing compression stroke, it will tend to adhere to the piston face and cylinder walls, giving carbon deposits.

This makes the suction stroke the most important of the whole cycle from the point of view of lubrication, as the leakage of oil occurring during the stroke is the origin of the carbon deposit. On the other hand, as carbon formation is determined mainly by the character of the oil spray in the combustion space rather than the oil film on the walls, the rapid carbonization of oil, that is, its coking value, will be a more important factor in the testing of lubricating oils for internal-combustion engines than the gradual carbonization at lower temperatures.

In an investigation carried out by the writer the evaporation losses and degree of carbonization over a wide range of temperatures were determined for a series of lubricating oils from petroleum representing asphaltic and paraffin-base crudes, and the means used in the investigation are described in some detail. (*Petroleum Times*, vol. 5, no. 107, Jan. 22, 1921, pp. 93–95, *e*)

LUBRICATION (See also Internal-Combustion Engines)

Lubrication of Hydraulic Turbines, Niagara Falls Power Company. The lubrication of the recently installed hydraulic turbines of the Niagara Falls Power Company is of great interest both because of the tremendous size of the units and because of their modernity. There no striking novelties of any kind, but the installation is of interest as one in which great care has been taken to create the best possible conditions of lubrication. Special attention is called to the method of using oil in the governors.

In these turbines the thrust and upper guide bearings are supplied with oil by separate pipes leading from a storage tank of 2000 gal. capacity in the upper part of the power house, the feed to the bearings being by gravity. The pressure obtained is not only sufficient but actually somewhat excessive and a regulating valve and oil meter are installed in the thrust-bearing line to regulate the supply. After passing through the bearings the oil from all the sets runs to a common header and thence to the filtering system. An oil of 180 sec. (Saybolt) viscosity at 100 deg. fahr. has been found suitable for the bearings, but it must be kept so as to be non-emulsifying with water and not to break down on continual use. It is stated that the oil and bearings have been so thoroughly developed that the oil emerging from the thrust bearings shows a rise in temperature at full load of only 6 deg. fahr. and the loss in power due to bearing friction is only 26 hp. or seven hundredths of one per cent of the power of the unit.

Another place where oil is used is in the governors which control the amount of water flowing into the turbines. This control is effected by 20 swinging guide vanes situated around the circumference of the runner. These vanes are operated by means of a ring which in turn is actuated by pistons in large cylinders. The displacement of these pistons is controlled by a governor.

Originally oil was used as the actuating medium in these pistons, but as it is almost impossible to prevent leakage, not only was a large amount of oil wasted but the compartment where the gates were installed soon became slimy and unsightly. This condition was obviated by using a mixture of soluble oil and water in place of oil alone. It was found that a one per cent mixture of soluble oil in water was sufficient to furnish adequate lubrication to the moving parts and prevent rusting and corrosion of the metal. (*Lubrication*, vol. 6, no. 11, December 1920, pp. 1–8, 9 figs., *dg*)

Chemistry of Lubrication—The Deeley Oil-Testing Machine

Friction and Lubrication, R. Mountford Deeley. Description of experiments on lubrication and of a special machine designed by the author for testing oils, accompanied by general remarks on the mechanism of the phenomena of lubrication.

The friction experiments described in the article were made under conditions which insured that the surfaces should be in actual contact, and it is claimed that any differences in the frictional coefficients shown by the oils tested must have resulted from the contact of oily metals, and not from the free molecules of the liquid itself. The experiments were made with the machine shown in Fig. 7.

Three pegs, each $^5/_{32}$ in. diameter, rested upon the flat surface of a disk of metal which could be slowly rotated. These pegs were secured concentrically to an upper disk which could be weighted as desired and which actuated a spindle to which a spiral spring and recording finger were attached. When the lower disk was rotated the pegs were carried with it by friction until the surfaces slipped owing to the stress on the spring, and the finger then gave the value of the frictional stress reached. To damp the oscillations of the finger the spindle to which the finger and spring were attached was geared to a small train of wheels, the freely revolving end wheel of the series having a weighted rim to increase its inertia. When measuring the static coefficient a pawl and ratchet were thrown into gear with the indicating finger to prevent it from moving toward zero if an oil film should form and the surfaces part. By very slowly moving the driving handle the finger was quickly brought to the position giving the static coefficient. The movable disk upon which the pegs rested lay in a circular dish, which could be filled with oil and slowly rotated.

To insure clean surfaces the metals were ground in water with flour of carborundum and then carefully polished and dried. Such clean surfaces are very sensitive to any contaminating agency.

One of the interesting things found was that while animal and vegetable oils largely displaced mineral oils from surfaces, mineral oils would not displace animal or vegetable lubricants. Surface may be contaminated with oil and yet not be wet. The coefficient of friction—static—varies very much with the condition of polish of the surfaces, as well as with the nature of the contamination.

When the surfaces are properly ground and polished and no lubricant is used, the static coefficient becomes greater and greater as the surfaces continue to rub against each other.

The tests have shown that the friction depends not only on the oil used but on the metals.

Table 2 gives the static coefficients and efficiencies of a number of oils tested between mild steel and cast iron and mild steel and gun metal. The percentage efficiency e has the value

$$e = 100 - (\text{static coefficient} \times 100).$$

There is a marked difference between the friction of the various oils when the mild steel is opposed respectively by cast iron and gun metal. Rape and olive oils give the best results and mineral oils the worst, castor coming between the mineral lubricants and the rest. Rape and olive are of equal value between mild steel and cast iron, but rape is the better between mild steel and gun metal.

TABLE 2 COEFFICIENTS OF FRICTION AND EFFICIENCIES OF VARIOUS LUBRICANTS

	Mild steel on cast iron		Mild steel on gun metal	
Lubricant:	Static coefficient	Efficiency, per cent	Static coefficient	Efficiency, per cent
Clock oil	0.271	72.9	0.275	72.5
Bayonne	0.213	78.7	0.234	76.6
Typewriter	0.211	78.9	0.294	70.6
Victory red	0.196	80.5	0.246	75.4
F.F.F. cylinder	0.193	80.7	0.236	76.4
Manchester spindle	0.183	81.7	0.262	73.8
Castor	0.183	84.7	0.169	83.1
Sperm	0.127	87.3	0.189	81.1
Trotter	0.123	87.7	0.152	84.8
Olive	0.119	88.1	0.196	80.4
Rape	0.119	88.1	0.136	86.4

The value of such a test as an indication of the lubricating value of an oil depends entirely upon the mode of preparing the surfaces.

The author comes to the conclusion that the oil film formed between the metals is really a combination between the molecules of the lubricant with the molecules of the metallic surfaces. He believes it is possible that the molecules of a liquid lubricant or those of a lubricating grease penetrate the metal for some considerable distance and form on its surfaces a comparatively thick film of a compound which acts as a lubricant.

In his estimation the unsaturated molecules of the lubricant seem to attach themselves to the molecules of the metals they wet and form skins capable of preventing the free molecules of opposing metallic surfaces from adhering. If such be the case it is reasonable to suppose that friction coefficients between such metallic skins would vary with the metals in contact as well as with the nature of the oil. (Preliminary Report communicated to the Lubricant and Lubrication Inquiry Committee of the Department of Scientific and Industrial Research, Dec. 5, 1918. Not previously published. Abstracted through *The Engineer*, vol. 131, no. 3395, Jan. 21, 1921, p. 78, 1 fig., *etA*)

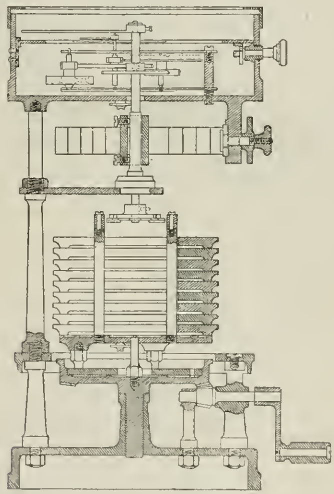

Fig. 7 Deeley Oil-Testing Machine

In connection with the foregoing abstract it is desirable to call attention to an editorial in the same issue of *The Engineer*, p. 74, under the title, Is Lubrication a Chemical Phenomenon?

In this editorial is reported a statement made by Mr. Deeley personally to the writer thereof to the effect that the oil film which he considers a compound formed by the oil with the metal is not a mere mixture or interlacing of the molecules, but is a definite union attributable to the action of the interatomic forces. In other words, it completely and exactly fulfills our conception of a chemical compound and in the case of a fatty lubricating oil may conveniently be referred to for purposes of discussion as oleate of iron, copper, cupro-tin, etc.

In this connection it is to be noted that common soap is formed by the union of fatty acids with sodium or potassium. The alkali can, however, be replaced by various other metals. Thus "soaps" formed by the union of fatty acids with iron, nickel, cobalt, zinc, magnesium, aluminum, copper or mercury are possible, and are actually made and used for a wide range of industrial purposes. The suggested union of the oily molecules with the molecules of the contacting surfaces in a partially lubricated bearing is thus not a chemical absurdity so long as we confine ourselves to animal or vegetable oils. In the case of mineral lubricating oils, however, the nature of the suggested compound is less readily pictured, although it is possible, by means of Mr. Deeley's theory, to propound an explanation of the facts reported by Messrs. Wells and Southcombe—in support of their "germ" theory—regarding the addition of small quantities of free fatty acid to mineral lubricating oils which was described by them in a paper before the Society of Chemical Industry (*Journal of the Society of Chemical Industry*, cp. Mechanical Engineering, June 1920, p. 356).

MACHINE PARTS (See also PUMPS)

Locking Ratchet Device for Trolley-Car Brake Handle

THE THOMAS PATENT RATCHET DEVICE. One of the important parts of equipment which have undergone no improvement since the horse-car days is the locking ratchet device at the bottom of the driver's brake handle. The original method of kicking a dog or pawl into gear with the ratchet wheel at the bottom of the brake spindle is still universally employed. A new type of this device is adapted to suit the double-spindle type brake gear largely used on various tramways.

It is claimed that this brake ratchet enables the driver to apply his brakes more quickly and to "feel" the brakes better, thereby reducing the wear and cost of brake shoes and wheel tires, and also preventing skidding of wheels. In case of emergency the driver can devote his entire energies to applying the brake, without having to worry about engaging the ratchet dog and pawl with his foot, as at present. Since the ratchet wheel is held by four ratchet dogs or pawls instead of one, as at present, the risk of the brake gear being released through wear is reduced. The foot pedal is provided with a cover to prevent passengers treading on it, thus releasing the brake gear when the car is at rest. The ratchet device thus presents very marked advantages over the existing type and it is anticipated that it will be widely adopted for tramway hand brakes. In this connection the device illustrated, which was developed in England, is of interest.

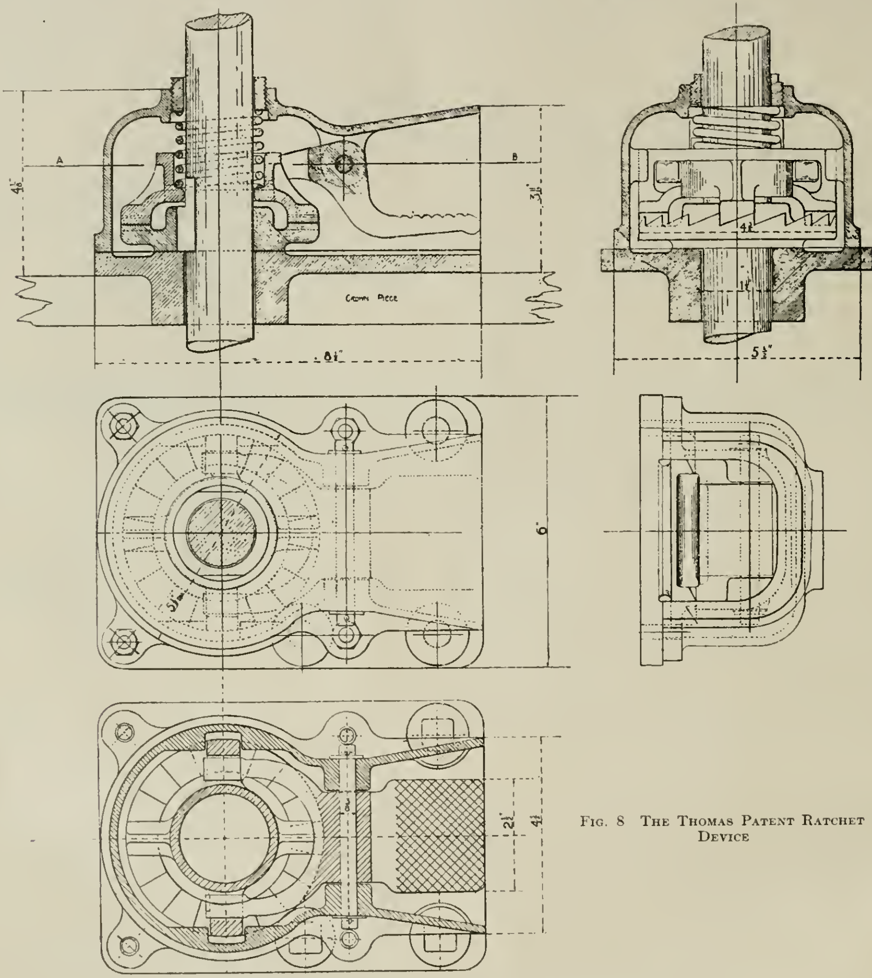

FIG. 8 THE THOMAS PATENT RATCHET DEVICE

shown in Fig. 8. It consists of the usual ratchet wheel, keyed on to the brake spindle, but instead of the teeth being on the side or edge of the wheel as at present, they are on the top and are of the rack type. Engaging in this wheel is a four-tooth dog wheel or pawl, which is held in position by a coil spring surrounding the brake spindle, and prevented from rotating by projections which engage lugs on the inside of the casing. To apply the brake on a car fitted with this new device, it is only necessary to turn the brake in the "on" position. A foot pedal (almost flush with the floor) operates a fork, which lifts the four-toothed wheel or pawl free of the ratchet wheel, thereby allowing the brake gear to be released. This foot pedal can also be made to slide sideways instead of being pressed down. All this gear is encased in a dust-and-grease-tight box, which insures protection from dirt. This fitting can be (*The Tramway and Railway World*, vol. 49, no. 3, Jan. 13, 1921, pp. 25–26, 1 fig., *d*)

There has been some decline in the use of vanadium in automobile steels, but experiments made with the metal in the production of high-grade non-ferrous alloys are reported to have been highly successful.

MACHINE SHOP

Electric Rivet Heaters. During the war both in this country and in Europe several types of electric heaters were developed. Such heaters work somewhat like electric resistance-welding machines and consist essentially of a static transformer furnishing a heavy current at a low voltage (in America, 5 and $2^1/_2$ volts), and means for holding the rivets. The heating takes place with great rapidity, but in order that there may be no delay the machine is designed to take two or three rivets at once, so that there is always at least one fully heated rivet ready for use. In some ways the three-rivet machine has an advantage over the two-rivet, since with three sets of electrodes rivets can be placed and removed when they are hot without having to operate a switch, as the two rivets which remain in position insure that the circuit is not actually broken.

In British machines plug switches are used to obtain the proper currents for each size of rivet. With a little practice the operator soon acquires the knack of putting the plugs in the proper holes for the particular class of rivet to be heated. It is stated that steel rivets $^5/_{16}$ in. in diameter can easily be heated at the rate of 1000 per hr. and $^1/_2$-in. diameter rivets at the rate of 600 per hr.

Table 3 is of interest as showing the output and power consumption with rivets of various kinds. (*The Railway Engineer*, vol. 42, no. 492, Jan. 1921, pp. 23–24, 1 fig., *de*)

TABLE 3 OUTPUT AND POWER CONSUMPTION OF ELECTRIC RIVET HEATERS

Rivets	Output per Hour	Maximum Power
$^5/_{16}$ in. × $^3/_4$ in.	600	
$^1/_2$ in. × $1^1/_{16}$ in.	250	6 kw.
$^9/_{16}$ in. × $1^1/_2$ in.	100

Hack-Sawing Machine of Novel Design

New Hack-Sawing Machine. Description of a power hack saw recently placed on the market by an English firm. The machine is very heavy, having a weight of 580 lb. and is designed to cut bars up to 6 in. in diameter.

The cut takes place on the backward or draw stroke, feed being effected by an adjustable weight carried on the top of the extended arm. On the forward, non-cutting stroke, the saw is relieved in a somewhat unusual manner. As seen in the arrangement, Fig. 9, the extended arm B, on which the saw frame is carried, is suspended by means of a roller chain from a spring-loaded drum A. Around a portion of this drum a number of fine ratchet teeth are cut, which are alternately engaged and disengaged with a pivoted pawl seen on the under side. During the forward, non-cutting stroke, the two members are engaged, consequently the drum is locked, the attached roller chain holding the extended arm stationary, and the saw is clear of the work. At the end of the stroke the pawl is disengaged, which allows the drum to be turned sufficiently to lower the frame on to the work, when the cut is freely effected, due to the weight mentioned. The alternate engaging and disengaging of the pawl is effected by means of a cam mounted on the crank driving shaft, which is in contact with a roller (not shown) carried in the rocker arm C. During the forward stroke the rocker arm is raised, and by reason of unequally weighted ends the pawl, pivoted thereon, drops into engagement, thus locking the drum and transferring the lifting to the saw frame. As the rocker arm is lowered at the end of the stroke, the outer end of the pawl makes contact with the adjustable stop E, Fig. 9, and is thus tilted clear and releases the drum. The drive, as mentioned, is by tight and loose pulleys, which replace the usual dog-tooth driving clutch. At the end of a cut the belt is automatically moved over on to the free pulley, thus stopping the machine. The belt fork is attached to a tension spring, which always tends to draw it over to the free pulley side. On moving over the belt fork by hand to start the machine, it is retained in position by a catch and is released at the completion of a cut through an abutment striking the lower end of the catch as the frame drops forward. (*Machinery* (London), vol. 17, no. 435, Jan. 27, 1921, p. 524, 2 figs., *d*)

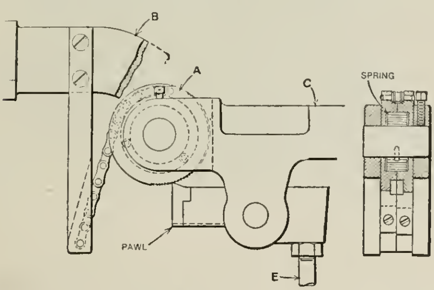

Fig. 9 New Hack-Sawing Machine. General Arrangement Showing Method of Relieving Saw During the Forward, Non-Cutting Stroke

MACHINE TOOLS

British-Made Full-Automatic Screw Machine

The "Empire" Full-Automatic Screw Machine. Description of a small automatic machine of British design and manufacture, an unusual feature of which is that it can be set up to produce two pieces for each complete revolution of the camshaft, thus doubling the capacity. A full description, however, cannot be given here, as the illustrations are not suitable for reproduction.

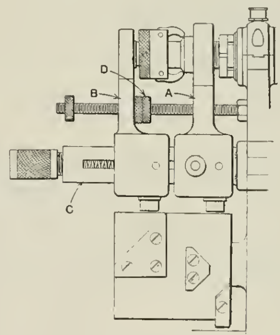

Fig. 10 Stock-Feed Mechanism of the "Empire" Automatic Screw Machine

The stock-feed mechanism is shown in Fig. 10. The collet is of the push-to-close type, and is controlled by the usual fingers and coned sleeve. This is operated by the bracket A, in turn controlled by the cams on the cam drum immediately below. The feed fingers in the spindle are operated by the bracket B, which is kept pressed toward the headstock by a spring housed in the bracket carrier C. The stock-feed cam on the cam drum thus draws the feed fingers back over the stock against the spring in C, and the nut and lock nut can be set to control the extent of the return movement, and consequently the amount of stock fed; the adjustment of the nuts D can therefore be used in certain cases instead of a stop in the turret, leaving all six turret stations free for tools.

Very effective overrunning die and tap holders are supplied for use in the turret; in addition to releasing in the usual manner, a spring blade bears on the holder and prevents rotation during withdrawal of the tap or die when the machine is reversed.

The machine throughout is substantial in design, and the idle movements of the turret cross-slide and reversing clutch are very rapid, allowing very close setting. If the machine is cammed for dealing with one piece per camshaft revolution, two threading operations can be undertaken, in addition to forming, drilling and parting, but where fewer operations are required the camming can be arranged to give two pieces for each camshaft revolution.

The gear train between the camshaft worm drive and the feed shaft from the planetary gear allows of ten feed changes, so that with the standard turret slide cams supplied a great variety of work can be undertaken. Setting up is very straightforward, and all adjustments can be made without going to the rear of the machine. By means of a double countershaft with cone pulleys, twelve spindle speeds are possible.

The capacity is up to $^1/_2$-in. stock, and the maximum length that can be turned is $1^1/_2$ in., although the maximum stock feed is $2^1/_2$ in. A pump, capacious suds tray and sump are provided.

The turret slide-cam drum has three T-slots, into which fit tenons turned out of the solid with the standard cams which are manufactured in ring form and afterward cut out as required. T-bolts secure the cams in the position desired, but the tenons take all side thrusts during operation and prevent the bolts from loosening.

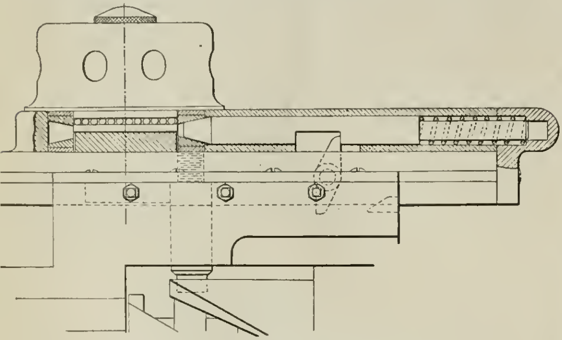

Fig. 11 Turret Indexing Mechanism of the "Empire" Automatic Machine

The turret indexing mechanism is shown in Fig. 11, and the substantial proportions and bearing surfaces of the indexing pin will be noted; the pin and indexing bushes are hardened and ground. The turret is supported below by a ball-bearing thrust washer. The cross-slides are positively advanced by cam levers and standard cams secured to a cam disk immediately below; the front and rear slides are independent and are spring-returned. (*Machinery* (London), vol. 17, no. 434, Jan. 20, 1921, pp. 492–493, 5 figs., *dA*)

Large Form-Grinding Machine

Bryant Form-Grinding Machine, Ellsworth Sheldon. This machine is said to be capable of regularly grinding pieces 10 in. long and of any diameter up to 12 in., by feeding the wheel straight toward the center of the work with a traverse of only $^1/_8$ in., and even this slight movement may be dispensed with, if necessary.

The machine is a development of the "bar" type, but the usual principle has been reversed. The bar carries the work and the wheel is mounted upon the bed in a stationary position. The wheel head when once set for the work in hand has no further movement until wheel wear makes it necessary to reset it. The movement of the work toward the wheel, the feed movement, is obtained by swinging the work carrier which is suspended from the bar.

Not only are cylindrical pieces of work reduced sufficiently to remove irregularities and make them round and smooth, but work having several diameters is produced with almost equal facility, each piece being exactly like every other piece and finished in a matter of seconds as regards grinding time and to limits of accuracy comparing favorably with other grinding methods.

Fig. 12 shows the various movements of the machine. The work centers are carried in the frame *AA* suspended from the main bar *B*, which latter is the feature that gives to the Bryant type of machine its name. The center at the driving end does not revolve, nor has it any adjustment endwise, except as the whole frame is moved. The rear spindle, which is a sleeve, may be adjusted longitudinally for a distance of 12 in. to accommodate various lengths of work and, in whatever position it may be, is firmly clamped to the lower member of the frame *AA*, the latter corresponding to the cross-slide of other types of machine.

An inner spindle, carrying the tail spindle, has a limited movement endwise for the purpose of mounting and demounting the work. This movement is controlled by the lever *C* through a spring-supported cam that holds the tail center strongly in place, while still allowing it to recede as the work expands under the influence of the heat generated by the grinding operation.

The bar *B* slides, and also turns, in adjustable bearings supported by the frame of the machine. Telescoping sleeves upon the bar protect the bearings from dirt and particles of abrasive. Endwise movement of the bar, of course, causes a traversing movement of the work across the face of the wheel, and the swinging movement provides for feeding the work to the wheel.

The bracket *D* is permanently fastened to the base of the machine and carries the cross-feed screw and sizing mechanism. The inner end of the cross-feed screw carries a hardened bearing shoe, upon which rides a bearing bar fastened to the carriage and held at all times in contact with the shoe by heavy counterweights. A pawl engaging with the ratchet *E* automatically turns the latter forward until it is disengaged by a shield that partly covers the ratchet wheel. A graduated dial enables the operator to set the shield to disengage the pawl at any predetermined point.

The machine is semi-automatic in its operation in so far as, after the work has been ground to a specified diameter, the wheel is automatically withdrawn from the cutting position. This action insures a very close duplication of size, as the grinding time of the wheel, after it has reached a positive stop, is exactly the same on every finished piece. That is to say, the length of time that the wheel is allowed to grind after reaching a positive stop for a set diameter is the same for each piece ground.

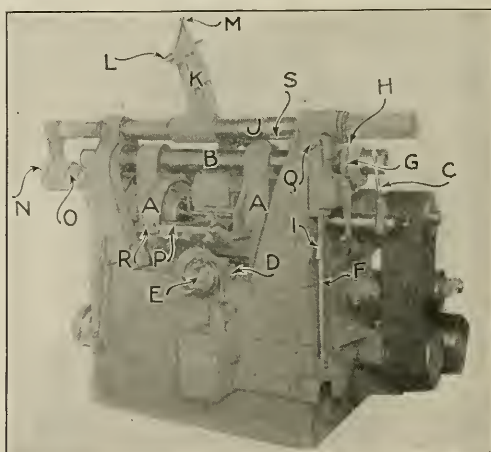

Fig. 12 Bryant Form-Grinding Machine, Front View

Traversing movement is transmitted to the bar *B* by means of an eccentric near the upper end of a vertical shaft, to be seen at *F*. The eccentric straps are connected to the clamping collar *G*, which may be tightened upon the bar by a movement of the operator's wrench upon the head of the clamping screw *H*. The squared projection upon which the crank wrench is shown in the picture is the end of a pinion shaft by means of which the operater may move the main bar by hand in either direction to any desired position, first loosening the clamping collar *G*. All wrench-operated parts of the machine are fitted by the one crank wrench.

Fastened to the front of the carriage at *P* and held thereto by the three large hand-operated clamping screws to be seen under the carriage is a bar about 12 in. long, the inner profile of which is an exact replica of that of the piece to be ground. This piece is called the master bar and is produced by toolroom methods, for upon its

accuracy depends the accuracy of the product. The machine has no control over *relative* diameters. Actual diameter of the work as a whole is completely under control of the operator through the cross-feed screw and sizing mechanism, but, if one diameter upon a stepped piece is too large or too small in relation to other diameters upon the same piece, the fault is in the master bar and must be corrected there. (*American Machinist*, vol. 54, no. 8, Feb. 24, 1921, pp. 305–308, 9 figs., *d*)

POWER PLANTS

Non-Condensing Turbine Plant of the Western Felt Works. In felt works there is a considerable demand for steam for drying and heating, and when the company (located in Chicago) installed in the early part of 1920 two turbo-generators they made them non-condensing in order to satisfy the large and continuous demand for exhaust steam.

The two turbo-generators have capacities of 500 and 300 kw., respectively, at 80 per cent power factor, and supply three-phase 60-cycle cycle current at 220 volts.

As practically all the exhaust steam is utilized, the water rates are not of great importance, but the guarantees are as follows when the machines are supplied with steam at 150 lb. pressure and 100 deg. superheat: For the 500-kw. machine at one-half load, 40 lb., and for the full load of 500 kw., 37.1 lb. per kw-hr. For the smaller machine the water rates are 53.9, 45.1 and 40.9 lb. per kw-hr., respectively. (*Power*, vol. 53, no. 8, Feb. 22, 1921, pp. 294–297, 4 figs., *d*)

New Hammermill Plant. Description of a plant operated in conjunction with the paper mill of the Hammermill Company, Erie, Pa., the most interesting feature of which is that it employs superheated steam for both prime-mover operation and manufacturing processes.

There are four 509-hp. water-tube boilers, each built for 250 lb. gage pressure, though ordinarily operated at 235 lb. gage and equipped with superheaters for raising the temperature of the steam 150 deg. fahr. above that corresponding to the pressure. Whenever possible these units are worked at 175 per cent of their rated capacity, which has been found to be the loading providing the greatest overall economy.

In addition to superheated steam, saturated steam is also available for the operation of such auxiliaries as the stoker engines, pumps, etc. (*Power Plant Engineering*, vol. 25, no. 4, Feb. 15, 1921, pp. 201–204, 6 figs., *d*)

PUMPS

Formulas Dealing with Valves of Reciprocating Pumps

Investigation of Automatic Pump Valves and Their Influence on the Operation of Pumping Machinery. Ludwig Krauss, D.E. Notwithstanding the very extensive use of reciprocating pumps, no sufficient information is available for such design of valves as will prevent their knocking. It is with this in view that an investigation on the suction and pressure valves in pumps was recently undertaken in the machinery laboratory of the Technical High School in Dresden.

The experimental pump took water either from a suction tank 9.5 m. (30.2 ft.) below the pump or from a well of a turbine installation.

The construction of the pump shown in the original article does not represent anything unusual. It is a double-acting pump with an output of 120 cu. m. (4237 cu. ft.) per hr. at 75 r.p.m. and at a pressure head of 10 atmos. For test purposes it was rebuilt into a single-acting pump and so constructed that it was possible to change the spring arrangement on the valve while the pump was running and that the same amount of water could be handled at several speeds of the pump. This latter was achieved by using on the same piston rod pistons having diameters of 90, 118 and 140 mm. (3.54, 4.36, 7.5 in.).

Figs. 13 and 14 show the various valve-lift diagrams for the suction and pressure valve in triple magnification. The indicator drums were running at a uniform speed and as their speed of rotation could be measured, the velocities of valve lifts could be easily derived from the diagrams. Two other figures in the original article give the pressure-difference diagrams for the pressure valve and suction valve.

As regards the planning of the test, it was decided to determine the influence of such factors as agree in practice on the play of the valve, on the degree of delivery through the valve and on the indicated efficiency. The factors which were considered to be variable within wide limits were the delivery head, the volume of water handled and the load on the valve.

To determine the play in the valve, suction heads of 2, 4 and 6 mm. of water were employed and water admitted under a pressure of 2.5 atmos.; furthermore, the pressure head could be raised as high as 10 atmos.

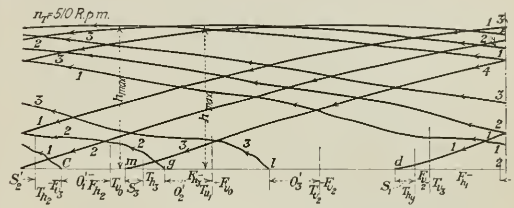

Fig. 13 Pressure-Valve Lift Diagram

To determine the delivery, the volume of water handled was varied from 10 to 115 cu. m. (353 to 4060 cu. ft.) per hr. by varying the speed of rotation of the pump from 25 to 150 r.p.m. and then using four different pistons with areas of from 47.12 to 185.85 sq. cm. (7.2 to 28.6 sq. in.).

The data of the tests are presented in numerical form and also as curves.

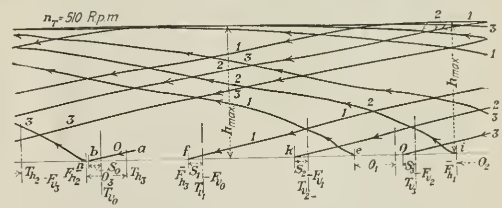

Fig. 14 Suction-Valve Lift Diagram

The following represents the main general conclusions arrived at from the results of the tests:

Opening and Closing of the Valves. In general, it may be said that the valves have a tendency both to close and to open late. A valve does not open immediately after the closing of the opposite valve, but there is a lag which is greater in proportion to values of the suction head, the suction valve load and the speed of rotation.

Knock at Opening of the Pressure Valve. The strength of this knock is determined by the timing of the opening of the pressure valve and also by the delay in the closing of the suction valve. On the other hand, it is but little affected by the increase in load of the pressure valve and by increase in the pressure head as long as the operation of the pump is kept within normal limits. The knock is decreased by the unloading of the suction valve, whereby the suction capacity of the pump is increased, and by lack of tightness of the pressure valve. This is explained by the fact that after the closing of the suction valve a water-free space is formed under the pressure valve. As a result the water reaches the lower face of the pressure valve only a certain time after the reversal in the direction of the stroke, and does it with a blow, which, in the case of a pump running low, has a dull sound, and a poorly running pump a loud, hard, metallic sound.

Knock at Closing of the Pressure Valve. This knock is the louder the smaller the initial compression of the spring and the greater the maximum valve lift, but even with a large initial compression

of the spring and a slight valve lift it can be heard. It has not been found possible to locate a clearly defined point at which the pressure valve closes without a blow. Because of this, it is not possible to test the correctness of the Klein law, in accordance with which the product of the speed of rotation per unit of time times the maximum valve lift is a constant at the same valve load at the point where the closing of the valve takes place free of knock.

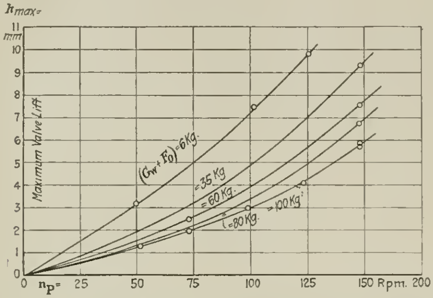

Fig. 15 Variation of Maximum Valve Lift with Speed of the Pump and Load on the Valve

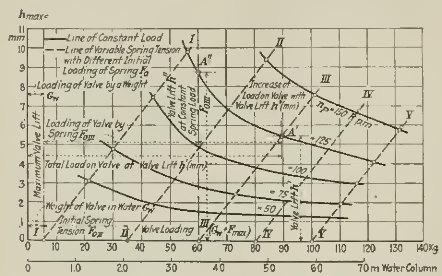

Fig. 16 Variation of Maximum Valve Lift with Sprino Tension on the Valve and Speed of the Pump

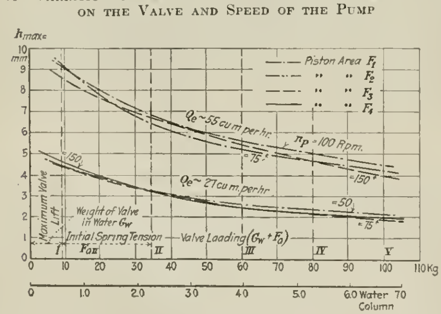

Fig. 17 Variation of Maximum Valve Lift with Load on the Valve and Volume of Water Handled per Unit of Time

The knock at the closing of the suction valve was under the same conditions and a normal valve clearance always found lighter than the knock in the closing of a pressure valve of the same construction, a fact which could be determined both by listening and from the measurement of the velocity of the valve closing.

Velocity (v_s) *of Valve Closing.* This was determined from the curves of valve lift and it was found that at quiet running v_s = 80 mm. (3.14 in.) per sec.; at ordinary running v_s = 100 to 120 mm. (3.9 to 4.7 in.) and at noisy running v_s is greater than 130 mm. (5.1 in.) per sec. These values can of course vary with individual valves.

The maximum lift h_{max} is a function of the volume of water handled, the load on the valve, and the dimensions and design of the valve, but is entirely independent of the pressure head employed.

Apart from the violent oscillations in the suction valve when the suction of the pump is poor, it is usual to make the maximum lift of both suction and pressure valves the same with the same spring load. If sufficient experimental information is available to determine the value of the coefficient of justification μ_P, then the maximum valve lift may be calculated with a precision sufficient for practical purposes from—

$$h_{max} = \frac{Q\pi}{\mu_P l \sqrt{2g \dfrac{P_{max}}{f\gamma}}} \qquad [1]$$

where Q is the volume of water handled in cubic meters per second, l the length of the clearance in meters, P the load on the valve in kilograms, and f the free valve-seat area expressed in square meters.

It is impossible to express in a general manner the maximum value for h_{max} for any given case, but it can be determined by experiment and in the original investigation a table is given. This table is not reproduced in the article from which this abstract is made. By increasing the load on a valve the lift may be decreased simultaneously with the increase of the valve resistance. This can safely be done in the case of the pressure valve but not with the suction valve because it might produce in the suction valve a loud knock at the instant of opening the pressure valve, and the irregular operation of the valve.

In this connection the curves in Figs. 15, 16 and 17 are of interest, of which the first gives the values for the maximum valve lift for a given speed of the pump in revolutions per minute and for valve loads varying from 6 to 100 kg., all other conditions being the same. The next figure gives the maximum valve lift at a given load for speeds of the pump varying from 50 to 150 r.p.m., and finally the last of the three gives the maximum valve lift at a given load for volumes of water equal to 27 and 55 cu. m. per hr., respectively. From this last figure it would appear that, all other conditions being equal, the valve lift is mainly determined by the volume of water handled.

The second part of the article deals with various individual results obtained from the tests and may be abstracted in an early issue if space is available. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 5, Jan. 29, 1921, pp. 116–122, 23 figs., *etA*)

RAILWAY ENGINEERING (See Machine Shop)

SHIPBUILDING (See also Machine Shop)

Reaction Propulsion of Ships—The Hotchkiss System

Hydraulic Propulsion of Ships. Hydraulic or reaction propulsion of vessels, whether air or water craft, is an old idea and has been tried many times, though thus far never successfully.

Reaction propulsion has certain advantages, the first being the relative simplicity of the propulsive equipment and elimination of the propellor with its appendages, which means not only fewer parts but absence of a rapidly rotating element outside of the ship hull subject to fouling and breakage. The elimination of the propeller leads also to the reduction of vibration. To this is added the ease with which the motion of a hydraulically propelled boat may be reversed simply by deflecting the stream forward without even reversing the prime mover. This adds to the ease with which the vessel can be maneuvered and makes it possible to eliminate the rudder, another element outside of the ship hull subject to all kinds of untoward accidents.

Finally, the thrust developed by the discharge of the stream of water is independent of the depth at which the stream is discharged, while the depth of immersion of a screw propeller greatly affects the thrust. From these considerations it follows that racing cannot occur in a hydraulically propelled boat. In addition, the depth of water in which the ship operates efficiently is limited solely by the draft of the hull and not by the draft required for the efficient working of the propeller.

Among the disadvantages cited against hydraulic propellers the chief is lack of efficiency. Various causes have contributed to the lack of efficiency shown by the systems tried in the past. If we regard hydraulic propulsion as consisting simply of the use of an internal propeller, it is obvious in the first place that loss will occur

by virtue of the fact that the stream of water has to be brought to and discharged from the propeller through pipes and passages or orifices of some description. The frictional losses in such passages have no counterpart in the external propeller, for in this case the water is drawn from and discharged into the immediately surrounding fluid. Again, in reaching and leaving the internal propeller, the water may in its flow be called upon to change its direction of movement to a considerable extent, with a consequent considerable loss of energy. The water passages, too, may change in cross-sectional area, and as a result loss will arise by the conversion of pressure into velocity and velocity into pressure.

Lately, however, several reaction propulsion systems have been tried out. The Mélot system as applied to aircraft was described in Mechanical Engineering, April 1920, p. 234. The Hotchkiss and the Gill systems have recently been tried out for water craft.

The Hotchkiss system was tried on a weldless steel launch measuring 24 ft. in length overall and 6 ft. 3 in. in beam, with a draft of 1 ft. 5 in. on a displacement of two tons. The machinery propelling the vessel consisted of an 8-b.hp. motor coupled through reduction bevel gearing to two Hotchkiss pumps.

The general principle of the Hotchkiss system is illustrated in the diagram of one of the pumps given in Fig. 18. The pump consists of a four-bladed impeller rotating within a cylindrical casing, in which are formed three openings, namely, one in the lower half of each vertical side, and one in the lower portion of the periphery. In the diagram the two strips of the casing separating these three holes are represented as having been cut out, so that the holes really form but one hole. It will be convenient, however, to regard them as being in three. The casing is considerably wider than the impeller blades, so that between the edges of the blades and the vertical walls of the casing there is a passage on each side of considerable area.

In the diagram the movement of the boat is supposed to be toward the left. The impeller is driven in the direction of the arrow shown against it, and creates a vortex inside the casing. The water is drawn into the casing in two streams through the two side holes. Inside the casing these two streams converge, and finally become one, which, passing centrally between the two entering branches,

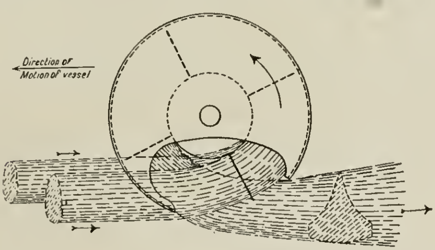

Fig. 18 Diagram of the Hotchkiss Pump Used for Reaction Propulsion of Ships

is discharged sternward. The peculiar section which, according to Mr. Hotchkiss, the discharge stream assumes will be noted. It enables the discharge stream to pass between the entering streams without touching them, while at the same time it fills up nearly all the vacant space between them, on the assumption that the entering streams are circular or oval in section.

The essential feature of the Hotchkiss system is thus the creation of a vortex that travels along with the vessel. The water is drawn directly into the vortex without the intermediation of pipes or conduits of any description, and, therefore, frictional losses are practically avoided. The relative momentum of the incoming water, it is claimed, is not lost, but forms part of the momentum of the discharge stream.

The system is still in the experimental stages and no reliable data as to efficiency are available. It is stated, however, that the boat developed 5.6 knots (9.46 ft. per sec.) with the engine running at 950 revolutions and developing $7^3/_4$ b.hp. The speed of discharge of the stream from the pumps is calculated by Mr. Hotchkiss to be 16.4 ft. per sec. Calling these two speeds v and V, respectively, the slip is $(V - v)/V$, or 42.3 per cent. The jet efficiency, in accordance with the usual formula, is $2v/(V + v)$, or 73 per cent. Mr. Hotchkiss takes the efficiency of the pumps at 90 per cent, so that the propulsive efficiency comes out at 65.7 per cent. Taking the efficiency of the engine at 75 per cent, the overall efficiency is thus 49.3 per cent. Such an efficiency, it is stated, would not be considered bad in a similar vessel propelled by screw.

These figures, however, have not been checked by any reliable outside authority and are cited merely because of the revival of interest in reaction propulsion. (*The Engineer*, vol. 131, no. 3398, Feb. 11, 1921, pp. 140–142, 3 figs., *d*)

SPECIAL MACHINERY

Novel Rotor-Balancing Machine

The Martin Rotor-Balancing Machine. Description of a simple device for balancing rotary bodies—of particular interest because of its great sensitiveness. This latter is such that, for example, when balancing a rotor of 10,000 kg., a variation of 1 kg-cm. can be easily discovered by sliding a weight of 1 kg. along the beam. This corresponds to a deviation of the center of gravity of the rotor in a horizontal direction off the axis of 0.005 mm., or approximately one fifty-thousandth of an inch.

The same result is expressed in a different way, as follows: When balancing a 10-ton Zoelly rotor of 6 ft. diameter, an overweight of as little as 10 grams (one-third ounce) on its circumference, or one-millionth part of the rotor's weight, can be readily detected.

Furthermore, the apparatus indicates the correct plane in which this overweight lies and in which its moment acts. These results

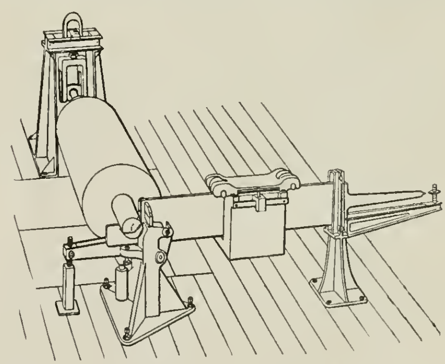

Fig. 19 Martin Rotor-Balancing Machine

are obtained without rotation, as it is merely necessary to turn the body to six or eight fixed positions and when actually balancing no rotation takes place. Because of this the method is not affected by the inertia of the body and the angle of lag cannot affect the results.

The machine (Fig. 19) consists of two main portions arranged to support the shaft of the rotor to be balanced. At one end the shaft is hung in a universally jointed stirrup and at the other in a bearing which is mounted on the short arm of a steelyard lever.

Having placed the rotor to be balanced in the bearings, the main weight of the steelyard is adjusted so as to bring the arm into equilibrium. The rotor is then turned a few degrees and the arm again adjusted by moving the jockey weight, this adjustment being recorded. The rotor is then turned through another section, and the necessary adjustment again made by means of the jockey weight, and so the process is continued for a complete revolution. The results are plotted to a horizontal base, and the sine curve obtained shows a maximum and minimum which indicate the points at which the center of gravity is farthest from, and nearest to, the supporting point of the balance. By multiplying the jockey weight by its displacement, a moment is derived from which the eccentricity of the center of gravity and the necessary correc-

tion are obtained. Table 4 gives some actual results that have been obtained with a large balance.

On all built-up turbines, such as the Zoelly and Curtis types, first the shaft and then each disk put on is successively balanced; the final balance obtained will then be without any disturbing couple, and many times more accurate than any result obtainable by other methods. In a drum-type turbine, such as the Parsons rotor, the overweight is taken out partly at each end in relation to the position of the center of gravity, the sum of this moment being equal to the total moment of overweight. Reduction-gear wheels can also be balanced by this machine, and for bodies which are of relatively large radial and small axial dimensions, a mandrel (in itself balanced) to take such parts can be used on the machine. The machine could also be used for standardizing rotary parts. (*The Electrical Review*, vol. 88, no. 2253, Jan. 28, 1921, pp. 101–102, 4 figs., *d*)

TABLE 4 RESULTS OBTAINED WITH A LARGE-SIZE MARTIN ROTOR-BALANCING MACHINE

Turbine rotors balanced:	Weight, kg.	Out-of-balance moment found, kg-cm.	Weight removed (dependent on the radius), kg.	Corresponding correction of rotor's c. of g., mm.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

Professional Engineering Service Announcements

One hundred and twenty engineers and engineering concerns are now represented in the Professional Engineering Service Section of Mechanical Engineering (see pp. 106–112 of Advertising Section). This is a substantial increase over the number in the March issue, and fifty per cent more than in February. Since the addition of a classified index to this section its usefulness to those in need of specialized engineering assistance has greatly increased; and users of cards are benefited accordingly.

The classified index comprises approximately 150 headings, under which the users of professional cards are listed according to the lines in which they specialize. The card announcements appear on pages directly following, so that after a reader has selected one or more names from the classified index, he can easily find the corresponding cards giving more detailed information regarding the services offered.

With the increase in size and completeness of the Professional Service Section it becomes more and more a clearing house for engineering service by experienced engineers who have specialized in different fields of activity.

A new alloy patented in France and adapted specially to the manufacture of valves for internal-combustion engines, is composed of nickel, about 67 per cent; iron, 1 to 5 per cent; and copper, 28 to 32 per cent. It is said to have the same coefficient of expansion as cast iron, to offer great resistance to the destructive action of the high temperatures to which the valves are subjected, and to be insensible to corrosion by the hot combustion gases.

LOCOMOTIVES AND LOCOMOTIVE TERMINALS

(*Continued from page 258*)

The trend in locomotive-terminal development is undoubtedly toward facilities for executing a greater and increasing variety of heavy repairs. In fact it is not beyond the range of possibilities to comprehend a development in locomotive terminals that will supersede many of the functions now belonging to the central erecting shop.

B. P. Phelps[1]. One of the first considerations of a new terminal should be that of ground enough to permit an expansion of each unit at least 100 per cent over the original installations. Terminals in cities should be located out far enough from the region of expensive real estate to secure enough land at a reasonable price to allow for such a ratio of expansion; unless there are peculiar operating conditions which prevent. In a developing country, the demand on terminal facilities is doubled in a period of ten to fifteen years. Therefore such layouts as shown by the author,[2] while conveniently arranged for the present needs, may soon be outgrown.

As a further provision for expansion, when the initial installation of a roundhouse includes less than a complete circle, no permanent buildings or tracks should be placed within the circle to be in the way of completing the roundhouse.

The writer would suggest that in general the storehouse should be next to the roundhouse and centrally located with reference to the machine shop, blacksmith shop, and car department. Efficient means should be provided for handling stores from cars to platform and building and also to the several shops.

The back shop (locomotive repair shop) is most convenient if located at the back of the roundhouse and about the center of the circumference of the outer wall. It would appear that a back shop located as in Fig. 1[2] would be inconvenient for machinists working on locomotives to get machine work done, especially men in the north roundhouse.

The blacksmith shop should be handy to both the roundhouse and back shop as the work done in this shop is about equally divided between running or roundhouse repairs and back-shop repairs.

On Western railroads running through districts of bad water, flue-repairing facilities demand much consideration.

In one paragraph Mr. Rink mentions the use of blow-off water from locomotives for filling boilers. Numerous tests made in bad water districts have shown that blow-off water contains one hundred and fifty to five hundred grains of soluble salts per gallon or the equivalent of about a barrel of salt to a locomotive boiler full of water. These salts do not settle but remain in solution at ordinary temperatures. Concentration of these salts in a boiler will cause the water to "prime" or "foam," which is objectionable. Except in emergency cases it is far preferable to fill boilers with fresh water.

G. W. Rink, in his closure, spoke of the chart mentioned in the discussion by Wm. Elmer, on which was recorded the frequency with which a locomotive found its way into the shop and which indicated when a locomotive was ready to go back to the main shop for general repairs. This, he said, brought out the fact that most main shops were inadequate and that they could not keep up with the necessary repairs. Therefore he thought the roundhouses ought to be helped as much as possible by providing them with as many facilities as could be afforded.

He said that he preferred jib to overhead cranes for roundhouses as the overhead crane was not capable of serving several gangs of men working on different jobs.

He pointed out that the loss of time in getting a locomotive into and out of a roundhouse was responsible for many makeshift repairs, as not enough time remained if the motive power were being used intensively. The train and engine must go whether the repair is made or not, unless the case is serious enough to warrant taking the locomotive out of service.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Apparatus and Instruments A3-21. Viscosimeter. Use of MacMichael Viscosimeter in petroleum products is the subject of Report 2201 of the Bureau of Mines, by W. H. Herschel and E. W. Dean. The MacMichael viscosimeter is of a torsional form and has been described by W. H. Herschel in the *Journal of Industrial and Engineering Chemistry*, vol. 12, 1920, pp. 282–286. It takes a shorter time for a determination than the Saybolt viscosimeter and gives moderately accurate results with oils that are not perfectly homogeneous. The instrument requires careful attention to manipulate it. This viscosimeter consists of a rotary oil cup which is motor-driven and a torsional pendulum suspended above the cup by a piano wire. The pendulum consists of a tube enclosing the suspension wire and carrying a disk at its lower end. The deflection of the suspension is converted into absolute viscosity. The report gives the relation between kinematic viscosities and Saybolt viscosities, as well as the method of translating readings of the MacMichael viscosimeter into absolute viscosities. Bureau of Mines, Washington, D. C. Address Director.

Cement and Other Building Materials A5–21. Repeated Stresses in Concrete Beams. The Bureau of Standards has just issued Technologic Paper 182 which is for sale by the Superintendent of Documents, Washington, D. C., at 15 cents per copy. It describes the results of tests made on concrete beams 4 in. by 6 in. in cross-section, using a span of 8 ft. The beams were reinforced both top and bottom. The load was applied at two points each 6 in. from the center of the span, and at the rate of 17 cycles per minute, each cycle including an upward and downward application of load. By means of a system of levers a dead weight used for load was multiplied ten times at the beam. The loading mechanism was driven through a walking beam. Four beams were tested to failure and a fifth beam was loaded through two million cycles, although the beam did not appear to approach failure.

The four beams on which the tests were completed failed by tension in the steel. The beam showing the highest stress withstood the smallest number of repetitions. The largest number of repetitions was so small that failure in the steel would not have been expected as the observed stresses were low. Other factors than the intensity of the tensile and compressive stresses must have caused the early tension failure.

All tension failures in reinforcing bars occurred at sections where large cracks extended entirely across the section of the beam. It is possible that in some cases the bending at these cracks was sufficient to make the bending of the bar an important factor in causing failure. The slipping of the bars and the resulting opening of the cracks must have increased this action. The quality of steel used in the reinforcement was poor, although this does not account for the small number of repetitions. After 7000 cycles the slip in the end of the bar in one beam was less than 0.001 in. This is less than the amount taken as the criterion for safe conditions of bond. After 400,000 cycles the slip in the bar was so great that failure by slipping seemed imminent. This investigation was undertaken for the Emergency Fleet Corporation in connection with the development of concrete ships. Bureau of Standards, Washington, D. C. Address Director.

Cement and Other Building Materials A6–21. Tannic Acid in Concrete. The effect of tannic acid on the strength of concrete is the subject of Bulletin No. 7, by Prof. Duff A. Abrams, of the Structural Materials Research Laboratory, Lewis Institute. The Bulletin is a result of four years' investigation to determine the effect of organic impurities in sands. Natural sands could not be used for a quantitative analysis and so aggregates were prepared in which known quantities of organic impurities were present by the addition of tannic acid. The amount of tannic acid varied up to 0.40 per cent of the aggregate by weight. Compression tests were made on 3-in. by 6-in. concrete cylinders with various mixes ranging from 1 : 5 to 1 : 2. The size of the aggregate varied from a fine sand to $^3/_4$ in. Tests were made at ages of 7 days, 28 days, 3 months, 1 year and 2 years, the series including 2000 tests. The following conclusions were derived:

The results were comparable with the effects produced with natural sands containing organic matter.

All percentages of tannic acid in all mixes and ages reduced the strength of the concrete.

Less than 0.1 per cent of tannic acid reduced the strength of the concrete to one-half its normal value.

The lean mixtures are more affected than rich mixtures.

Mixtures from finer aggregates are less affected than those from coarser aggregates.

The reduction in the strength of concrete is a function of the concentration of the tannic acid in the mixing water.

Wetter consistencies are less affected than drier consistencies.

The strength falls off rapidly for small percentages of tannic acid at the beginning of the increase and less rapidly as higher percentages are reached.

The 7- and 28-day strengths are reduced by a greater amount by tannic acid than the strengths at ages of 1 and 2 years.

Some 1 : 5 mixes disintegrated before the time of test.

When higher percentages of tannic acid were used with finer sands 1 : 7 mixes were destroyed in removing them from the mold.

Care should be taken to remove surface loam from concrete sands. Loam can be generally removed by washing.

Address Prof. Duff A. Abrams, Lewis Institute, Chicago, Ill.

Chemistry, Mineralogical and Geological A1–21. Potash Production. See *T. Poole Maynard E1–21.*

Fuels, Gas, Tar and Coke A5–21. Stenches for Determining Leakage. Technical Paper 267, by S. H. Katz and V. C. Allison, on Stenches for Detecting Leakage of Blue Gas and Natural Gas, has recently appeared from the Bureau of Mines. The report contains a number of tables, two illustrations and extends over 22 pages. It deals with the properties, intensities, quantities and cost of production of stenches and describes the method of impregnation. Bureau of Mines, Washington, D. C. Address Director.

Fuels, Gas, Tar and Coke A6–21. Sulphur Distribution in Carbonization. A study made by Prof. C. C. Thomas and U. O. Hutton, of Johns Hopkins University, Baltimore, Md., in collaboration with the Bureau of Mines was intended to determine the distribution of sulphur in carbonization of coal in gas retorts. The experiments were of three classes: first, to determine the sulphur production in gas with uniform charges of 300 lb. at different temperatures, a second set to study the effect of varying the size of the charge, and a third set to determine the effect of spraying the coal with milk of lime before charging. The article describing this research is given in the *Gas Age* for Feb. 10, 1921, and gives curves showing the rate of gas production, the effect of temperature on sulphureted hydrogen and sulphur variation, the variation of organic sulphur with the charge, the variation of carbon disulphide and organic sulphur, the effect of carbon disulphide, the effect of spraying the coal with lime, the effect of the size of the charge and the variation of the sulphur. The experiments show that the sulphur in the gas may be reduced by low temperatures, the use of larger charges, and the spraying of milk of lime over the coal.

Mechanics, General A1–21. Repeated Stresses in Concrete Beams. See *Cement and Other Building Materials A5–21.*

Metallurgy and Metallography A9–21. Metal Arc Welds. See *Welding A1–21.*

Petroleum, Asphalt and Wood Products A2–21. Properties of Crude Oils. The Bureau of Mines has issued report No. 2202 on the Properties of Typical Crude Oils from the Eastern Producing Field of the United States, by E. W. Dean. Bureau of Mines, Washington, D. C. Address Director.

Petroleum, Asphalt and Wood Products A3–21. Lighter Hydrocarbons. The Bureau of Mines has recently issued Bulletin 162, by J. N. Wadsworth, on the Removal of Lighter Hydrocarbons from Petroleum by Continuous Distillation. This bulletin contains drawings and detailed descriptions of apparatus and equipment. In addition its 162 pages comprise 31 tables showing various data from the plants, and 49 plates of drawings of apparatus and 45 figures. Bureau of Mines, Washington, D. C. Address Director.

Properties of Engineering Materials A1–21. Repeated Stresses in Concrete Beams. See *Cement and Other Building Materials A5–21.*

Properties of Engineering Materials A2–21. Standard Samples. Standard samples of materials of known composition are issued by the Bureau of Standards at different prices. A new standard cast bronze has been placed in stock and renewals of certain cast irons, bessemer steel and other materials have been added. Bureau of Standards, Washington, D. C. Address Director.

Welding A1–21. Arc Metal Welds. The properties of arc metals and arc welds as determined by tests form the subject of a paper printed in *Power*, Feb. 15, 1921, by O. H. Eschholz, of the Westinghouse Electric & Manufacturing Company. The paper shows the different ways in which the metal of the weld was applied and tested, including the form of specimens used and the appearance of broken specimens under

tension, compression, bending and impact. The article gives microphotographs. The investigation shows that properties of metals deposited from bare electrodes are dependent on the direction of stress relative to the direction of depositing the metal in the weld and also on the procedure during deposition. The greatest resistance occurs when the load is applied parallel to the direction of layer deposition and least when applied perpendicular to the layers. The strength of the weld in mild-steel plates was almost as great as the strength of the plate with high-carbon steel, which amounted to 70 per cent of the strength of the plate. The test showed that the strength of the weld with the same metal used for the arc pencil depends on the surfaces welded together, the weld absorbing from the parent metal certain materials which give it additional strength.

The presence of small quantities of iron oxide and nitride does not appear to greatly effect the properties of the metal when stressed by static load, although under repeated load and in impact testing these substances affect the strength. The field of bare alloy electrodes and covered electrodes shows development possibilities.

Wood Products A2-21. Smoke Making for Testing Circulation in Kilns. Technical Notes 127 of the Forest Products Laboratory gives a device for making smoke to be used for testing circulation in kilns. This can be used for testing circulation in any space. It consists of two bottles held in a frame, one filled with ammonia, the other with hydrochloric acid. Air is blown into the hydrochloric acid bottle through a tube in the cork above the level of the acid. Another bent tube leads from this cork into the open end of the ammonia bottle. This apparatus may be carried on a handle without danger of fire. Forest Products Laboratory, Madison, Wis. Address Director.

Wood Products A3-21. Strength of Wooden Boxes. Moisture content of wood greatly affects strength of the box. Within a week of manufacture a box made from green lumber is greatly reduced in strength. As the wood dries the nails lose their grip. After one year boxes from green lumber proved to be 1/6 as strong as similar boxes tested at time of manufacture. Forest Products Laboratory, Madison, Wis. Address Director.

Wood Products A4-21. Plywood. Wood has a tensile strength in the direction parallel to the grain which is 20 times higher than the strength perpendicular to the grain. The shearing strength across the grain is much greater than that parallel to the grain. Wood shrinks a greater amount across the grain than with the grain. For the above reasons plywood is used to make a stronger product for the same weight. The desire is to obtain material which has an equality of properties in two directions. It has been shown that an increase in the number of plies results in the decrease of the tensile and bending strength, parallel to the grain but increases these at right angles to the grain. Hence when the strength should be equal in two directions a great number of plies should be employed. A large number of plies increases the resistance to splitting from screws and bolts. U. S. Forest Products Laboratory, Madison, Wis. Address Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Apparatus and Instruments B2-21. Micrometers. Micrometers for Electric Purposes. University of Pennsylvania, Department of Mechanical Engineering, Philadelphia, Pa. Address Prof. J. J. Morris.

Electric Power B1-21. Sky-Line Cables. A method for calculating sky-line cables is the subject of a bulletin in preparation by S. H. Anderson, of the Engineering Experiment Station, University of Washington, Seattle, Wash.

Electric Power B2-21. Current Suppression. Current suppression by means of parallel resonance is the subject of a bulletin in preparation by H. G. Cordes, of the Engineering Experiment Station, University of Washington, Seattle, Wash.

Foundry Equipment, Materials and Processes B1-21. Facing Sands. Experiments on Facing Sands for Molds to Reduce Chill and Eliminate Searching Influence of the Metal. University of Pennsylvania, Department of Mechanical Engineering, Philadelphia, Pa. Address Prof. J. J. Morris.

Heat B1-21. Heat Transfer. A study is being made by Mr. Christian Gierloff of Trondhjem, Norway, on the heat losses through building materials similar to the work which is being done at the University of Saskatchewan by the construction of small cubic houses of different wall construction which are heated by electric means.

Hydraulics B1-21. Hydraulic Formulas. The rationalizing of hydraulic formulas is the subject of a bulletin by C. W. Harris, of the Engineering Experiment Station, University of Washington, Seattle, Wash.

Machine Design B1-21. Victrola Device. Repeating Device for Victrola Records. University of Pennsylvania, Department of Mechanical Engineering, Philadelphia, Pa. Address Prof. J. J. Morris.

Machine Tools B2-21. Multiple Die. Multiple Die for Thread Cutting. University of Pennsylvania, Department of Mechanical Engineering, Philadelphia, Pa. Address Prof. J. J. Morris.

Welding B1-21. Electric Welding is the subject of a bulletin in preparation by Addison G. Bissell, of the Engineering Experiment Station' University of Washington, Seattle, Wash.

Wood Products B1-21. Motor-Truck Logging is the subject of a bulletin in preparation by F. Malcolm Knapp, of the University of Washington, Seattle, Wash.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

Heat C1-21. Superheated Steam on Cast Iron. See *Metallurgy and Metallography C1-21.*

Metallurgy and Metallography C1-21. Cast Iron with Superheated Steam. It is desired to obtain references and results on the subject of the action of superheated steam on cast iron. Address R. Z. Hopkins, Hudson Motor Car Company, Detroit, Mich.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

T. Poole Maynard E1-21. L. E. Mallory, V. R. Waite and J. T. Nash are associated with Dr. T. Poole Maynard in geological and industrial engineering at Atlanta, Ga. Mr. Mallory is devoting his time to mechanical and chemical engineering, Mr. Waite to mining, Mr. Nash to civil and drainage engineering and Dr. Maynard to geology. The recent work of these gentlemen has been the investigation of methods of producing potash from Georgia potash slates. After laboratory investigations a plant was put into operation resulting in the production of 1000 tons of potash by treatment in a rotary kiln, resulting in the recovery of about 98 per cent potash and definitely establishing the commercial feasibility of this process.

Other investigations are being carried on for the application of American clays in manufacturing industries. By the application of simple technical control, uniform products can be prepared.

This group of engineers is prepared to make geological investigations and to care for mining and chemical operations and plants and to furnish advice to manufacturers.

Address T. Poole Maynard, Ph.D., Atlanta, Ga.

University of Washington E1-21. The Engineering Experiment Station of the University of Washington at Seattle, Wash. has issued to date the following 11 bulletins, which may be purchased at various prices varying from 25 cents to 80 cents on application to the Director of the Experiment Station:

1 Creosoted Wood-Stave Pipe and Its Effects upon Water
2 Ore Resources of the Northwest
3 Industrial Survey of Seattle
4 Mining and Metalliferous Mineral Resources of Washington
5 Electrometallurgical and Electrochemical Industry of Washington
6 Ornamental Concrete Lamp Posts
7 Multiplex Radio Telegraphy and Telephony
8 Voltage Wave Analysis
9 Coking Industry of the Pacific Northwest
10 Compressed Spruce Pulleys
11 Linear-Sinoidal Oscillations.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file in the offices of the Society.

Cement and Other Building Materials F1-21. The Effect of Organic Impurities on Concrete. A bibliography of one page giving 17 references to the effect of organic impurities when mixed with concrete. Address A.S.M.E., 29 West 39th St., New York.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

The Engineer Not a Good Mixer

TO THE EDITOR:

The engineer's training and duties, which call for sustained mental concentration, conspire to make him seem uninteresting or out of his element when not talking shop. Except in large cities, which support engineers' clubs and similar organizations, he finds himself more or less out of human touch even with his professional brethren. As a result of these circumstances the engineer is apt to develop a manner of reserve which not only is not wholesome but is a drag on his greater worth both to himself and to society.

How to counteract this manner and induce the spreading of a wider comradeship is a subject which may well deserve the earnest consideration of our organization. Anything that facilitates the spirit of fellowship and better understanding cannot fail, in the writer's estimation, to stimulate progressive thought and action in our ranks. OTTO H. L. WERNICKE.

Gull Point, Fla.

The Position of the Engineer in Industry

TO THE EDITOR:

Such addresses as those delivered recently to engineers by Mr. Hoover, Major Miller, and Mr. Gompers, have brought out clearly the fact that the position of the engineer in industry has really become a unique one. While enjoying the confidence of the owner of industry he has overcome some of the prejudices and gained the approval of organized labor. This recognition of the growing place of the engineer in industry by both the owner and the worker not only opens a wider field for him, but involves also a twofold responsibility.

Now that we are surrounded by changed conditions in the business world and with a definite reaction setting in against organized labor, how much of a modification will be found in the attitude of the engineering profession, and will the newly acquired responsibility fade into the background? Obviously the changed attitude of labor, prompted largely by the fear of discharge, while enabling the owner to obtain a greater per capita output and more favorable concessions, contains little of constructive value to the furtherance of real coöperation. Will not the times directly ahead of us offer fewer inducements and greater difficulties for these efforts to create a basis for real understanding?

The writer recalls about ten years ago when the efforts of the engineer to introduce scientific management into the industries were coming to the attention of the general public, that certain machinists' trade unions caused a cartoon to be circulated which was intended to arouse the worker against the efficiency movement in shops. The central figure in the picture was an extremely busy machine operator who frantically and literally spread himself between two machines. He was flanked on each side by an inquisitive time-study artist, while in large letters referring to the seat of his reasoning powers was the caption "solid ivory." While this same view may yet be had generally by workers, there is nevertheless ample evidence that the engineer's efforts have convinced many of the labor leaders of their value. But now with conditions tightening up there are many instances of cuts in the worker's earnings without due regard to the smaller drop in living costs. These circumstances are quite likely to cause the worker to feel that somehow the efforts of the engineer have made it possible for the employer to get more out of him and at a lower cost.

On the other hand, the employer has recently given evidence of opposition to the engineer's attempts in the cause of harmony The recent attack upon Mr. Hoover by a Chicago manufacturer's paper, condemning his conference with labor leaders, is a case in point. An article in the current number of a prominent industrial magazine shows one instance of the lack of appreciation of the efforts made to create shop councils and give employees a means of representation. These are clearly indications of what may be expected if the present industrial condition continues.

No one who is at all familiar with the facts can doubt the beneficial effects of the engineer in industry during the period of maximum demand just passed. But now with demand at a minimum, is the resulting clamor from both sides to deprive the engineer of the advantages already gained which would aid him in increasing the "field of common interest" referred to by Mr. Hoover? Surely it is possible to determine a definite attitude toward such matters as shop councils, employee education and representation and collective bargaining, all of which have a vital relaton to the establishment of a basis of understanding. Will it be frankness or secrecy, enlightenment or ignorance, mutual interest or suspicion and distrust, which will dominate our industries? On the outspoken opinion of the engineering profession and the attitude with which this question is met, much will depend.

It is of course recognized that there are many things to be settled in the proper development of rational industrial relations, but the basic facts can be recognized and adhered to, in spite of the reaction felt and expressed in many quarters. The training of the engineer and his habit of thought in basing judgment on facts and figures can be best put to use now when the extremists on both sides are attempting to undo a work of real constructive value. As one writer has expressed it, "They who have a big message for an anxious nation are the engineers and production experts, who are able to see that industry has a human as well as a material side."

GILBERT R. HAIGH.

Lansing, Mich.

Endorses Idea of Engineers' Official Directory

TO THE EDITOR:

I am of the opinion that an official biographical directory of the members of the four national engineering societies would supply a real need. I have often had to obtain information regarding the professional careers of various engineers with whom I was not personally acquainted, and have had much trouble and inconvenience in obtaining it. It occurs to me that some such publication as you suggest on page 30 of MECHANICAL ENGINEERING for March, prepared by the societies themselves, working in coöperation, might replace their year books once every five or ten years.

The last edition of Who's Who in America contains 23,000 names and is sold to subscribers for $6.50. Making allowance for duplicates, I suppose there would be less than 50,000 names in a Who's Who Among Engineers. With the edition twice as large as that for Who's Who in America, the total price, it seems to me, should not exceed $10, and might be materially less.

The societies already have a large amount of the necessary biographical information and competent editorial staffs to prepare it. If the matter is begun now, probably the first edition could not be issued before 1925. I should think that in that same year these societies could omit issuing their annual year books, the saving from which could be applied to this new publication. There would undoubtedly be a large sale from such a volume to libraries, advertisers and commercial interests.

I sincerely hope the project can be carried through, not only for the convenience to the members of the engineering profession, but also for the legitimate publicity that it would bring to the general public regarding the work and lives of engineers.

S. M. Woodward.

Iowa City, Iowa.

The Monotony of Repetitive Production Methods

To the Editor:

I do not believe that Dr. Moss's comment in the March issue of Mechanical Engineering on the monotony of repetitive produc ion methods is quite comprehensive enough. There are unquestionably operators, men who are past middle life, who welcome the monotony of repetitive work on account of the fact that they are sure they can perform these accustomed duties satisfactorily, and also on account of the tendency to resist any sort of change that is found among older men. Any shop foreman has had numbers of instances of this sort in his experience—men who have done one thing so long that, if put on something no harder but new, they go to pieces on the strange work. Lack of self-confidence holds many men of all ages and degrees of mentality to those things that they are sure of. It is not that they do not like variety, but they are afraid of it.

There is another type of men both young and old who are found to resist change. In this group might be included the heavy, unimaginative types, the nerveless, stolid immigrants, the Man-with-the-Hoe types, and the youths who frequently make good operatives but are incapable of further advancement. The fact of the matter is that under present production methods this type of man is entirely acceptable to employers. They are not uneasy or dissatisfied unless stirred up by some one whose business it is to do it. An ambitious, active-minded man if held down to monotonous work either gets out of it as soon as possible or frets over it, which means a dissatisfied workman, and this may mean all kinds of trouble.

If Dr. Moss desires to secure evidence of the fact that there are certain types of men who do not prefer monotony of work, let him go into the toolroom of his shop and ask each of the toolmakers—die sinkers excepted—if he would rather run a nut-tapping machine or a semi-automatic screw slotter at the same pay as he is receiving as a toolmaker. And I may be doing the die sinkers an injustice at that.

L. L. Thwing.

Columbus, Ohio.

Development of Power from Wave Action

To the Editor:

During the summer of 1919 while residing at Oswego, N. Y., the writer made frequent trips along the southern shore of Lake Ontario, where in many places the outcropping rock forms a series of ledges or shelves against which there is often rather vigorous wave action.

In favorable locations the water, after striking these rocks, would be thrown fifteen to twenty feet in the air. After watching this display on several occasions the writer conceived the idea that if the waves were allowed to enter a funnel-shaped vessel and brought to rest therein, a considerable pressure might be developed at the smaller end; and that this pressure, if means were afforded, might be used to discharge water against a considerable static head. At the particular point investigated the farm land extended down to the water's edge so that excellent use could be made of the water for irrigation. The idea in that case seemed such a practical one that a crude funnel was constructed out of some old sheet iron and anchored with stones. This gave surprisingly good results and seemed to indicate that a more elaborate structure might be justified. To make the scheme more practical, a check valve might be added in the pipe leading from the small end of the funnel and an elevated storage tank provided to receive the water if required. It was planned to construct an experimental wave pump and place it in operation the following summer, but in the meantime the writer moved from Oswego and the matter was dropped.

It was estimated that in two or three days out of each week sufficient wave action was developed to operate the pump, while it often went several weeks without rain. The writer has already considered the possibility of using such a pump to elevate a large quantity of water to a height of four or five feet and allowing this water to flow through a small hydraulic ram and lift a portion of itself to a height of 50 or 60 feet or possibly more. Its limited times of operation might be a serious disadvantage, but on the other hand it might be entirely practical in some cases. It would certainly be an interesting and inexpensive arrangement and the writer hopes that this account may be the means of encouraging some one to undertake the construction of such a wave pump.

Allen F. Sherzer.

Ann Arbor, Mich.

Calibration of Nozzles for the Measurement of Air Flowing into a Vacuum

To the Editor:

The tests summarized in Wm. L. De Baufre's paper on the Calibration of Nozzles for the Measurement of Air Flowing into a Vacuum, which appeared in the November issue of Mechanical Engineering, page 607, appear to the writer to be the most accurate air measurements ever made. He was surprised, however, after reading the description of the theory and elaborate care taken with the tests, to find such great variations in the "average percentage weight-flow efficiencies" as those given in Column 6 of Table 2. This great variation disappears if the "coefficient of discharge" instead of the "weight-flow efficiency" is worked out.

Applying the formula[1] $\Omega = 0.001042\ Q/d^2$, where Ω = coefficient of discharge, Q = capacity of the nozzle in lb. per hr. and d = diameter of the nozzle in inches, to the fourth column of Table 1, the following values are obtained for the coefficient of discharge for the 20 nozzles:

Nozzle	Values	Nozzle	Values	Nozzle	Values
1	0.971	8	0.9715	15	0.9712
2	0.971	9	0.9722	16	0.9712
3	0.972	10	0.971	17	0.891
4	0.9725	11	0.971	18	0.972
5	0.971	12	0.9715	19	0.971
6	0.9715	13	0.9715	20	0.9715
7	0.9725	14	0.9715		

The amazing consistency of these values, except in the case of nozzle No. 17, shows the excellence of Mr. De Baufre's experimental work.

John Hodgson.

Leighton Buzzard, England.

Requirements of an Industrial Appraisal

To the Editor:

We have read with interest Mr. James A. Brown's letter on Appraisal Principles Applied to Industrial Properties, which appeared in the March issue of Mechanical Engineering.

During a lengthy experience as industrial engineers and accountants we have often been shown appraisals, supposedly to assist us in our work. Without being unduly critical, we must confess we have been struck by the variety of opinions among appraisal engineers as to the values to be presented and the manner of presentation. Certainly, they cannot all be right. There must be one best form for maximum applied usefulness. Let us see if we can find it. (We speak particularly of industrial appraisals, having no intention at present of contributing to the controversies raging about the evaluation of public utilities.)

Mr. Brown states very succinctly eleven principal uses of appraisals, whether industrial or public utility, including: (1) Rate setting, (2) depreciation charges, (3) taxes, (4) insurance, and (5) financial arrangements. Let us add one more: (6) Burden distribution for manufacturing-cost determination.

Passing by, for the present, special appraisals for sale, stock issue, loans, etc., it may be interesting to many readers of Mechanical Engineering for us to recapitulate briefly the requirements which, according to our observation, an industrial appraisal should meet.

[1] Derived from Eq. 27 of Hodgson's paper on the Commercial Metering of Air, Gas and Steam, Proc. Inst. C. E., vol. cciv, part 2.

We have found that the chief need in most plants is for an appraisal which will tell the operator just where he is at: i.e., a descriptive detailing of each piece of real property and equipment, with its *origin, date, original cost in place, rate of depreciation and present condition.* The appraisal schedules should present all these, so that each item may later be transcribed on a card, thus initiating a flexible and permanent equipment record. A schedule should include only one class of equipment, as buildings, machines, shafting, etc., much as such items would be classified in the ledger accounts. A total replacement value for each schedule should be given. Moreover, each schedule should be paragraphed and subtotaled by manufacturing departments, buildings and floors.

Total values should be summarized in three ways: by schedules (or ledger accounts), by departments (building space being prorated among these) and by insurable and non-insurable values. The first two, of course, present invested capital; the last, replacement values.

Unless equipment is already numbered, a system of identifying numbers should be used and key drawings made, linking the items listed in the schedules with their location in the plant.

Now, an appraisal so detailed and so arranged, with all values based primarily upon original investment, supplemented by general replacement costs, will serve all the aforementioned purposes. For it will set forth the present state of invested capital for determining net earnings; the amount of annual depreciation of each class of equipment; the insurable values; and the amount of investment in each manufacturing department.

Then, too, as a basis for financial statements, such an appraisal ould carry far greater conviction than a mere generalized estimate of operating worth.

Moreover it is economically stable, based as it is upon invested capital; as, for example, is the computation of excess profits tax by ruling of the Treasury Department; and (rightly or wrongly) of public-utilities rates by the various rate-setting bodies. Upon it may be erected any temporary superstructure demanded by shifting dollar values and the like; but in itself it is like a bank account, which reflects money paid in for years, with corresponding withdrawals. Interest is paid on the balance in dollars, whether these will buy forty cents' worth or a hundred.

Morgan G. Farrell.[1]

New York, N. Y.

The Latin-American Situation Regarding Weights and Measures

To the Editor:

Carrying out the policy of the Society in encouraging discussion of papers presented at its meetings, I give below certain information recently secured relating to weights and measures in use in Latin-American countries and which corroborates that in a paper given two years ago before the Society.

Persistent statements, unaccompanied by facts, have been extensively circulated throughout the United States, tending to controvert the paper in question.

Several years ago the results of an investigation of the conditions regarding weights and measures existing in Latin America were brought to the attention of the A.S.M.E. Committee on Weights and Measures. This investigation had been made in order to obtain information as to what weights and measures were being used in South American countries, as to how far compulsory metric legislation had been effective in supplanting existing systems, and as to what degree confusion had resulted from an attempt to make the change to the metric system.

The sources from which they were received, as well as the representative character of those making reply, were believed to be of such a nature as to merit giving a résumé of those facts. The questions were submitted through the National City Bank of New York, the United Fruit Company, the *American Machinist*, and W. R. Grace and Company. The replies were tabulated and presented to the A.S.M.E. at the Annual Meeting, December 1918, and are to be found in Vol. 40 of Transactions, page 773.

[1] Director of Construction and Appraisal, Miller, Franklin, Basset & Co.

This investigation tended to show that after more than half a century of effort the old systems of weights and measures had not been eradicated, but instead had saddled an additional system on to what already existed, resulting not only in the expense of attempting to make the change but in augmented confusion following the attempt.

Corroboration of this has recently been received from what seem authoritative sources which it will be of interest to publish. The paper above referred to, Mr. Halsey's, was taken up for discussion by a metric advocate, who urges still further legislation to force the metric system on South America, apparently recognizing the failure of the efforts so far made in that direction, and admitting the present chaos resulting from the extensive use of other systems mixed with the metric system in those countries. The gentleman is Senor Carlos Basadre, of Lima, and his findings are published in the June 1920 issue of the *Bulletin of the Society of Engineers of Peru.* Referring to the paper, Senor Basadre says:

> Mr. Halsey's argument is manifestly powerful and based on demonstrated facts, and not merely on theoretical considerations. Without attempting to pass judgment on the advantages and disadvantages resulting from the adoption or rejection of the metric system as the single standard of weights and measures in the United States, let us consider some of the facts established by Mr. Halsey, the failure of the metric system in South America, and the idea that the old Spanish system can be brought into uniformity with the English system.....
>
> Latin-American countries adopted some time age the decimal- metric system; but, with the exception of Uruguay, contented themselves with recognizing it officially without troubling themselves at all to familiarize the mass of the population with its use little by little by means of an active and constant propaganda.....
>
> It can be stated that the official intervention alone has been effective, and this in an intermittent manner at such time as the confusion caused by the use or abuse of heterogeneous weights and measures has created a pernicious situation actually alarming.
>
> What has really happened is that the metric system has become mixed, sometimes more, at other times less, with the old Spanish system, with some English measures, and with the native measures, forming a heterogeneous conglomerate, which can be classified as a third system, peculiar to each country. If this chaotic state has been able to persist up to the present time, it is precisely because in the last analysis it has been the metric system that has always intervened to resolve all the uncertainties and confusions (translated from the original.)

The metric system was made legal in Peru in 1862. In 1869 an executive decree made that system compulsory for public business, and in 1920, fifty-eight years after the law was enacted, the results are as stated by Senor Basadre.

Mr. W. Graham Clark, Special Agent of the U. S. Dept. of Commerce, after several years' investigation of countries in Latin America, names in his reports the systems of measurement in nine of those countries, which he personally visited, and in every case he confirms the findings in the A.S.M.E. paper.

Mr. A. Hyatt Verritt, in a book entitled Getting Together with Latin America, states that he lived many years in those countries and names the systems of weights and measures of eighteen of them; he, with but one exception, confirms the statements of the report.

Mr. V. L. Havens, editor of the *Ingeneria Internacional,* who has had personal experience in most of the Latin-American countries, especially in the purchase of lumber, reports that the metric system is not used to any appreciable extent in the lumber industry, the English and Spanish systems being practically universal.

In *Commerce Reports* for April 21, 1919, in a summary of the various Consular Reports in which particulars are given of the weights and measures used in seven Latin-American countries, there is again a corroboration of the statements in the A.S.M.E. paper. The complete Consular Reports on this matter are now being studied and will be the subject of a later report, but it can now be stated that they fully bear out the statements which have been made as to the difficulty of making the change and the confusion resulting.

Shortly after the beginning of the World War, Mr. O. P. Hood made an investigation of the situation in South America as regards the machine industry. Mr. Hood, who is familiar with both the Spanish and Portuguese languages, spent eighteen months in the South American countries, and as a result of his investigation reported that 39.3 per cent of the machine tools there in use are of American make, while 43.2 per cent are British, leaving a remainder of only 17.5 per cent from possible metric countries. This

shows a preponderance of nearly 5 to 1 in favor of tools made on the inch basis in spite of the fact that Germany had during the prewar period an extremely energetic organization for selling and financing in those countries, and it is believed that German influence was largely instrumental in inducing them to enact legislation favorable to the metric system, such as would work into the hands of German interests.

As Chairman of the A.S.M.E. Committee on Weights and Measures, I would welcome any further information giving the actual facts regarding conditions affecting weights and measures in Latin America.

Luther D. Burlingame.

Providence, R. I.

Details of Diesel-Engine Clutches Used in German Submarines

To the Editor:

At the Philadelphia Navy Yard there is a large ex-German Submarine, the U-140, I believe. Last fall when the navy yard was thrown open to visitors for the benefit of the Naval Relief Association, I went aboard this vessel and was much interested in her

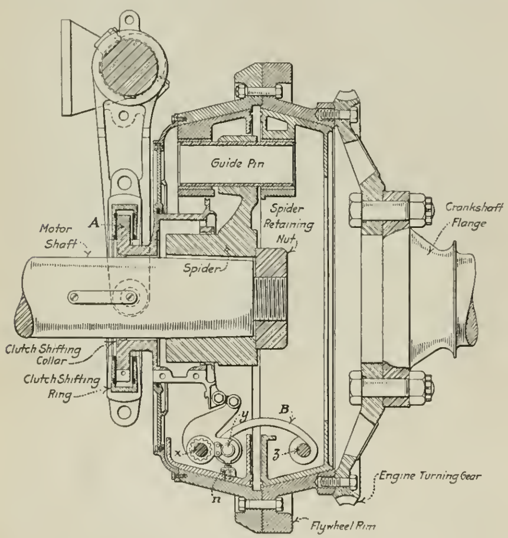

Fig. 1 Sectional View of Clutch

machinery; but what most attracted my attention was the clutches, which were very small for such powerful engines—Diesels, eight-cylinder, 21 in. bore by approximately 28 in. stroke as nearly as I could estimate.

These clutches may possess some very desirable features which would prove of value to our industries. Has the Society any information regarding these clutches or can it be obtained? Any information upon their design will be highly appreciated.

Marmaduke M. Wills.

Fitchburg, Mass.

[The foregoing letter was referred to Lieut-Comdr. Mark C. Bowman, U.S.N., Washington, D. C., who has very courteously supplied the desired information, based on drawings made by the Navy Department. Shortly before the close of the war Lieutenant-Commander Bowman gave a talk on the development of submarine Diesel engines before the Washington Section of the A.S.M.E. in which he showed intimate knowledge of the many details of design and construction. His communication relative to the clutch is given below.—Editor.]

Main Engine Clutches for German Submarines

To the Editor:

A general inspection of surrendered German submarines has indicated that engines for these vessels were of four standard sizes. A 10-cylinder 3000-hp. engine was built for installation in large cruiser submarines. A number of these engines were found in the shops ready for installation at the time of the signing of the armistice, but only one pair was installed in a boat, the U-142, which performed no active war service. Six-cylinder 1750-hp. engines, similar in cylinder dimensions to the 3000-hp. engine, were installed in the U-135, 136, 139, 140 and 141. A large number of 1200-hp. six-cylinder engines were installed in operating submarines and gave excellent service throughout the war. A fourth size, of 530 hp., six-cylinders, was found in late types of mine-laying and coastal boats.

The clutching device for connecting the engine and motor shafts is of special interest in view of the history of such devices in general and has led to numerous inquiries as to its construction. The same type of clutch was installed with each size of engine.

The clutch is of the double-cone friction type, of semi-steel and

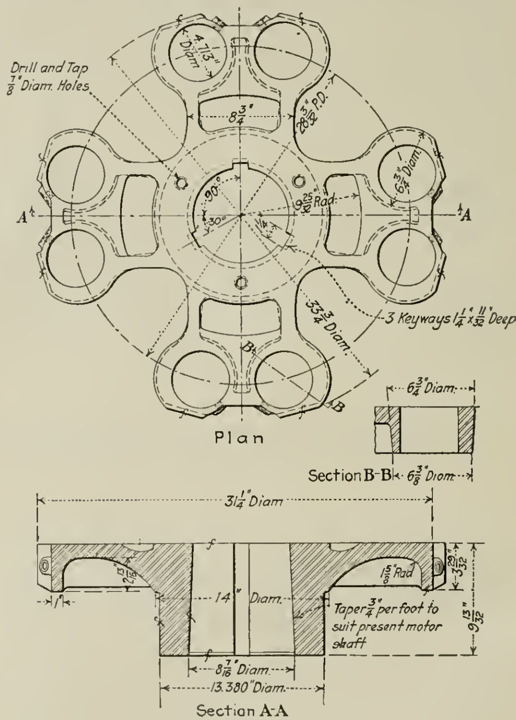

Fig. 2 Clutch Spider

cast iron, operated by air except in the 530-hp. size, which is operated by hand through worm and gear.

The outer casing or female member, which serves as the flywheel, is carried on the engine shaft. This casing, as shown in Fig. 1, is made in two parts bolted together with the inner surfaces machined to cone surfaces, the cones base to base.

The male part is attached to the motor shaft by three keys and a retaining nut, carrying a flange or spider in which are fixed eight large guide pins parallel to the shaft axis and extending through the spider on either side as shown in Fig. 1. Two inner clutch cones are carried on these guide pins, on which they here a sliding fit. They are of semi-steel and their outer or peripheral surfaces are finished to conform to the inner conical surfaces of the female or flywheel part.

In Fig. 2 are detail sketches of the spider and in Fig. 3 are details of the two male cones carried by the spider. These cones are alike except that stops are cast on the after cone (the cone nearer the motor) to limit the travel of the operating collar, as shown at X in Fig. 3.

The machined surfaces of the inner cones, Fig. 3, have oil grooves which insure that when unclutched or disengaged a complete film of oil will fill the clearances between the cone surfaces. The gradual squeezing out of the oil film as the surfaces are forced together enables the clutch to be thrown in when the engine is running.

The clutch is thrown in by forcing the inner cones apart until the male and female cone surfaces engage; and by drawing the cones together and thus releasing the surfaces the clutch is thrown out. The inner cones are drawn together or forced apart by a series of links and toggles actuated by a sleeve (A in Fig. 1) sliding on the motor shaft.

Referring to the lower half of Fig. 1, the center x is shown fixed to the forward cone and center z to the after cone. The clutch is engaged by separating centers x and z by forcing center y down to a line joining centers x and z. An adjusting cam around center x provides adjustment for wear in cones and bushings of the operating gear.

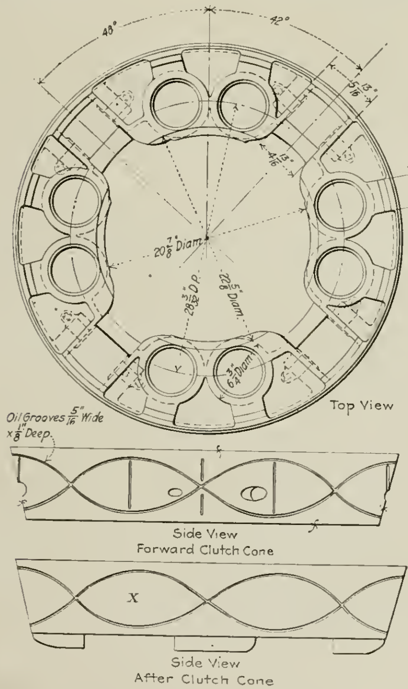

Fig. 3 Details of Clutch Cones

It will be noted that the forward link member B joining centers y and z (Fig. 1) is a steel leaf spring and that a further downward movement of center y against the stop n tends to decompress the spring slightly and to lock the mechanism. This spring is an important element in the mechanism. It is of chrome-vanadium steel with a tensile strength (annealed) of 80,000 lb. per sq. in. and an elastic limit of 50,000 lb. per sq. in. (annealed). It is heat-treated and quenched in oil.

There are four of these sets of operating links equally spaced and placed between pairs of pins in the blank spaces of the spider, Fig. 2.

Fig. 4 shows the clutch in diagram for the 1200- and 1750-hp. sizes, noting the principal dimensions, as also does the following table. No data for the 530-hp. and 3000-hp. clutches are now available.

Horse-power of engine	R.p.m.	Largest diam. revolving part, in.	Cone angle, deg.	Cone diameter, in. max.	min.	Area of friction surface, sq. in.	Crank-shaft diam., in.
1200	450	49-3/16	14	39-5/8	35-15/16	1765.112	9.453
1750	380	49-3/8	14	43-1/16	37-15/16	2608.297	11.219

The operating gear of the clutch used with the 1200-hp. engine consists of a double-acting air cylinder mounted on the floor just inboard of the clutch and connected to the ship's air line under 100 lb. pressure. The piston of the air cylinder drives a crosshead to which is attached a lever, the other end of which is keyed to a shaft supported by a fixed bracket above the clutch. The shaft leads over the clutch and drives a lever leading downward and end-

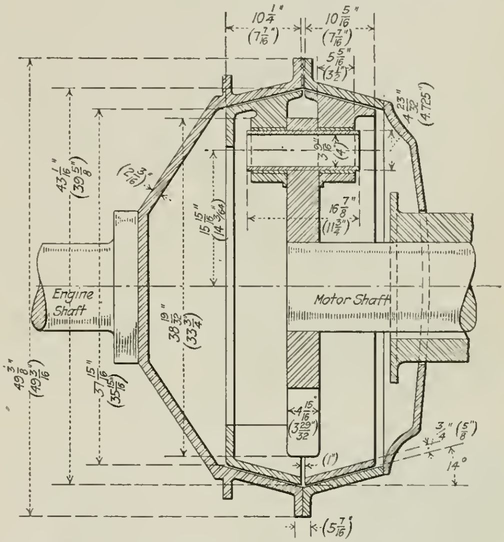

Fig. 4 Principal Dimensions of Clutches
(Dimensions in parentheses are for clutch for 1200 b.hp. at 450 r.p.m.; others for clutch for 1750 b.hp. at 380 r.p.m.)

ing in a fork end or yoke attached to a ring around the sliding collar which operates the clutch.

Assuming that the pressure of the air cylinder builds up to 100 lb. per sq. in. before the operation of clutching is complete and that maximum normal thrust in the cones is obtained when center y is 1 deg. above the line of centers x and z (Fig. 1), the following data are found:

Area of operating cylinder = 18.665 sq. in.
Force on crosshead = 100 × 18.665 = 1866.5 lb.
Force on operating collar through levers = 3732 lb.
Resolved force at center y normal to line of centers, = 1925.2 lb., which produces an axial thrust on each cone of 1925.2 tan 1° = 110,012 lb.
Normal thrust = 110,012 × sin 14° = 26,621.9 lb.
Total normal thrust per cone = 4 × 26,621.9 = 106,448 lb.
Friction area of each cone = 882 sq. in.
Unit pressure = 106,448/882 = 120.7 lb.

Referring to the engine itself,

B.hp. of engine = 1200; r.p.m. of engine = 450
K = coefficient of fluctuation of turning moment = 1.6 for 6-cyl. engine.
M = maximum turning moment of engine in in-lb. = $\frac{1200 \times 63{,}000 \times 1.6}{450}$ = 168,000 in-lb. × 1.6 = 268,800 in-lb. Assuming now that
N = total normal pressure on cones; R = mean cone radius
f = coefficient of friction; $N = M/fr$; $f = M/Nr$

then $f = \frac{268{,}800}{106{,}488 \times 18.89} = 0.133$ (coefficient of friction for steel on iron, freely lubricated).

The Opportunity of the Engineer

Dexter S. Kimball

The ease and promptness with which the public as a whole becomes accustomed to and takes advantage of the work of the engineer, using the term in a broad sense, is almost startling. Surprise at and fear of radical innovations in transportation and private service quickly give way to blasé indifference followed instantly by all manner of criticism that these things are not better constructed and managed.

Little outbursts of criticism should not be construed (as they are by some people) as indicating a lack of appreciation of the work of the engineer. They are an integral part of the influences that make for progress. The world in a way has always obtained as much engineering talent as it demanded. It is true that the engineer and inventor have had a tremendous influence in changing man's environment and in making this old earth comfortable and more habitable; but it is also true that these same engineers are, to a large extent, products of their own surroundings; and much of their progress has been made by supplying wants created by the public.

If the engineer has not been appreciated as much as some other classes of men, it is because his service to humanity has not been the highest. The men who render the greatest service to any nation are those who mold its *ideals*, and the philosopher and the poet will continue to wear the bays as long as they lead in this line. True, the work of the engineer has made it possible for us to realize more fully our ideals if we could only take full advantage of the productive processes which he has developed and the leisure that should result therefrom; for every day makes it clearer that highest mental and moral development rest primarily on material prosperity. It is difficult to be high-minded and hungry at the same time.

The engineer most naturally applied his scientific method first to constructive engineering and it has become second nature with him to collect data, to analyze the same and to plan work and predict results on this solid basis. But the administration of modern industry has come to require a considerable knowledge of constructive art, and the natural tendency to seek a solution of the problems of administration on the basis of accumulated knowledge rather than on an empirical basis has made an opportunity for the engineer that has carried him far afield and brought him closely in touch with the administrative side of both private and national affairs. To this new field he has quite naturally brought the analytical methods of his calling, and the art of management bids fair to be placed on a much more rational footing because of his labors in this new field of activity. *Compilation, analysis, prediction,* are the methods he is employing, and stripped of all its technical terms and high-sounding titles so-called Efficiency Engineering or Scientific Management and its correlated branches represent an effort to raise business management of all kinds from the vague empirical basis on which it now rests and place it on a scientific footing comparable with constructive processes. The progress which this movement makes will, as before noted, depend not on the effectiveness of these methods alone, but on the reactive influences which it meets with or awakens. Efficiency is not the sole criterion by which industrial phenomena are to be finally judged. Whether we will it or not, industry is being looked upon more and more as a means of supporting human existence and less as a means of creating individual or corporate dividends. The most efficient kind of factory for the creating of dividends would be equipped with the highest order of labor-saving machinery and management and operated by slaves. And as we move farther and farther away from this extreme ideal so we will become more and more critical of processes and methods of production. It is going to be a nice problem in social and political organization to reconcile the many conflicting reactions, and the full import of the movement will be more and more appreciated as our natural resources become more depleted and the struggle for existence becomes keener.

The influence of this new study on the engineer himself will be far-reaching; for he must draw his basic facts for this work not only from his own field of engineering but also from economics, accounting, psychology and other sciences which heretofore he has known little or nothing about, or has ignored. And this has brought him very close to the pivotal problem of our civilization, namely, the fair and equitable distribution of the wealth which he is so instrumental in creating. If he can master the fundamental truths that lie at the bottom of the problem or if he will have the wisdom and foresight to call to his aid the masters of thought in these lines, it is not beyond reason to hope that as he has conquered the problems of production and is now conquering the problem of administration he may evolve from his riper experiences in these fields a solution of the remaining problem which will be satisfactory to all. It is apparent that the solutions already offered fail to satisfy; but it by no means follows that these are the only possible solutions any more than the old methods of management were the only ones possible. In fact, as we look back even a few years the philosophies of engineering and manufacturing as then practiced seem very inadequate indeed; and the theories of management of yesterday are rapidly passing into obsolescence. We are sadly in need of a new type of industrial philosophy and new methods of distribution. We are in need of a new type of industrial leader; and I believe that if he comes at all in the near future he will come from the ranks of the industrial engineer, using the term in the broadest sense. It is true that other classes of men are familiar with and use the engineer's methods, but he is going to have a particularly advantageous position from which to attack this problem, for the near future will see him a dominant figure in industrial management where he will meet the problem at first hand. Here is his opportunity. It is hardly likely that any one man will be able to solve this difficult problem, and if it is solved it will probably be the work of many brains. But the man who first points out the way to a solution will not need to envy any man his glory, for posterity will surely place him in the ranks of the immortals.

I have every confidence that the engineer will rise to this opportunity and there are many signs that these ideas are stirring in the minds of forward-looking engineers. It is with no small gratification that we all see the elevation of our past-president James Hartness to the gubernatorial chair of his own state, and see Mr. Hoover, an engineer by training and experience, a member

of the cabinet of the new administration. These are pioneer workers in a field where the lawyer and the politician have long reigned supreme, and their stewardship will be watched by all engineers and others with great interest. It is an auspicious beginning that should hearten all who believe in the application of scientific methods to all problems of human existence.

Dexter S. Kimball.

A Place for Non-Scientific Management

Ralph E. Flanders

THE problem of organizing a large machine shop is naturally solved in different ways for different conditions.

For the manufacture of a single product on a large scale—an automobile chassis, for instance—the shop is usually departmentalized according to its product, particularly where the output is great enough to permit continuous production in most of the operations. Thus there will be a department for camshafts and crankshafts, another for rear-axle bevel gears, another for transmission gears, etc.

At the other extreme, where there is a wide variety of product in varying quantities, the usual scheme has been to departmentalize the factory along the line of processes. Thus there will be a milling department, a drilling department, a grinding department, etc., common to all the various products. These are often combined with separate heavy machining and assembling departments, each devoted to a special product.

There is a third method, not often followed, which has decided advantages for the shop manufacturing a limited line in quantities which do not vary too widely. This consists in dividing up the plant into separate departments, one for each of the products and each practically complete in all of its details for the manufacture and storage of parts and for their assembly into completed machines.

At first sight such a solution seems like a backward step, but its advantages become more apparent on study and particularly after actual trial. Our modern methods of management have become absurdly complicated and topheavy, but the proposed method remedies the evil by simplifying the problem. Among other advantages it affords the following:

The entire parts manufacture for a product can be concentrated in one department, eliminating interdepartmental correspondence and friction.

A recurrent routing program can be established, free from the interruptions of other products, so that routing is standardized instead of being in a chronically unsettled state.

Machines may be placed in the general order of the operations and the whole department located beside the stock room, which in turn adjoins the assembling department. Thus trucking and the supervision of widely scattered parts are greatly simplified.

To sum up the possibilities, it may be said that the whole scheme of management may be so arranged that *reference is made to the work itself*, moving in its appropriate channels, instead of to cards or other records. These are often inaccurate and always expensive, and are usually located in some quiet spot far from the scene of action.

It is unnecessary here to go into the various arrangements required to maintain proper relations with other divisions of the work, or for taking care of the unescapable breakdowns of machines and systems. These problems are, in fact, less serious than with more complex schemes of organization.

My faith in the plan is based on my belief that a few ordinary mortals with energy and fair ability can handle separate divisions with success where the work is so arranged that it can be touched by the hand, seen by the eye, and comprehended by the brain; and that the same men will work much less effectively when handling interdependent departments, run by a system of reports and records, even though presided over by a harassed superman of a scientific manager.

Ralph E. Flanders.

The Engineer Cabinet Member

IN placing Herbert Hoover in nomination for the presidency of The Federated American Engineering Societies at Washington, Dean Kimball said that at Leland Stanford University, when Hoover was a student there, it was recognized by those who knew him that "here was a man who would go very far and achieve much in whatever field of activity he might be placed." Mr. Hoover's entry into the Cabinet is but another step in the fulfilment of that prophecy—a step which will be especially gratifying to all engineers in every country of the world.

For Herbert Hoover belongs not exclusively to America, but, in a peculiar sense, to the whole civilized world. He has not been chosen for this new honor simply because he is an engineer, but because of his demonstrated capacity for rendering service of an exceptional character. In short, because he is Herbert Hoover, unselfish, devoted organizer and director of the world's greatest benefaction, preeminent preserver of human life and of faith in human nature.

His fellow-engineers will rejoice in the fact that added to his personal and natural ability have been the training and experience of the engineer with the habit of a clearly defined objective, of marshaling all possible forces of personnel and matériel for the attainment of that objective and directing them in such manner as to secure the hearty, whole-souled devotion and coöperation of myriads of men and women.

His recognition is not based upon partizan political service, past or prospective, but upon the world's conviction that this engineer possesses in preeminent degree the ability to perceive what needs to be done and to organize and direct the means of doing it. Especially have the newly enfranchised women of the country insisted that his genius should be enlisted in the service of the people, and in this they have shown an ability and disposition to recognize genuine service to humanity and to the social order which must be reckoned with by those who in all future times may endeavor to guide political affairs.

By tradition our public offices have been filled mostly by men whose training has been in the law. There have been many good reasons for this, but the time has come when the constructive and directing ability of the engineer is required for the solution of our present-day problems, which are largely brought about by changes in our manner of life resulting from the work of engineers. It seems certain that in greater and greater numbers engineers will be called to serve the people in public office.

Mr. Hoover has set his own high standard of public service and his responsibility to the public will be correspondingly great. We may be sure that his only conception of rendering real service to the administration of which he is a member will be to render a real and genuine service to the people of the country, without regard to partizan considerations.

Whether or not Mr. Hoover is to be followed by a long line of engineers in high and responsible official positions, depends now far more upon him and how he shall conduct himself during his term of office than upon anybody or anything else. His responsibility on that score is to the engineers not only of the United States but of the entire world, all of whom are familiar with his achievements and know that they will be themselves appraised more or less by the degree to which he is successful. Fortunately, no engineer will for a moment doubt that this responsibility also will be most faithfully and competently discharged.

Fred J. Miller.

The Unstabilized Dollar and Efficient Management

THE most striking feature of Professor Irving Fisher's address, How an Unstabilized Dollar Interferes with Efficient Management, at the Springfield, Mass., meeting of the Taylor Society, was the response of the audience of practical plant executives and industrial engineers. It was evident that those who are charged with managerial responsibility in industry have come to appreciate that here is a problem which should no longer be classed as merely "academic." The responsiveness of the audience was no doubt in part due to Professor Fisher's great ability as a speaker

—he is unexcelled in clear and interesting presentation—but it was also due to the timeliness of the discussion. One who has just come from the painful task of writing off inventories following the violent price fluctuations accompanying the change from a sellers' to a buyers' market, is ready to consider as practical and urgent the question whether defects in the monetary system may not be in part responsible—and may not be remediable.

Professor Fisher's discussion followed the well-known and unexcelled four-part outline usually employed by the late Professor Sumner. In answer to the question, What is it? the attention of the audience was called to recent general price fluctuations as evidenced by that new instrument of precise measurement, the index number. In answer to the question, What causes it? the author called attention to the fact that in the United States the value of a dollar is the value of 23.22 grains of gold, and that as the quantity of gold and media of exchange based on gold, including credit tokens, increases in volume, more gold and therefore more dollars will be offered for other commodities (higher prices), and that as the quantity of gold and media of exchange based on gold decreases, less gold and therefore fewer dollars will be offered for commodities (lower prices). In answer to the question, What of it? Professor Fisher reminded the audience of the unwholesome, feverish business activity which results from violent increases in general prices, the stagnation resulting from the uncertainty accompanying violent decreases in prices, the losses to recipients of fixed income—bondholders and salaried persons—in times of price increases, the losses to owners of businesses—stockholders and farmers—in time of price declines, and in general the unfavorable influence on establishing and carrying forward managerial plans in the face of price changes one way or the other. Taking up last the question, What are you going to do about it? the speaker explained his own proposition for stabilizing the dollar and argued that as a practical problem of establishing a better environment for promoting stable conditions for good management the business community should encourage the legal adoption of it or of an equivalent method of solving the problem.

Professor Fisher's plan is to change the law, so that instead of a dollar always having the value of 23.22 grains of gold, the amount of gold which shall have the value of a dollar shall be periodically automatically changed as *general* prices change, as measured by the index number; as prices tend to go up, more gold, as prices tend to decline, less gold, shall have the value of a dollar. The result would be to maintain the quantity of dollars to be offered for commodities stationary, even though the quantity of gold might change. In that way, Professor Fisher believes, *general* prices can be kept fairly stationary. And stable general prices will create a better environment for administrative and managerial plans and activities—a better opportunity for developing generally more precise and therefore better management.

It is essential that business executives and engineers give more thought to such problems. Their traditional attitude is to consider outside their range of interests a study of the social forces which determine the limits of their managerial activities. Unfavorable social conditions they consider "acts of God" which may not be influenced and to which they must submit. They are as a matter of fact generally the acts of men.

The reaction to Professor Fisher's address gave evidence that engineers and executives are showing a greater interest in general economic problems and a disposition to bring their influence to bear on stabilizing the conditions under which they must conduct their business activities. H. S. Person.

San Francisco–New York Mail Delivery and the Railroads

The recent success in delivering mail from San Francisco to New York by aeroplane in less than 34 hours is of considerable interest, not only in aeronautics but in relation also to railroading.

Beginning 20 years ago, and up to the time of the war, vigorous efforts were made to increase the speed of passenger and mail transportation by rail. In Europe the effort was directed to determining the maximum possible speed of transportation with electric locomotives, and in tests at Zossen, Germany, a speed of 200 kilometers (124 miles) per hour was attained. The requirements of operation, however, were so severe as to show the utter impracticability of such speeds for regular traffic, especially when of transcontinental character.

In America the steam locomotive was relied upon to give the fastest possible transportation, but as early as 1910 there began to be the feeling that we had very nearly reached the limit of speed compatible with safety, and that the disturbance to regular traffic occasioned by these fast trains more than offset any advantages which might accrue. This feeling found expression in the addition of two hours of traveling time to the crack New York Central trains between New York and Chicago.

It costs money to lop off even one hour's time between New York and Chicago; and it would cost proportionately more to reduce the time, say 10 hours, between New York and San Francisco, involving as it would a large permanent investment for improvements in roadbed and roadbed equipment, additional trackage at stations, etc.

As long as rail transportation was the only means available for transcontinental traffic there might have been good reasons for going to such expense, but the wisdom of such a course becomes more and more doubtful with the development of aerial service.

While as yet the aeroplane and dirigible are far from being competitors of the railroads, there is every reason to think that one or both will become so for long-distance high-speed mail and passenger traffic, just as the motor truck has become a competitor in short-haul freight transportation—and this within a very few years. This is all the more to be expected from the fact that the demand for high-speed traffic over long distances is at present comparatively small in volume.

The fast letter mail has already been practically taken off the ground. An interesting example of what is being accomplished by the mail service as now established is the reported receipt of a letter at the Engineers' Club, New York, 50 hours after it was mailed at Los Angeles. This letter traveled by aeroplane by day and by train at night, apparently via Omaha and Chicago.

In case the appropriation should be forthcoming, the Post Office Department is stated to have plans for a regular 36-hr. service from San Francisco to New York on the strength of the showing already made.

It will very likely take a good deal longer to lift off the ground the high-speed passenger traffic, but there is scarcely any doubt that this is coming, and, this being so, it does not seem likely that the railroads will ever incur the heavy investment and expense of operation that would be required to cut even half a day from the time between New York and San Francisco, when the chances are that air transportation would cut off two days.

There also looms in the distance the possibility that by utilizing the high-velocity winds apparently ever present at great altitudes, the transcontinental timetable may become a matter of hours rather than of days. It was whispered last fall that the War Department would try during the coming summer a dirigible trip from San Francisco to the Atlantic Coast to follow a trail, say, 30,000 to 35,000 ft. high, with the expectation of making the trip within the scarcely believable time of 10 hours from start to finish.

Progress Report on Superpower Survey

A report submitted late in February to President Wilson by John Barton Payne, Secretary of the Interior, outlines the work which has already been accomplished and indicates what is yet to be done by the Geological Survey in its study of methods for the further utilization of water power and the special investigation of the possible economy of fuel, labor, and materials resulting from the use in the Boston-Washington industrial region of a comprehensive system for the generation and distribution of electricity to transportation lines and industries.

An engineering staff, with William S. Murray as chairman, assisted by an advisory board of business and professional men, of which Prof. L. P. Breckenridge is chairman, is making a thorough study of the problem in its physical, legal and financial aspects. An editorial outlining the plan of study, describing the field, and naming some of those engaged in the work, was given in the November 1920 issue of Mechanical Engineering, p. 642. It is believed that the complete report will be available in July.

The Material-Handling Problems of Ports

Interesting Meeting Held at Newark Under the Auspices of the Materials Handling and Metropolitan Sections of the A.S.M.E.

THE Materials Handling Section presented a program under the auspices of the Metropolitan Section at a meeting held in Newark, N. J., on the evening of March 4, 1921. Following dinner at the Robert Treat Hotel, about 700 members gathered at the Public Service Terminal Building to hear a series of papers devoted to a discussion of the material-handling problems of port operation. The first paper was presented by B. F. Cresson, Jr., chief engineer, N. Y., N. J. Port and Harbor Development Commission.

Mr. Cresson presented the fundamental considerations in the development of a port, upon which the remainder of the program, relating particularly to the use of material-handling apparatus and methods, was built.

Mr. Cresson pointed out that a world-trade port should be able to handle great volumes of business and great varieties of commodities. A great port should comprise a protected deep-water harbor, a substantial length of waterfront, a hinterland of industrial importance, a system of railroad and inland waterway connections to a large producing territory, a good labor market and an appreciation by the political government of the necessities in the layout, ownership and administration of the port facilities. A form of port administration should direct the growth and operation of the port, making it as cheap and easy as possible for commerce to enter and to leave, not seeking to obtain high revenue from the operation of port facilities, but developing them and using them rather as a means to build up the territory tributary to the port. There must be facilities for the handling of bulk commodities and there must be the necessary equipment for the handling of the miscellaneous package freight.

The problem that the port engineer is usually confronted with is the layout within an operating port district of terminal facilities that will best coördinate the transportation lines, both land and water, centering at the port, and in so doing to create a district in which business may expand. Mr. Cresson spoke of the zoning of ports, first, by the segregation of large commodity business, and second, by the segregation into separate districts of business in principal trade routes.

In the development of a port there must be considered, first, the proper location of the terminals; second, the physical layout of the terminal facilities; third, the equipment of the terminal facilities; and fourth, the administration and operation of the port as a whole. The layout of a terminal should depend upon the character of business to be handled, the ships and other craft that are to dock there, and the location of the railroads and highways. These factors affect the width and height of the piers, the placing of tracks, the building of sheds, the width of slips, etc. In some instances the quay system is superior to the pier system. In any case a port must be made up of many different parts, and these should be coördinated not only in their location, design, layout and equipment, but also in their general administration and operation.

The speaker pointed out the importance of the Port Newark Terminal and emphasized the possibility of the construction of a modern terminal that will develop industries and permit rapid and cheap interchange of freight between rail and water carriers.

Treating the subject of Machinery for Cargo Handling, J. A. Shepard, vice-president of the Shepard Electric Crane & Hoist Co., outlined the development of devices for moving cargo in and out of the holds of ships, indicating the limitations which the necessity of stowing away cargo by hand power imposed and discussing some types of pier machinery. Mr. Shepard made a plea for the development of smaller but more efficient terminal units, thoroughly equipped with mechanical apparatus giving efficient results and large output per unit.

E. Logan Hill, of Heyl & Patterson, Inc., in discussing Car Loading and Unloading Machinery, confined his remarks to apparatus suitable for handling miscellaneous package freight from box and open-type cars to platforms, piers, lighters, and steamships.

Mr. Hill traced the progress in the manner of unloading such material from cars, through the steps of hand labor and hand-operated derricks, steam locomotive cranes, to specially designed electrically operated cranes. Three distinct types of electric cranes were mentioned as satisfactory for this work. These are, in the order of their efficiency and first cost:

1 A steel gantry structure, spanning one or more tracks and having mounted thereon apparatus which to all effects and purposes is the same as the locomotive crane without the boiler and steam engine, the motive power for hoisting the load, rotating the crane and luffing the boom being supplied by one motor with a multitude of clutches, brakes, brake bands, gear levers, etc.

2 The so-called straight-line crane, which consists of a tower structure and a boom which in operating position is held in a horizontal plane and has no provision for working at any other angle and is incapable of being rotated about a central point.

3 The full-arch or semi-portal traveling revolving jib crane.

The speaker then went on to discuss a typical installation of an open-type railroad pier approximately 1000 ft. long and 80 ft. wide, on which were placed a number of parallel tracks. Eight steam locomotive cranes were replaced by four traveling full-arch revolving jib electric cranes having separate motors for each of the several movements such as hoisting, rotating and traveling. The maintenance charge of the eight locomotive cranes for twelve months was practically $34,000. The four electric cranes which replaced the locomotive cranes had a maintenance charge of $7500 after they had been in service for nearly four years. The four electric cranes actually handle more material than was ever handled by the eight locomotive cranes. They require 14 less men, which, taken into consideration with the increased amount of material handled, resulted in a total saving per annum of approximately $45,000.

The portal structures of these cranes are designed so as to span two railroad tracks, their movement up and down the pier is entirely independent of any switching movement, and their booms are of such length that they can reach any car on any one of the five tracks of the pier.

In concluding the discussion, R. S. Parsons, general manager of the Erie Railroad, called attention to the great importance of coöperative action on the part of the people of New Jersey in the development of a port of New Jersey. He contrasted the action in New York, where three counties are combined under one specific head, with the situation in New Jersey, where some 15 separate municipalities are struggling with jealousies and petty problems and the great problems are ignored.

Between the presentations of the papers reels of moving pictures of New York Harbor and of Newark Bay were shown.

Four Test Codes for A.S.M.E. Spring Meeting

A.S.M.E. Codes must be presented for adoption by the Society at a regular meeting. A feature of the Chicago Meeting will be a session devoted to the consideration of the proposed Power Test Codes on General Instructions, Reciprocating Steam Engines, and Evaporating Apparatus. This session will be in the nature of a public hearing, and every one who is interested in these Codes or in any one of them is invited to be present and take part in the discussion. The Code on General Instructions appeared in the December issue of Mechanical Engineering; the Code on Reciprocating Steam Engines in the January issue, and the Code on Evaporating Apparatus in the March issue. Written discussion on all of these Codes is also invited from those who are unable to attend the Power Test Code session, and should be addressed to C. B. Le Page, Secretary to the Committee, 29 West 39th Street, New York.

The Elimination of Waste in Industry

Purpose and Plan of Work of Committee Appointed by Herbert Hoover, President of The Federated American Engineering Societies

THE membership of The Federated American Engineering Societies consists of national, local, state and regional engineering and allied technical organizations and affiliations. Such national engineering societies as The American Society of Mechanical Engineers, American Institute of Electrical Engineers, and the American Institute of Mining and Metallurgical Engineers, are members of The Federated American Engineering Societies.

The object of the organization, as quoted from the Constitution,

> ...Shall be to further the public welfare wherever technical knowledge and engineering experience are involved, and to consider and act upon matters of common concern to the engineering and allied technical professions. ......A comprehensive organization of the community, state and nation.

The Committee on Elimination of Waste in Industry came into existence from a speech in Washington by Mr. Hoover, in November, in which he said:

> It is primary to mention the three-phase waste in production: first, from intermittent employment; second, from unemployment that arises in shifting of industrial currents; and third, from strikes and lockouts. Beyond this elimination of waste there is another field of progress in the adoption of measures for positive improvement in production.
>
> In the elimination of the great waste and misery of intermittent employment and unemployment, we need at once coördination in economical groups ..

In an executive meeting of the American Engineering Council, Mr. Hoover further discussed the need for an intensive study being made of all causes for industrial waste, emphasizing those factors that contribute to labor or man-power waste. He suggested to the Council, which is the governing body of The Federated American Engineering Societies, the advisability of appointing a committee of fifteen carefully selected engineers to undertake a study of waste in industry. The American Engineering Council readily approved the suggestion of Mr. Hoover, whereupon he then formed the Committee on the Elimination of Waste in Industry.

In selecting the personnel of this Committee, care was exercised to secure men of broad experience, of clear concepts, of unbiased attitude toward labor problems and representative of managerial, consultant, educational and editorial activities, as well as having a widely distributed and a varied industrial contact.

At the organization meeting of the Committee in January, its purpose was stated to be—

1 To determine the cause of labor, material and equipment waste in industry. The material and equipment phases of the problem to be studied only in so far as they may cause labor waste.

2 In so far as possible to determine the extent of the waste that arises through each major cause.

3 To suggest means of removing the cause for such waste.

To accomplish the purposes of the Committee, it has been found necessary to make studies along the following lines:

1 Organization—that which assigns responsibilities and relationships, and the discharge thereof.

2 Engineering—which comprises the design, construction and maintenance of plant, machinery and tools and the design of the product.

3 Production Control and Cost Control. Under this division fall all the factors relating directly to production and the proper direction and accounting therefor.

4 Physical Factors. This division relates to the storage and inspection of raw and processed materials and to matters of internal transportation. It also includes consideration of the physical condition of the plant as regards lighting, heating, toilet facilities etc.

The first and third sections, as well as the principal part of the fourth, directly relate to the human element in industry. The Committee is devoting the major portion of its effort to the factors that affect the human element.

The important subdivisions of the major factors—organization, production control and cost control,—to which special attention is directed, are enumerated below.

ORGANIZATION

(a) *Nature of operation:*

1 Contractual. This form presents many problems that affect personal relations. Building operations largely contractual. This form of relationship is quite common in the clothing industry.

2 Repetitive. A large portion of industrial activity is repetitive. This phase of industry makes prominent the question of monotony, and occupational diseases.

3 Continnous. Steel and chemical industries are typical representatives. In this form of operation the question of the number of shifts is considered important.

(b) *Types:*

The type of organization is some index to the quality of the management and as such is an essential consideration.

1 Functional
2 Line and Staff
3 Staff
4 Mixed
5 Committee.

(c) *Personal Relations:*

1 Employment Policies

2 Representation—To what extent each plan has been tried, and with what results:

a Federal plan
b Joint committee
c Employees'coöperative association.

3 Strikes and Lockouts—The case for, the duration of, the man-hours lost, and the total cost.

4 Restrictions by Management and Labor—An investigation of the means employed by management and by labor to restrict production. Such practice produces an unstable condition and hence leads to uncertain labor conditions and disturbed relations.

5 Unemployment
a Quantity of
b Causes of
c Remedy for.

6 Seasonal and Intermittent Employment
a Qnantity of
b Causes of
c Remedy for.

PRODUCTION CONTROL AND COST CONTROL

(a) *Planning:*

All of these factors have a direct influence upon the productivity of the individual worker. If inadequately or ineffectively provided for, the worker loses time and compensation, hence a high morale is not snstained.

(b) *Establishing Standards:*

This is very significant, as many labor disputes have arisen over the method and fairness used in establishing such standards. They have a direct bearing upon the earnings of the worker.

(c) *Maintenance:*

If equipment is not properly maintained, the operator does not accomplish standard tasks, hence dissatisfaction results.

Industries to be Studied. The representative industries which have been selected because of their general importance and interest to the public are as follows:

1 Bituminous Coal	6 Paper
2 Building Trades	7 Metal Trades
3 Transportation	8 Textiles
4 Men's Ready-Made Clothing	9 Shoes
5 Printing	10 Rubber

From three to ten plants of each selected industry are being visited by an experienced engineer, who will secure the information desired by the Committee. A carefully prepared list of questions has been placed in the hands of each field worker. The information obtained by the field investigator is to be supplemented by such authoritative data as may now exist in the form of reports made by reliable parties or agencies. Through this means sufficient information is to be secured to enable the Committee to formulate specific conclusions as to the major causes of industrial waste.

Staff. A small staff is to be maintained at headquarters. This staff plans and directs the work. The field work is to be done by engineering firms carefully selected for their fitness for the work. For example, the investigation of ready-made clothing was assigned to a firm that has had a large experience in that field. Thus the

Committee will obtain the benefit of the experience and knowledge of the firm that has had most intimate contact with a given industry. The firms are doing the work at actual cost to them, all profit being waived.

All authoritative literature upon each general topic is to be carefully searched and digests made by well-qualified firms. The headquarters staff will compile all the data and write the final report, which is to be reviewed by the Committee as a whole. Every effort is to be made to secure authentic and quantitative information, and care will be exercised to prevent any bias or prejudice from influencing any phase of the work.

Progress of Work. The work of the Committee is well under way. Reports on the first investigation in each industry were made on February 21, carrying out the time schedule set February 7. At a meeting of the Planning Board held on March 1, further reports were presented and plans made for continuing the investigations more intensively. These reports were uniformly encouraging and there is every reason to believe that the investigation will yield information that will have an important bearing on the nation-wide movement inaugurated by the engineer to eliminate waste in American industry. In New York, New England and Pennsylvania the fuel investigation is practically completed.

Engineers Asked to Urge Reconsideration of Nolan Patent Office Bill

The following report of the Patent Committee of the American Engineering Council is of importance to all engineers and should receive their immediate attention. The Patents Committee, in submitting the report, asks that every member of each of the constituent societies of The Federated American Engineering Societies immediately write his representative and his senators and the chairmen of the Committees on Patents of the Senate and the House of Representatives, urging the reintroduction and passage of the Nolan Patent Office Bill without the section known as the Federal Trade Commission section.

The bill for the imperatively necessary relief of the Patent Office, after passing the House of Representatives with satisfactory provisions for the Patent Office, failed to pass the Senate at the session just closed with those same provisions, solely because of the presence in it of an unrelated section known as the Federal Trade Commission Section.

The former opposition in the Senate to the Patent Office relief and that which forced the unacceptable reductions in salaries and numbers of examiners and clerks (which the Conference Committee was persuaded to set aside) is largely and seemingly almost wholly overcome. But the opposition in the Senate to the Federal Trade Section is determined and has expressed an intention to prevent the Patent Office from getting the desired relief, unless the Federal Trade Section is removed from the bill.

More than preventing the Patent Office relief, however, the Federal Trade Section is believed to be a dangerous measure in itself, It provides that the Federal Trade Commission may receive assignments of and administer inventions and patents from governmental employees and is an entering wedge for further legislation to empower the Trade Commission to receive patents from non-governmental inventors or owners. An exclusive license would have to be granted, at least for a few years, to induce any one to undertake the almost always necessary development expense, and the Trade Commission would surely be charged with favoritism in granting such a license. In order to protect its licenses, the Trade Commission would have to sue infringers, a most unfortunate activity for the Government. The industries would close their doors to the government employees, fearing to disclose to them their secrets or unpatented inventions, and research by the industries would be discouraged for fear that government employees, using government facilities, might reach the result first and patent it. The Trade Commission, owning a large body of patents, in case that one of its patents was found to be infringed during or at the close of a frequently very expensive development by private interests would be able to dictate in the license the price at which the article, which was the object of the development, could be sold, or to dictate other similar conditions, thus depriving the development of much of its value; and could even require the licensee, as a condition for granting needed license, to practically destroy some of its unrelated patents, as by licensing the trade generally when it would prefer to retain the monopoly for itself.

The foregoing and other objections would result in making patents less desirable to own or to purchase, and consequently would decrease the incentive to produce inventions, which production is the main purpose of our patent system.

The proposed section is unnecessary for the protection of government employees, since they now have all the rights which non-governmental employees have to patent inventions and to sell them. It is therefore believed that the Federal Trade Commission section should not be enacted into law in any form, even as a separate bill.

Award of Kelvin Gold Metal

The first triennial award of the Kelvin Gold Medal has been made to Dr. William Cawthorne Unwin, F.R.S., of London, for his preeminence in the branches of engineering with which Lord Kelvin's scientific work and researches were closely identified. The Kelvin Gold Medal as instituted eight years ago when the leading engineering societies of the world coöperated in securing a memorial to Lord Kelvin, a distinguished engineer and man of science. The major memorial took the form of a window in Westminster Abbey. The Kelvin Medal was established from the remainder of the memorial fund. The Kelvin Gold Medal Fund is administered by the Institution of Civil Engineers. The committee making the award, in accordance with the conditions of the Kelvin Medal Trust, consisted of the presidents of the principal representative British engineering institutions.

Dr. Unwin has been professor of mechanical and hydraulic engineering at the Royal Indian Engineering College and professor of engineering at the Central Technical College of the Guilds of London. He is a past-president of the Institute of Civil Engineers and an honorary member of The American Society of Mechanical Engineers.

Dr. Unwin has done work of great importance in the development of precise methods of testing, in connection not only with materials but also with all types of power plant. The standardization of specifications now being carried on by the British Engineering Standards Association owes much of its success to his pioneer work. In the work of coördinating results of experience in engineering design, in the development of centrifugal pumps and the hydraulic generation of power, in increasing the efficiency of heat engines, and in machine design, the influence of Dr. Unwin, both as a writer and as a teacher, has been far-reaching.

Engineer Appointed to Public Service Commission of Maryland

Governor Ritchie of Maryland has recently announced the appointment of Ezra B. Whitman, civil engineer, and president of the Engineers' Club of Baltimore, as one of the three public-service commissioners of the state. In the announcement emphasis was laid particularly on the desirability of having a trained engineer on this board.

Mr. Whitman was graduated from Cornell University in 1901, and afterward took special courses in chemistry and bacteriology in the Cornell Medical School, New York. From 1902 to 1905 he was a member of the firm of Williams and Whitman, of New York City. From 1906 to 1911 he acted as division engineer for the Sewage Commission of Baltimore, in charge of the design and construction of the sewer systems for that city. From 1911 to 1914 he served as chief engineer and president of the Water Board of Baltimore City, in charge of the maintenance, operation and extension of the system. From May 1914 to May 1916 he was a member of the firm of Greiner and Whitman. Since 1916 he has been a member of the firm of Norton, Bird and Whitman, who have carried on a very extensive practice as consulting civil engineers. During the war he was officer in charge of utilities at Camp Meade, with rank of major, and was responsible for practically the whole of the operation and maintenance of that large camp.

Mr. Whitman is a member of the American Society of Civil Engineers, American Water Works Association, American Public Health Association, New England Water Works Association, American Association of Engineers, and the Engineers' Club of Baltimore. His appointment has been a matter of very considerable gratification to friends and fellow engineering associates in Baltimore, where it is felt that considerable advantages will accrue from the presence of an engineer on the Public Service Commission.

A Correction

A. E. Hall has called attention to the fact that in the discussion of his paper in the February issue of Mechanical Engineering, page 101, the 54 to 60 in. dimensions referred to *circular* saws and that the 3-hp. and 4-hp. should have read 300-hp. and 400-hp.

Engineering and Industrial Standardization

Campaign Against Industrial Accidents

DURING 1921 the members of the National Safety Council are for the first time attempting a unified and intensive accident-prevention campaign. Formerly safety campaigns have been conducted independently in each of the 8000 member plants of the council, and although much has been accomplished by these scattered campaigns, there are still approximately 22,000 workers killed and 600,000 injured in industrial accidents each year.

The plan announced at the headquarters of the council in Chicago calls for a concentrated attack, through all available means, on a different hazard each month. Thus during January, in approximately 8000 industrial plants, mines, railroads and other public utilities throughout the country, a special campaign was conducted against ladder accidents. The February campaign was against neglect of minor injuries and infections arising therefrom, and the March campaign dealt with unsafe clothing. The campaigns announced for the other months are as follows: April, horse play; May, hand-tool hazards; June, standing or sitting in dangerous places; July, machinery hazards; August, inattention; September, fire; October, health hazards; November, careless handling of materials; and December, eye injuries.

Safety Code for Logging and Sawmill Machinery

For a number of months the Bureau of Standards, at the request of the American Engineering Standards Committee, has been organizing a Sectional Committee to formulate a safety code for logging and sawmill machinery. The personnel so far determined is as follows:

Name and Address	Association, Society or Firm Represented
Manufacturers' Organizations:	
W. Graham Cole, director of Safety and Industrial Relations	Southern Pine Association
Frank H. Lamb, president Wynooche Timber Company	Pacific Logging Congress
Dr. Wilson Compton, manager	National Lumber Manufacturers Association
....	West Coast Lumber Association
Individual Manufacturers:	
Kenneth Rushton, chief engineer	Baldwin Locomotive Works
W. G. Hagmier	Allis-Chalmers Company
J. S. Reid, president	Clark Brothers Company
State Authorities:	
H. M. Wolflin, Cal.	International Association of Industrial Accident Boards and Commissions
James C. Cronin, Pa.	
Richard J. Cullen, N. Y.	
C. H. Younger, Wash.	
R. A. McA. Keown, Wis.	
C. H. Gram, Ore.	
Government Bodies:	
Col. W. B. Greeley, Forester	U. S. Forest Service
E. H. Finlayson	Canadian Forest Service
E. B. Rosa	Bureau of Standards
M. G. Lloyd	
J. A. Dickinson	
Safety Engineering Organizations:	
Joseph H. Dickinson, Lidgerwood Manufacturing Company	American Society of Mechanical Engineers
C. W. Price, general manager	National Safety Council
Carl O. Hero, safety engineer, Lumber Mutual Casualty Insurance Company	American Society of Safety Engineers
Insurance Organizations:	
W. H. Cameron, secretary-treasurer	Workmen's Compensation Service Bureau
H. F. Richardson	National Council on Workmen's Compensation Insurance
Carl O. Hero, safety engineer, Lumber Mutual Casualty Insurance Company	National Association of Mutual Casualty Companies
Civic Associations:	
P. S. Risdale, secretary	American Forestry Association
Organized Labor:	
....	International Union of Timber Workers
Dr. Thorfinn Tharaldsen	Loyal Legion of Loggers and Lumbermen
Professional Societies:	
Prof. E. T. Clark, University of Washington	Society of American Foresters

Individual Experts:

Major Swift Berry, Timber Appraisal Section, U. S. Treasury Department
A. R. Lawrence, manager, Virginia State Rating Board
John H. Foster, N. H. State Forester
Robert Stanley, safety engineer, Parker-Young Co., Lincoln, N. H.
W. D. Scruggs, efficiency and safety engineer, Great Southern Pine Company, Bogalusa, La.
David Van Schaack, director, Bureau of Inspection and Accident Prevention, Aetna Life Insurance Co.

Safety Code for the Protection of Head and Eyes

Attention is called to a new publication of the Bureau of Standards, Handbook No. 2, entitled National Safety Code for the Protection of the Head and Eyes of Industrial Workers. This is a set of rules designed to give mechanical and optical protection to the eyes of workers in certain occupations which involve an eye hazard. The rules have been worked up in coöperation with outside conferees representing all points of view and especially with the assistance of an Advisory Committee which has approved the draft of the rules.

A copy of this code may be obtained by addressing the Bureau of Standards, Washington, D. C. If desired in quantity they may be obtained at a small charge from the Superintendent of Documents, Government Printing Office, Washington, D. C.

Industrial Lighting Code

At the March 6, 1920 meeting of the American Engineering Standards Committee the Illuminating Engineering Society was requested to form a Sectional Committee for the development of an Industrial Lighting Code and to assume sponsorship therefor. This society accepted the responsibility and has submitted the names of the members of the Sectional Committee to the A. E. S. C. The interests included in this Committee and the number of representatives assigned to each are as follows: state commissions (1), gas and electric companies (3), insurance interests (2), federal bodies (2), other general interests (3), manufacturers of lamps (2), and consulting engineers (3).

The members of the Sectional Committee are: L. B. Marks (Chairman), W. T. Blackwell, W. F. Little, R. E. Simpson, G. H. Stickney, W. J. Serrill, Prof. C. E. Clewell, Dr. Louis Bell, Dr. A. S. McAllister, G. B. Regar, Dr. M. G. Lloyd, Dr. Thomas C. Eipper, C. L. Law, W. D. Keefer, W. H. Cameron, and Dr. J. W. Schereschewsky.

Copper Specifications

The American Society for Testing Materials has submitted the following copper specifications to the American Engineering Standards Committee for approval:

Specifications for Soft or Annealed Copper Wire (B3–15).
Specifications for Lake Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars (B4–13).
Specifications for Electrolytic Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars (B5–13).
Methods for Battery Assay of Copper (B34–20).

Specifications B3–15, B4–13 and B5–12 may be found in the 1918 volume, and Specifications B34–20 in the 1920 volume of A. S. T. M. Standards. Copies of these may also be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York.

News of Other Societies

American Institute of Mining and Metallurgical Engineers

Annual meeting in New York, February 14–17. Iron and steel topics were extensively discussed. Two sessions were held on the breakage and steel treatment of drill steel, at which Benjamin F. Tillson, of the New Jersey Zinc Co., Francis B. Foley, of the Bureau of Mines, and Frank H. Kingdon, of Sullivan Machinery Co., presented papers dealing with the mechanics of failure of materials, and C. W. Burrows, of The Dorr Co., an illustrated report of an investigation on the fatigue of drill steel by magnetic survey and magnetic analysis. The discussion led to a resolution that the Institute establish a board in coöperation with other engineering societies and Government agencies to investigate the breakage and heat treatment of rock-drill steel and other steels subjected to similar stresses. This resolution was passed unanimously and will go to the board of directors for action. Two other sessions were held on iron and steel at which questions dealing with the manufacture and metallurgy of these metals were taken up. Some of the papers presented were: Static and Dynamic Tension Tests on Nickel Steel, by J. J. Thomas and J. H. Nead; Measurement of Blast-Furnace Gas, by D. L. Ward and R. S. Reed; Importance of Hardness of Blast-Furnace Coke, by Owen R. Rice; Manufacture of Ferromanganese in the Electric Furnace, by Robert M. Keeney and Jay Lonergan; Electric Furnace in the Iron Foundry, by Richard Moldenke; Surface Changes of Carbon Steels Heated in Vacuo, by E. H. Hemingway and G. R. Ensminger; and Molybdenum Steels, by John A. Mathews.

One entire session and parts of others were devoted to industrial relations. Among the papers presented were one on the Hiring and Placing of Men, by S. R. Rectanus, and another on Dust Ventilation Studies in Metal Mines, by D. Harrington. Sessions were held also on mining and milling, coal mining, nonferrous metallurgy, non-metallic minerals, and petroleum and gas. The list of papers presented at these sessions included: Relation of Air Pressure to Drilling Speed of Hammer Drills, by H. W. Seamon; Skip Hoisting for Coal Mines, by Andrews Allen and J. A. Garcia; Steel Chimneys and Their Linings in Copper Smelting Plants, by A. G. McGregor; By-Product Expansion in the Non-metallic Mineral Industries, by Oliver Bowles; and Effect of Temperature, Deformation, Grain Size, and Rate of Loading on the Mechanical Properties of Metals, by W. P. Sykes.

The papers by J. J. Thomas and J. H. Nead, H. W. Seamon, and W. P. Sykes are abstracted in the Survey Section in this issue.

At the banquet, Herbert Hoover, retiring president, delivered a brief address in which he reviewed the activities of the Institute during the past year. Edwin Ludlow, New York, the incoming president, spoke on the present labor conditions in the United States.

American Institute of Electrical Engineers

Annual meeting in New York, February 16, 17 and 18. President A. W. Berresford, in his address, reviewed the role of the engineer in modern civilization, calling attention to the rapid growth in magnitude of modern enterprises and the increasing application of science to all phases of life. The complicated civilization of the present day exhibits the process of association at its maximum and the engineer is being forced more and more into closer coöperation with his professional brothers. The day has past when he can grapple alone with the engineering problems of the times. They must now be solved by the profession as a whole, and herein lies the secret of the growth of engineering societies, which represent the concrete answer to the call for coöperation. At the same time, the spirit of association inevitably fosters the substitution for the motive of private interest the noble purpose of unselfish public service.

A notable feature of the meeting was the presentation of the Edison medal to Dr. Michael I. Pupin of Columbia University, "for work in mathematical physics and its application to the electrical transmission of intelligence." Upon receiving the medal, Dr. Pupin gave an address on Wave Transmission, in which he described some of his early experiences in Serbia and various incidents of his life and education leading up to his telephonic inventions. Numerous papers dealing with electrical subjects were presented at the technical sessions.

Taylor Society

Meeting at Springfield, Mass., February 24, 25, and 26. Professor Irving Fisher, of Yale University, explained how the instability of the dollar interferes with efficient industrial management, inasmuch as changes from prosperity to depression cause uncertainty and restriction of management activities. The committee on sales quota of the sales management section of the society submitted a preliminary report. A "sales quota" is a predetermined amount of business to be obtained in a given period by the sales department as a whole, by any branch of the department, by any individual salesman, in the entire country or in any state, county, city, sales district or subdivision of these. The determination of quotas, their apportionment and the results of the system were explained in detail. Meyer Bloomfield, in a paper entitled The Development of our Conception of the Function of Personal Administration, surveyed the progress in industrial management during the period from 1910 to the present year. Symposia were held on storekeeping, planning, layout and standardization of equipment, and analysis and standardization of manufacturing processes.

Engineering Institute of Canada

Annual meeting at Toronto, February 1, 2 and 3. Considerable attention was given to the proposed legislation for the registration of engineers in Canada. Through the efforts of the Institute registration laws have been adopted in each of the Canadian provinces, except Saskatchewan, Prince Edward Island, and Ontario. Work is well under way in these provinces, however, toward the successful passage of such legislation. The committee on international relations reported that arrangements had been completed with The American Society of Mechanical Engineers for an indefinite term and with the American Institute of Mining and Metallurgical Engineers for one year, whereby these societies and the Canadian Institute will mutually exchange privileges of publications; that is, any member of these American societies may obtain the publications of the Institute at the same price as that paid by the members of the latter organization, and vice versa.

National Machine Tool Builders' Association

Meeting at Cleveland, February 24, 25 and 26. Cost accounting of machine-tool plants was the chief topic of discussion. A report by Scovell, Wellington and Co. outlined a plan for standard methods of cost accounting which included such items as interest on invested capital, rent on buildings, cost of drawings, patterns, jigs and fixtures, cost of idleness, normal burden and unearned burden, and other points necessary to know total costs. Fred A. Geier showed by figures compiled from 70 important companies for the ten years prior to 1913 that the net returns averaged 9 per cent on the invested capital. Since that period, careful estimates place the net returns at $10^1/_2$ per cent. E. J. Kearney recommended the use of the budget system for recording expenses and keeping them within the proper limit. Ernest F. DuBrul outlined a program for the association to undertake, in coöperation with The American Society of Mechanical Engineers and other technical societies, along such lines as the standardization of machine tools and the organization of industrial research.

American Boiler Manufacturers' Association

Meeting at Cleveland, February 22. Committee reports on standard specifications for setting return-tubular and water-tube boilers were presented. Charles E. Gorton, chairman of the Uniform Boiler Law Society, reported on the recent Detroit meeting of the National Board of Boiler and Pressure Vessel Inspectors, which resulted in the formulation of valuable plans for bringing about the simplification of the stamping and registration of boilers, the examination and certification of inspectors, and the uniform interpretation of the Boiler Code. Provision was made for closer coöperation with the Boiler Code Committee of The American Society of Mechanical Engineers in the interpretation and revision of the Code and also as to tolerances in its enforcement.

LIBRARY NOTES AND BOOK REVIEWS

THE AIRPLANE. By Frederick Bedell. D. Van Nostrand Co., New York, 1920. Cloth, 6 × 9 in., 257 pp., frontispiece, diagrams, $3.

The first six chapters of this volume contain, in revised form, the material previously published under the titles Airplane Characteristics and The Air Propeller. Seven additional chapters discuss problems of flight, performance and stability. The author's aim has been to present a well-rounded introductory treatment simple in form, but reasonably complete and accurate.

AMERICAN LUBRICANTS FROM THE STANDPOINT OF THE CONSUMER. By L. B. Lockhart. Second edition, revised and enlarged. The Chemical Publishing Co., Easton, Pa., 1920. Cloth, 6 × 9 in., 341 pp., illus., tables, $4.

This book is offered to buyers and users of lubricants as an aid in the intelligent selection of oils and greases. It describes the various commercial lubricants, explains the laws of friction, the conditions met in lubricating various classes of machinery and the methods used to satisfy them. Methods for chemical and physical tests are given, and specifications for oils and other lubricants for a great variety of purposes.

ASPHALTS AND ALLIED SUBSTANCES. By Herbert Abraham. Second edition, corrected. D. Van Nostrand Company, New York, 1920. Cloth, 6 × 9 in., 608 pp., illus., diagrams, tables, $6.

This is a comprehensive treatise for makers, sellers and users of asphalts, tars, pitches and their products. It includes the methods used for testing and analyzing raw and manufactured products, information on blending and compounding mixtures, general information on the scope of the use of bituminous materials and on their limitations, and the principles underlying the use of bituminous products for structural purposes. Topics which have been adequately presented in other books have been purposely subordinated to those concerning which little has hitherto been published.

CAMS, ELEMENTARY AND ADVANCED. By Franklin De Ronde Furman. John Wiley & Sons, Inc., New York, 1921. Cloth, 6 × 9 in., 234 pp., diagrams, $3.

The first five sections of this book appeared previously under the title, Elementary Cams. To these sections three have been added, giving a further development of the subject. The elementary portion gives a classification, an arrangement and a general method of solution of the well-known cams, and also a series of cam factors for base curves in common use. The advanced portion includes the development or use of the logarithmic, cube, circular, tangential and involute base curves, and the establishment of cam factors for those which have general ones.

DIE KOMPRESSIONS-KALTEMASCHINE. By W. Koeniger. R. Oldenbourg, Munich and Berlin, 1921. Paper, 6 × 9 in., 204 pp., plates, tables, diagrams, 30 M.

This book is based on an extensive investigation of sulphurous-acid refrigerating machines by its author. New views resulted, which contribute to a solution of the question why the "wet" process of compression is less efficient than the "dry," and which also led to new methods for the calculation of refrigerating machines. The book is intended for students of the theory of these machines and for designers, and includes both sulphurous-acid and ammonia machines.

ELEMENTARY DYNAMICS; a Text-Book for Engineers. By J. W. Landon. University Press, Cambridge, 1920. Cloth, 5 × 7 in., 246 pp., diagrams, $3.25.

The author of this textbook believes that many of the beginner's difficulties in grasping the fundamental principles of dynamics arise from an overemphasis of mathematics. This difficulty he attempts to avoid by emphasizing the physical ideas, whose meaning he explains partly by definition and description, but mainly by worked examples in which formulas are avoided as far as possible.

ELEMENTS OF MECHANISM. By Peter Schwamb, Allyne L. Merrill and Walter H. James. Third edition. John Wiley & Sons, Inc., New York, 1921. Cloth, 6 × 9 in., 372 pp., diagrams, $3.50.

After sixteen years this textbook appears in a thoroughly revised and expanded edition, embodying the changes suggested by its use for instruction at the Massachusetts Institute of Technology and other colleges. It is intended to provide a systematic, clear, and practical presentation of the subject, suited to the amount of time usually devoted to it in college courses.

ERTRAGREICHSTER AUSBAU VON WASSERKRAFTEN. By Dr. Leiner. R. Oldenbourg, Munich and Berlin, 1920. Paper, 8 × 11 in., 111 pp., diagrams, 40 M.

The author examines the principles which serve as a guide in estimating the probable financial returns from the utilization of a water power; then he studies the most advantageous method of development, depending upon the constancy or intermittency of the power, the possibility of using reservoirs, and similar factors.

GAGE DESIGN AND GAGE MAKING. By Erik Oberg and Franklin D. Jones. First edition, first printing. The Industrial Press, New York, 1920. Cloth, 6 × 9 in., 310 pp., illus., diagrams, $3.

Much, the authors state, has been published on manufacturing practice, but comparatively little on the design and making of the gages used to control manufacturing processes and insure interchangeability in finished parts. Their book is intended to present the principles upon which gage design depends, and to describe the methods of manufacturing, measuring and testing gages.

HYDRO-ELECTRIC DEVELOPMENT. By J. W. Meares. Sir Isaac Pitman & Sons, Ltd. (Pitman's technical primer series.) 90 pp., front., illus., 4 × 6 in., boards, $1.

This little primer, based on the author's experience, aims to set down in logical order the points which require attention in the discovery, reconnaissance and final design of a hydroelectric scheme. It is confined strictly to the hydraulic aspect of the problem, omitting electrical questions and the practical details of plant construction.

KUGELLAGER UND WALZENLAGER IN THEORIE UND PRAXIS. By Paul Haupt. R. Oldenbourg, Munich and Berlin, 1920. Paper, 6 × 9 in., 199 pp., tables, diagrams, 18 M.

This work is a summary and extension of the scattered literature on bearings with rolling friction. Besides a theoretical discussion of the laws underlying the construction of ball and roller bearings, current practice is described, and the commercial types are examined critically.

PERSONAL RECOLLECTIONS OF ANDREW CARNEGIE. By Frederick Lynch. Fleming H. Revell Co., New York. Cloth, 6 × 8 in., 184 pp., portrait, $1.50.

Dr. Lynch's reminiscences cover a phase of Mr. Carnegie's activities that is not so widely known as his beneficences. His love of poetry and music, his religious opinions, interest in international peace, his views on education and similar topics, are set forth as he gave them to his friends.

PROPERTIES OF STEAM AND THERMODYNAMIC THEORY OF TURBINES. B, H. L. Callendar. Longmans, Green & Co., New York, 1920. Cloth 6 × 9 in., 531 pp., diagrams, tables, $14.

This work gives a connected account of the conclusions resulting from the author's extended experimental and theoretical investigations of the problems depending primarily on the properties of steam. It is therefore intended to supplement treatises written from an engineering standpoint, by presenting the thermodynamical aspect of the problem. The book explains the origin of the author's equations for steam, shows how well his theory has fitted with subsequent work, and how his equations and tables may best be applied to more recent developments. A considerable portion deals with the thermodynamical theory of turbines, and here some new methods are introduced which the author believes will be useful to engineers. The book includes his steam tables.

THE ENGINEERING INDEX

(Registered U. S. Patent Off.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ABRASIVE WHEELS

Manufacture. Manufacturing Abrasive Wheels. Eng. Production, vol. 2, no. 16, Jan. 20, 1921, pp. 82–88, 14 figs. Methods of Universal Grinding Wheel Co., England.

ACCIDENTS

Dust Explosions. Some Electrical Causes of Dust Explosions, David J. Price. Elec. Rev. (Chicago), vol. 78, no. 5, Jan. 29, 1921, pp. 179–181, 5 figs. Results of investigations of explosions and fires attributed to electricity at Bur. of Chemistry, U. S. Dept. of Agriculture. Menace of static electricity to grain-threshing and cotton-mill operations.

The Cause and Prevention of Dust Explosions (Ueber die Entstehung von Staubexplosionen und ihre Verhütung), H. Weinmann. Zeit. für das Berg-, Hütten- u. Salinenwesen, vol. 68, no. 3, 1920, pp. 100–114, 2 figs. Results of investigations carried out by author to determine whether disastrous explosions which occurred in a German sugar factory were the result of pure sugar-dust explosions or of such explosions in conjunction with other gases.

AERONAUTICAL INSTRUMENTS

Speed Recorder. A Manometer for Recording Flight Speeds (Ein Manometer zur Aufzeichnung von Fluggeschwindigkeiten), C. Wieselsberger. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 1, Jan. 15, 1921, pp. 4–6, 4 figs. Details of instrument constructed in the workshop of the Göttinger aerodynamic testing station, which is said to have shown good results in trial flights.

Two-Needle. Two-Needle Aeronautical Instruments (Appareils de bord à deux aiguilles), M. Dugit. Vie technique & industrielle, vol. 2, no. 16, Jan. 1921, pp. 323–327, 4 figs. Details of construction and uses in aerial navigation.

Uses. Aeronautic Instruments, Charles E. Mendenhall. Aerial Age, vol. 12, no. 20, Jan. 24, 1921, pp. 512–515, 5 figs. Classification of instruments and methods of using.

AEROPLANE ENGINES

Clearance-Volume Measurements. Instrument for Measuring Engine Clearance Volumes, S. W. Sparrow. Aerial Age, vol. 12, no. 23, Feb. 14, 1921, pp. 583–584, 6 figs. Instrument designed and constructed under direction of Automotive Power Plants Section of Bur. of Standards. Technical note of Nat. Advisory Committee for Aeronautics.

Near-Diesel. A Near-Diesel Engine for the Airplane, Harold F. Blanchard. Sci. Am., vol. 124, no. 4, Jan. 22, 1921, pp. 65 and 79, 3 figs. Engine designed by Prof. Junkers. Advantages claimed are low weight per horsepower, increased reliability, higher fuel economy, greater simplicity, safety against fire, and perfect balance.

Superchargers. Turbine-Driven Aeroplane Engine Superchargers for Flight at High Altitudes (Les surpresseurs pour moteurs d'aéroplanes à commande par turbine, pour le vol aux hautes altitudes). Génie Civil, vol. 78, no. 3, Jan. 15, 1921, pp. 55–56, 2 figs. Economical advantages of supercharging engine at high altitudes. Supercharger constructed by Gen. Elec. Co.

Wright. New Wright Aeronautic Engine Succeeds the Hispano-Suiza, A. Ludlow Clayden. Automotive Industries, vol. 44, no. 4, Jan. 27, 1921, pp. 154–156, 4 figs. Machine retains steel sleeve and combination valve stem and tappet, but embodies many changes originally developed by Wright Co., including better cooling and simplified lubrication systems. New magneto mounting provided.

Turbo-Compressors for. The Rateau Turbo-Compressor, H. M. Buckwald. Aviation, vol. 10, no. 3, Jan. 17, 1921, pp. 73–76, 10 figs. Details of construction and results of tests.

AEROPLANE PROPELLERS

All-Metal. The Leitner-Watts All-Metal Propeller. Aerial Age, vol. 12, no. 22, Feb. 7, 1921, pp. 559–560, 3 figs. Structural details, and records of tests.

Reversible Pitch. Hart Reversible Pitch Propeller. Aviation, vol. 10, no. 3, Jan. 17, 1921, pp. 79–80, 6 figs. Experiments of Engineering Division, U. S. Army Air Service.

Variable-Pitch. Parker Variable Pitch Air Screw, Billy Parker. Aerial Age, vol. 12, no. 24, Feb. 21, 1921, pp. 610–711, 2 figs. As machine climbs into higher altitudes and more rarified air is encountered, blades automatically increase their pitch so that constant load is kept on motor.

AEROPLANES

Aerofoils. See Wings.

Design. Aeronautics in 1920—I. Engr., vol. 131, no. 3393, Jan. 7, 1921, pp. 5–7, 9 figs. partly on 2 supp. plates. Survey of developments in aeroplane design.

Aeroplane Design, F. S. Barnwell. Aeronautics vol. 20, no. 379, Jan. 20, 1921, pp. 49–50. Table of airscrews of not more than 8 ft. diameter to absorb 1 hp. (Concluded.) Paper read before Cambridge University Aeronautical Soc.

Fuselage Construction. The Monocoque Fuselage, Lester D. Seymour. Aviation, vol. 10, no. 7, Feb. 14, 1921, pp. 203 and 206, 6 figs. Structural details of one-piece monocoque fuselage invented in France. Advantages of this type of construction.

Passenger. The 1000-Hp. Passenger Monoplane of the Zeppelin Works, Staaken (Das 1000 Ps-Verkehrsflugzeug der Zeppelin-Werke, Staaken), A. K. Rohrbach. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no 1, Jan. 15, 1921, pp. 1–4, 8 figs. Specifications: Engine, four 260 hp. Maybach engines; span, 31 m.; aerofoil surface, 106 sq. m.; gliding speed, 130 km. per hr.; carrying capacity, 18 passengers and 2 pilots; fuel-storage capacity, 6 hl. Duralumin is used for aerofoil, fuselage and empennage.

Stabilizers. The Automatic Control of Aeroplanes. Engineering, vol. 111, no. 2876, Feb. 11, 1921, pp. 178–179, 3 figs. Aveline automatic control apparatus for aeroplanes.

The Aveline "Automatic Pilot." Flight, vol. 13, no. 5, Feb. 3, 1921, pp. 73–75, 7 figs. Patented stabilizer employing inclinometer in which fluid is mercury. Machine is based on slight modifications of pendulum principle and is partly electric, partly pneumatic and partly aerodynamic.

Testing, Railway for. A Railway for Testing Full Size Aeroplanes. II. Bendemann. Aeronautics, vol. 20, no. 380, Jan. 27, 1921, pp. 64–65, 5 figs. Testing tower placed on modification of railway truck which is pulled along by locomotive. On top of tower is placed full-sized aeroplane to be tested. Paper read before German Aeronautical Soc.

Wings. A German Rival of the Handley-Page Wing. Aviation, vol. 10, no. 6, Feb. 7, 1921, p. 179, 1 fig. Wing with peculiarly shaped passages which are said to increase both pressure on under side and suction on upper side. Translated from Flugsport.

The Action of Aeroplane Wings (Die Wirkungsweise der Tragflächen), H. Lorenz. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 1, Jan. 1, 1921, pp. 8–11, 9 figs. Deals with pressure of wings, and the influence of inclination and camber suface.

The Glenn Martin High-Lift Wing. Aerial Age, vol. 12, no. 23, Feb. 14, 1921, p. 585, 1 fig. It is said that Glenn Martin Co. of Cleveland have designed aeroplane wing which can lift greater weight per sq. ft. than any other known type. No description of wing is given.

The Internally Trussed Wing, William B. Stout. Aviation, vol. 10, no. 7, Feb. 14, 1921, p. 200. Comparative study of American and German designs.

The Lachmann Aerofoil. Aerial Age, vol. 12, no. 22, Feb. 7, 1921, p. 560, 2 figs. German design consisting of several separate staggered elements arranged in form of Venetian blind. Translated from Flugsport.

Torsion of Wing Trusses at Diving Speeds, Roy G. Miller. Nat. Advisory Committee for Aeronautics, report no. 104, 1920, 8 pp. 4 figs. Suggestions in regard to methods for analyzing stresses in wing truss in vertical dive at limiting velocity.

[See also SEAPLANES; WIND TUNNELS.]

AIR COMPRESSORS

Membrane. The Membrane Compressor (Compresseur à membrane), H. Corblin. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 1, Jan. 3, 1921, pp. 46–48, 1 fig. Air or gas is compressed by alternative movements of circular membrane held rigidly at edges between two conically shaped hollow disks. Above one of these disks a piston forces air or liquid into and out of disk. Air is compressed by movements of membrane operating suitable valves in other disk.

AIR FILTERS

Radio Type. Air Filters (Luftfilter), K. Reichardt Oel- u. Gasmaschine, vol. 17, no. 12, Dec. 1920, pp. 185–186, 2 figs. Describes the Radio air filter equipped with a chamber in which the admitted air is conducted over a large perforated surface and distributed, after which it passes into the filter proper which is filled with metal rings having lateral openings. The dust-absorbing capacity of filter is said to be much greater than that of cloth or wire filters.

AIR SERVICE, UNITED STATES

United Air Force. United Air Force—Pro and Con. Aviation, vol. 10, no. 7, Feb. 14, 1921, pp. 196–198. Arguments for and against army and navy united air force. (Concluded.)

AIRCRAFT

Anchorage. The Universal Aircraft Anchorage. Flying, vol. 10, no. 1, Feb. 1921, pp. 22–24, 5 figs.

Dock for landing, mooring and storing of airships and aeroplane, invented by E. S. Ullman.

Submarine vs. Aircraft v. Submarines, L. H. Strain. Flight, vol. 13, no. 3, Jan. 20, 1921, pp. 46–48. Their comparative value as weapons of war studied from records of their respective applications in last war. Writer believes that if air force is developed extensively there need not be any fear of the submarine in future campaigns. Paper read before Royal Aeronautical Soc.

AIRCRAFT CONSTRUCTION MATERIALS

Plywood. See PLYWOOD.

Steels. British Standard Schedule of Cold Worked Steels for Aircraft. British Eng. Standards Assn., no. 112, Nov. 1920, 15 pp., 2 figs. Schedule of seven cold-worked steels in form of black bars. Chemical composition, heat treatment and mechanical properties are specified.

British Standard Schedule of Sheet Steels for Aircraft. British Eng. Standards Assn., no. 113, Nov. 1920, 12 pp., 3 figs. Schedule of three sheet steels. Chemical composition, heat treatment and mechanical properties are specified.

British Standard Schedule of Valve and Valve Spring Steels for Aircraft. British Eng. Standards Assn., no. 114, Nov. 1920, 17 pp., 7 figs. Schedule of three valve steels and two valve-spring steels for aircraft engines. Chemical composition, heat treatment and mechanical properties are specified for steel in form of bars, forgings and drop forgings.

British Standard Schedule of Wrought Steels for Aircraft. British Eng. Standards Assn., no. 111, Nov. 1920, 27 pp., 9 figs. Schedule of fourteen wrought steels in form of bars, billets, forgings and drop forgings. Chemical composition, heat treatment and mechanical properties are specified.

AIRSHIPS

Rigid. Speed and Endurance of the Rigid Airship. E. H. Lewitt. Aeronautics, vol. 20, no. 379, Jan. 20, 1921, pp. 43–44, 2 figs. Graphs showing variation between speed, horsepower and capacity. (To be continued.)

Zeppelin. The Zeppelin Airships, L. 64 and L. 71, George Whale. Aeronautics, vol. 20, no. 377, Jan. 6, 1921, p. 9. Classification and description of types.

ALCOHOL

Peat as Source of. See PEAT, Gasoline from.

[See also AUTOMOBILE FUELS, Alcohol.]

ALLOY STEELS

Electrometric Analyses. The Electrometric Analyses of Special Steels (Analyses électrométriques des aciers spéciaux). Industrie Electrique, vol. 30, no. 686, Jan. 25, 1921, pp. 33–36, 5 figs. Industrial apparatus for determining chromium, vanadium, and manganese.

Uranium Steel. Investigates Uranium Alloy Steel, E. Polushkin. Iron Trade Rev., vol. 68, no. 6, Feb. 10, 1921, pp. 413–417, 6 figs. In medium-carbon steel uranium increases elastic limit and resistance to rupture without affecting ductility. No unusual results were obtained than could not be had with other special steels. Translated from Revue de Métallurgie.

ALUMINUM

Castings. Analyze Loss in Aluminum Shops—IV, Robert J. Anderson. Foundry, vol. 49, no. 3, Feb. 1, 1921, pp. 104–111. Tables showing casting losses in various foundries on different castings. Percentages of losses from enumerated causes are indicated in case and comparisons are made.

ALUMINUM ALLOYS

Aluminum-Iron. Influence of Iron on the Mechanical Properties of Chemical Aluminum (L'influence du fer sur les propriétés mécaniques de l'aluminium brut de coulée), Léon Guillet and Albert Portvin. Revue de Métallurgie, vol. 17, no. 11, Nov. 1920, pp. 753–756, 4 figs. Addition of iron to chemical aluminum was found to increase hardening and to diminish ductility. With 4 per cent iron alloy is not capable of plastic deformation.

Castings. Castings of Light Aluminum Alloys, Robert J. Anderson. Iron Age, vol. 107, no. 7, Feb. 17, 1921, pp. 433–436, 15 figs. Value of macroscopic examination in foundry practice. Its correlation with microstructure. Methods used and typical structures.

Copper-Aluminum. Mechanism of Solidification of a Copper-Aluminum Alloy, Junius David Edwards. Chem. & Metallurgical Eng., vol. 24, no. 5, Feb. 2, 1921, pp. 217–220, 5 figs. Study of piping, segregation and mechanism of solidification of Cu-Al alloys, especially no. 12 containing 8 per cent aluminum, by means of precision measurements on density at various high temperatures.

AMMONIA

Manufacture. Artificial Ammonia, Jacques Boyer. Sci. Am., vol. 124, no. 6, Feb. 5, 1921, pp. 110, 4 figs. Claude process in successful operation in France.

British Neutral Sulphate Process, E. V. Evans. Gas Age, vol. 47, no. 2, Jan. 25, 1921, pp. 44–46. Methods of neutralizing free acid by ammonia gas at South Metropolitan Gas Co., London. Paper read before Southern District Assn. of Gas Engrs. & Managers.

Saturated, Tables for. Temperature and Pressure Tables for Saturated Ammonia. Power, vol. 53, no. 3, Jan. 18, 1921, pp. 96–99. Tentative tables prepared by U. S. Bur. of Standards.

Synthetic. Manufacture of Synthetic Ammonia at Oppau, Germany—I. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 305–308, 7 figs. Principle of process. Manufacture of producer gas and water gas used in process. Purification of gas mixture. Catalytic oxidation of carbon monoxide. Elimination of carbon dioxide and carbon monoxide. Translated from Technique Moderne.

AMMONIA ABSORPTION REFRIGERATING SYSTEM

Non-Condensible Gases in. Causes and Prevention of the Formation of Noncondensible Gases in Ammonia Absorption Refrigeration Machines. E. C. McKelvy and Aaron Isaacs. Technologic Papers, Bur. of Standards, Dept. of Commerce, no. 180, Oct. 25, 1920, 10 pp., 1 fig. Method for quantitative estimation of carbon dioxide in ammonia is also given.

APPRENTICES, TRAINING OF

Draftsmen. How to Train Drafting Apprentices, S. E. Ferry. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 95–97. Outline of two-year training course.

Methods. Programs of Apprenticeship and Special Training in Representative Corporations, J. V. L. Morris. Am. Mach., vol. 54, no. 6, Feb. 10, 1921, pp. 230–232, 4 figs. Practice of Brown & Sharpe Mfg. Co., Providence, R. I. Apprentice training has gone on for 70 years. Present school holds classes during working hours. Coöperative students also are employed.

Programs of Apprenticeship and Special Training in Representative Corporations, J. V. L. Morris. Am. Mach., vol. 54, no. 8, Feb. 24, 1921, pp. 310–312, 3 figs. Practice of Bethlehem Shipbuilding Corp., Quincy, Mass. Sub-foremen are trained to act as instructors for new men.

School Education. Engineering Education, Charles C. Garrard. Eng. Rev., vol. 34, no. 7, Jan. 1921, pp. 175–178 and 180. Report of City of Birmingham Education Committee on school education of apprentices.

Textile Mills. Standardized Training of Textile Apprentices, Eugene Scepesi. Textile World, vol. 59, no. 6, Feb. 5, 1921, pp. 193 and 295, 298, 305 and 309, 10 figs. Uniform methods of industrial education, a means for reducing waste and loss accruing under present system.

AUTOMOBILE ENGINES

Abell. A High Speed Engine with Positively Operated Valves. Automotive Industries, vol. 44, no. 4, Jan. 27, 1921, pp. 157–159, 4 figs. Abell design in which but one poppet valve per cylinder is used, this being put in communication alternately with inlet and exhaust ports by rotary distributor placed lengthwise of cylinder head casting. Yoked rocker levers have two rollers in contact with opposit sides of cam. Cooling of valves by incoming charge makes it possible to use higher compression without knock.

Air-Cooled. A Revolving Air-Cooled Engine. Automotive Industries, vol. 44, no. 5, Feb. 3, 1921, pp. 219–220, 1 fig. Has cylinder axes parallel to axis of rotation and utilizes wobbling-plate principle. Is of four cycle type but has planetary gear so arranged that engine makes one revolution for two revolutions of plate, thus combining high piston speed with low rotative speed. Single sleeve valve of cast iron is employed in each of five aluminum cylinders.

Air-Temperature Regulation. Air-Temperature Regulation Effects on Fuel Economy, Reuben E. Fielder. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 119–122, 7 figs. Tests conducted by Fifth Avenue Coach Co. of New York City to study temperature of air entering into cylinder.

Carburetors. See CARBURETORS.

Design. Fuel Problem in Relation to Engineering Viewpoint, A. L. Nelson. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 101–115, 33 figs. Account of extensive tests conducted with view of studying effect of engine design and correlation of results obtained for undertaking research of fuel problem.

Relation Between Principal Characteristics of an Automobile Engine (Relations entre les principales données constructives d'un moteur), Raymond Bricout. Technique automobile et aérienne, vol. 11, no. 111, 1920, p. 127, 1 fig. Graphs showing relation between cylinder diameter, piston stroke r.p.m., etc.

Eight-Cylinder, Balancing. Balancing of Eight-Cylinder Automobile Engine, and Order of Firing of Cylinders (Etude du moteur à huit cylindres en ligne au point de vue équilibrage et ordre du travail des cylindres). Technique automobile et aérienne, vol. 11, no. 111, 1920, pp. 97–125, 31 figs. Diagrams indicating stresses in crankshaft at various stages of rotation, computation of maxima stresses formulas for inertia forces, etc.

Engine Speed and Air Speed. Diagram Giving the Velocity of an Automobile in Terms of the R.P.M. of a Motor (Abaque donnant la vitesse d'une voiture en fonction de la vitesse de rotation du moteur), R. Bricout. Technique automobile et aérienne, vol. 11, no. 111, 1920, p. 126, 1 fig.

Hot-Spot Manifold. The Volatility of Internal-Combustion Engine Gasoline, Frank A. Howard. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 145–148, 1 fig. Argument for further development, improvement and wider use of hot-spot manifold of automotive engines.

AUTOMOBILE FUELS

Alcohol. Researches on Alcohol as a Fuel for Internal Combustion Engines. Harold B. Dixon. Automotive Industries, vol. 44, no. 5, Feb. 3, 1921, pp. 211–215. Basic data on vapor pressure, ignition temperature, movement of flame through explosive mixtures and detonation of vapor of alcohol, gasoline, benzol and various mixtures of two of these fuels. Authorization of standard alcohol mixtures to be used with present engines is urged.

Naphthalene. The Combustion of Naphthalene Solutions in Internal Combustion Engines. L. S. Palmer. Automobile Engr., vol. 11, no. 146, Jan. 1921, pp. 31–34, 6 figs. Naphthalene dissolved in benzole to strength of 15 per cent by weight said to form efficient fuel for ordinary gasoline engines.

Research. Notes on Current Fuel Research. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 31–134. Answers to circular letters sent to members of Soc. of Automotive Engrs., asking them method in which they were studying fuel problm and reasons for policy followed in their studies.

AUTOMOBILE INDUSTRY

Germany. The German Automobile and Aircraft Industries, Automobile Engr., vol. 11, no. 146, Jan. 1921, pp. 25–27. There have been no changes in principal designs. In contrast with England, France and Italy there is absence of Americanization in chassis design and construction.

AUTOMOBILES

American-Made. 1921 Passenger Automobiles Listed with Their Technical Specifications. Motor Age, vol. 39, no. 4, Jan. 27, 1921, pp. 78–81. Tabulated data of American-made automobiles with makes of principal parts, including engine, lubrication and ignition systems, etc.

Battery Charging. Electric Vehicle Charging Equipments, E. Austin. Automobile Engr., vol. 11, no. 146, Jan. 1921, pp. 22–24, 6 figs. Machine built by Lancashire Dynamo & Motor Co. for working on polyphase circuit.

Body Construction. Some Sheet Metal Body Work. Am. Mach., vol. 54, no. 8, Feb. 24, 1921, pp. 318–320, 6 figs. Operations involved in making metal bodies for Ford cars. Blanking, forming and finishing sheets.

Body Design. Style in Automobile Bodies, George J. Mercer. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 123–126, 1 fig. Prevailing body types and possible developments.

Brakes. Friction Metal for Brake Linings. Automotive Industries, vol. 44, no. 4, Jan. 27, 1921, p. 153, 1 fig. Adaptation of European practice facilitated by manufacture in this country of copper-lead alloy said to possess exceptional friction qualities. Tests with V-shape brake on truck promise well. Elimination of brake squeaking said to be effected. High friction coefficient claimed.

Brussels Show. The Brussels Stalon (Le salon de Bruxelles), H. Petit. Vie Automobile, vol. 16, no. 720, Dec. 25, 1920, pp. 476–481, 13 figs. Survey of exhibits. (To be continued.)

Chassis Design. Chassis Design for Fuel Economy, A. L. Putnam. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 167–168. Basis for research.

French. Automobile Production for 1921 (La production automobile pour 1921), Charle Faroux, Henri Petit and André Contet. Vie Automobile, vol. 16, no. 720, Dec. 25, 1920, pp. I-LXXIII, 120 figs. Particulars of types to be constructed during 1921 by leading French automobile works, including also projected designs of motorcycles and automobile accessories.

Friction Drive. Kelsey Friction-Driven Car is Announced. Automotive Manufacturer, vol. 42, no. 10, Jan. 1921, pp. 26–29, 3 figs. Friction drive said to effect loss of 13 and 25 per cent on high and low speeds respectively, as compared to 25 and 30 per cent equivalent for average gear drive.

Gradient Meter. The Tapley Gradient Meter. Autocar, vol. 46, no. 1316, Jan. 8, 1921, p. 54, 2 figs. Needle indicates on gradient scale steepness of hill.

New York Show. Some New Parts Seen at the New York Show, P. M. Heldt. Automotive Industries, vol. 44; no. 4, Jan. 27, 1921, pp. 160–161, 5 figs. Two new axles, one of which uses two cone clutches in place of differential, are shown. New flexible universal of laminated steel, automatic advance magneto coupling, and lubricating system for transmission universals and axle, are among developments.

Transmission Gears. Impact Stresses in the Transmission Gears of Automobiles (Sur les chocs dans les engrenages de changement de vitesse des automobiles), A. Petot. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 1, Jan. 3, 1921, pp. 42–44. Formulas for computing stresses.

AVIATION

City Ordinances. Aerial Ordinance for New York City. Flying, vol. 10, no. 1, Feb. 1921, p. 25. Ordinance governing air traffic over New York City.

Civil. Progress of British Civil Aviation. Aviation, vol. 10, no. 7, Feb. 14, 1921, pp. 207–208. Report of British Controller-General of Civil Aviation on progress of civil aviation covering six months period from April 1 to Sept. 30, 1920.

Commercial. European Recognition of the Possibilities of the Airplane for Commercial Uses, E. A. Dixie. Am. Mach., vol. 54, no. 6, Feb. 10, 1921, pp. 233–234, 2 figs. English daily papers publish meteorological reports. There are two lines of air buses between London and Paris.

The Design Requirements of Commercial Aviation, Grover C. Loening. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 135–144, 13 figs. Single-engined versus multi-engined planes. Desirable future developments.

Developments. Review of Aviation in 1920. Aviation, vol. 10, no. 3, Jan. 17, 1921, pp. 83-84. Prepared by Manufacturers' Aircraft Association.

Forest Fire Patrol. A Year of the Aerial Forest Fire Patrol. Flying, vol. 10, no. 1, Feb. 1921, pp. 13-16. Report submitted by air officer of headquarters ninth corps area at San Francisco.

B

BALANCING MACHINES

Turbine-Rotor. Martin's Rotor Balancing Machine. Elec. Rev. (Lond.), vol. 83. no. 2253, Jan. 28, 1921, pp. 101-102, 4 figs. Patented machine for balancing rotors without rotation.

BEARING METALS

Anti-Friction. Anti-Friction Bearing Metals. P. W. Priestley. Metal Industry (N. Y.), vol. 19, no. 2, Feb. 1921, pp. 66-67. Chemical, physical, and thermal review.

White-Metal. High-Temperature Properties of White-Metal Bearing Alloys, John R. Freeman, Jr. and R. W. Woodward. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 149-154 and 162, 8 figs. Preparation of alloys, and table of properties.

BELTING

Leather, Effect of Humidity on. Effect of Relative Humidity on Leather Belts, F. W. Roys. Can. Machy., vol. 25, no. 5, Feb. 3, 1921, pp. 76-78 and 98, 9 figs. Explanation of humidity, relative humidity, testing apparatus, atmospheric control, standard conditions and series of tests. Paper read before Nat. Assn. Leather Belting Manufacturers.

Rubber. Rubber in Mine and Mill, A. M. Oliver, Eng. & Min. Jl., vol. 111, no. 6, Feb. 5, 1921, pp. 258-262, 3 figs. Formulas for computing sizes and plies of belting.

BLAST FURNACES

Combustion Regulation. Regulation of the Combustion in Cupola Furnaces and of Working Process through Measurement of the Blast Capacities (Die Kontrolle der Verbrennung im Kuppelofen und des Arbeitsvorganges durch Windmengenmessung), H. Bansen. Stahl u. Eisen, vol. 41, no. 4, Jan. 27, 1921, pp. 114-115, 2 figs. Gives chart showing comparison of the analysis of flue gas taken from cupola furnace with the combustion curve of coke, and defines measurement of nozzle resistance.

Construction. New Blast Furnace Built at Midland. Blast Furnace & Steel Plant, vol. 9, no. 2, Feb. 1921, pp. 132-138, 1 fig. Construction of 600-ton furnace at Midland, Pa. Furnace stack is 92 ft. high with hearth 18 ft. diameter, stock line 16 ft. and bell 12 ft. diameter.

Developments in 1920. Blast Furnace Developments During 1920, Harvey W. Linhardt. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 20-22. Improvements in design, hot blast stoves, boiler plants, blowing engines, furnace appliances and gas cleaners.

Mechanical Equipment. Mechanical Equipment on Tapping Side of the Blast Furnace (Maschinenarbeit hinter dem Hochofen), F. W. Broy. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 3, Jan. 15, 1921, pp. 57-63, 15 figs. Calls attention to neglect up to present time of mechanical expedients on tapping side of blast furnace. Notes on difficult manual work on the casting beds insufficiency of the pig breakers; development of the pig hammers and charging cranes; high-capacity charging cranes; separation of the breaker and charging cranes. Diagrams showing utilization of the crane installation. Future problems.

Operation. Study of Coke Hardness, Owen R. Rice. Iron Trade Rev., vol. 68, no. 6, Feb. 10, 1921, pp. 423-426, 4 figs. Tests made in three stacks of Bethlehem Steel Co. to determine relation of furnace condition to coke hardness. (Abstract.) Paper read before Am. Inst. Min. & Metallurgical Engrs.

Sulphur Content of Charge. The Sulphur Content of an Iron Charge in Cupola-Furnace Melting Process with the First Tapping in Contrast to the Following (Der Schwefelgehalt einer Eisengattierung im Kupolofen-Schmelzprozess beim ersten Abstich gegenüber den folgenden), Paul Liebaldt. Giesserei-Zeitung, vol. 18, no. 1, Jan. 1, 1921, pp. 5-8. Tables giving results of a series of chemical and mechanical experimental investigations demonstrating that the first tapping does not show an enrichment of sulphur nor a greater silicon residue than the following. For special castings it is said to be advisable not to use the first tapping because in most cases it is too dull.

BLOWERS

Power Chart. Notes on the Calculation of Blower Systems, John L. Alden. Power, vol. 53, no. 5, Feb. 1, 1921, pp. 180-183, 2 figs. Power chart for air blowers, and friction chart for air piping.

BOILER EXPLOSIONS

Records. Forty Years of Boiler Explosions. Locomotive, vol. 33, no. 4, Oct. 1920, pp. 101-108, 8 figs. There have been in period 1880-1919 total of 14,281 explosions, 10,638 lives lost and 17,085 persons injured.

BOILER FEEDWATER

Treatment. Saving Money by Water Treatment, Paul M. LaBach. Ry. Maintenance Engr., vol. 17, no. 1, Jan. 1921, pp. 17-20, 3 figs. Water treating plants installed by Rock Island system, and results obtained.

BOILER OPERATION

Coal Saving. Coal-Saving in the Chemical Industry, David Brownlie. Pamphlet published by Brownlie & Green, England, 15 pp. Rules for scientific control of steam boiler plant based on records of performance of 60 typical steam boiler plants of chemical industry of Great Britain. Reprinted from Chem. Trade Jl. & Chem. Engr., Aug.-Sept 1920.

Feedwater Regulation. Scientific Boiler Feed Water Regulation, Roland Moeller. Jl. Am. Soc. Heat. & Vent Engrs., vol. 27, no. 1, Jan. 1921, pp. 19-24, 6 figs. Automatic mechanical device.

Firing. Influence Upon Boiler Economy of Continuous Firing of Highly Volatile Fuel Without Intervening Cleaning. A. B. Reck. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 1, Jan. 1921, pp. 1-5, 3 figs. Results of two tests with bituminous coal one made before and another after fourteen days of continuous firing with same fuel without intervening cleaning.

BOILERS

Bonecourt Gas-Fired. Recent Developments in Gas-Firing Steam Boilers, and in the Utilization of Waste Heat, on the "Bonecourt" System, W. Gregson. Proc. South Wales Inst. Engrs., vol. 36, no. 2, Jan. 21, 1921, pp. 279-314 and (discussion) pp. 488-508, 13 figs. Bonecourt boiler consists essentially of outer shell, forming boiler, fitted with longitudinal fire-tubes which carries special packing, mixture of gas and air being drawn through boiler either by natural draught or by suitably arranged suction fan.

Holdsworth. The Holdsworth Lancashire and Yorkshire Boilers. Practical Engr., vol. 63, no. 1767, Jan. 6, 1921, pp. 8-11, 2 figs. Comparison of two types.

Inspection. A National System for the Inspection and Registration of Steam Boilers. Power, vol. 53, no. 2, Jan. 11, 1921, pp. 58-61. Plea for adoption by all States of Boiler Code of Am. Soc. Mech. Engrs., which was formulated by committee composed of representatives of users, designers and manufacturers of boilers and boiler materials after numerous and exhaustive hearings in which representatives of every interest affected took part. This Boiler Code has been adopted as standard by Boiler Inspection Departments of 17 states.

Körting Universal. A New Boiler Adaptable to Use of Different Kinds of Fuel (Ein neuer Heizkessel für verschiedenartige Brennstoffe), Johannes Körting. Gesundheits-Ingenieur, vol. 43, no. 47, Nov. 20, 1920, pp. 554-556, 2 figs. Describes the Körting universal boiler for central heating constructed along lines of the cast-iron sectional boiler with the difference that the separate heating units are arranged, not back of, but alongside of each other. Its noteworthy features are pointed out and results of tests are given which confirm its feasibility.

Marine. See MARINE BOILERS.

Water Purification Chamber. Builds Water Purifier in Vertical Boiler. Iron Trade Rev., vol. 68, no. 4, Jan. 27, 1921, pp. 293, 1 fig. Locomotive crane boiler equipped with annular scale chamber placed between tubes and shell plate. Feedwater passes through scale chamber and attains temperature at which scale forming impurities are liberated from solution without chemicals.

BOILERS, WATER-TUBE

Mercantile Marine. Advantages of the Use of the Water-Tube Boiler in the Mercantile Marine, James Kemnal. North-East Coast Instn. of Engrs. & Shipbuilders, Advance paper, 9 pp. 8 figs. Advantages of water-tube boiler over cylindrical type.

BORING MACHINES

Horizontal. Recent Machine Tool Developments. Engineering, vol. 111, no. 2873, Jan. 21, 1921, pp. 66-69, 25 figs. partly on supp. plate. Horizontal boring machines.

BRAKES

Kunze-Knorr. The Standardization of Railroad Brakes (Zur Frage einer einheitlichen Eisenbahn-Bremse), C. Wetzel. Schweizerische Bauzeitung, vol. 77, no. 3, Jan. 13, 1921, pp. 29-33, 5 figs. Contains abstract of pamphlet describing and illustrating the Kunze-Knorr brake for freight trains. It is claimed that the Kunze-Knorr brake fulfills conditions required of a continuous freight-train brake as set up by the International Commission in 1909.

Shoe Design. Designing Brake Heads for Uniform Shoe Wear, H. M. P. Murphy. Ry. Mech. Engr., vol. 95, no. 2, Feb. 1921, pp. 107-108, 5 figs. Principle applicable to heads used on wheels revolving in one or both directions.

BRASS

Nickel. Nickel Brasses. Chem. & Mettallurgical Eng., vol. 24, no. 6, Feb. 9, 1921, pp. 261-265, 6 figs. Summary of work of Leon Guillet published in "Revue de Metallurgie" of 1913 and 1920 on important role played by nickel in manufacture of low-copper ternary brasses.

Ternary. Ternary Brasses. Chem. & Metallurgical Eng., vol. 24, no. 4, Jan. 26, 1921, pp. 177-178, 4 figs. Mathematical study of equilibrium diagram, and results of studies made by various investigators, notably L. Guillet in Revue de Métallurgie.

BROACHES

Manufacture. The Design and Manufacture of Broaches. Eng. Production, vol. 2, no. 17, Jan. 27, 1921, pp. 122-126, 3 figs. With special reference to parts having internal splines.

BUILDING CONSTRUCTION

Structural-Steel Standards. Construction Practice (Aus der Konstruktionspraxis), Rud. Kramer. Eisenbau, vol. 12, no. 1, Jan. 18, 1921, pp. 7-18, 10 figs. Writer points to the absence of generally applicable standards in structural steelwork and presents, as result of experience, tables for rivet diameters, distances from center of rivet to outside of angle, distances of rivet from edge of plate, pitch of rivets, lengths of angles, etc.

BUILDINGS

Steel-Frame. See ELECTRIC WELDING, Steel-Frame Buildings.

C

CAR AXLES

Design. Notes on Axle Design. Machy. (Lond.), vol. 17, no. 434, Jan. 20, 1921, pp. 494-495, 3 figs. Chart for determining centrifugal force exerted on car axles when turning a curve.

CAR WHEELS

Chilled - Iron. Chilled - Iron Car - Wheels — Their Manufacture, Properties and Uses (Les roues en fonte trempée leur fabrication, propriétés et usages), M. E. Polushkin. Revue de Métallurgie, vol. 17, no. 11, Nov. 1920, pp. 713-735, 20 figs. European and American practices contrasted. (To be continued.)

CARBURETORS

Asmo. Some Carburation Points, and a New Carburettor—The Asmo. Auto-Motor Jl., vol. 26, no. 2, Jan. 13, 1921, pp. 41-42, 5 figs. Instrument incorporates vacuum-feed fuel-supply.

Kerosene. The "Gaserator." Auto-Motor Jl., vol. 26, no. 1, Jan. 6, 1921, p. 20, 1 fig. Application of vaporization system of carbureting kerosene, especially for variable speeds of automobile conditions.

Reatomizing Device. A Re-Atomizing Device. Automotive Industries, vol. 44, no. 4, Jan. 27, 1921, p. 159, 1 fig. Spacer into which is pressed venturi throat carrying four small tubes is placed between carburetor and manifold. Ejector effect on four tubes which extend into throat tends to draw into annulus any liquid gasoline which may be passing up wall of carburetor and to eject it from tubes in atomized condition.

CARS

Container. Container Car in Express Service on N. Y. C. Lines. Ry. Age, vol. 70, no. 5, Feb. 4, 1921, pp. 315-316, 4 figs. Experimental car operated between New York and Chicago by Am. Ry. Express Co. Car is nine-section express car, its sectional cargo space consisting of nine separate containers or steel boxes firmly secured on car to prevent shifting during train movement.

CASE-HARDENING

Bibliography. Review of Case Carbonizing, 1920, O. A. Knight. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 51-54 and 65. Review and synopsis of important articles relative to case carbonizing which have appeared in current technical journals during past year.

Nitrogen and. Nitrogen and Case-Hardening, Henry Fay. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 289-290. Nitrogenizing process which takes place when steel is heated in cyanide.

Steel. A New Method of Case Hardening Steel, William J. Merten. Trans. Am. Soc. for Steel Treating, vol. 1, no. 4, Jan. 1921, pp. 270-273, 1 fig. Heated steel is brought into contact with pure nascent gas continuously generated in separate unit, preferably under pressure.

CAST IRON

Briquetting Refuse. The "Boreas" Cast-Iron Refuse Briquetting Machine. Foundry Trade Jl., vol. 23, no. 229, Jan. 6, 1921, p. 20, 1 fig. Manufactured by Colley Engineering & Machinery Co., London, England.

CEMENT

Bauxite. Cast Cements and the Electric Furnace, M. J. Bied. Practical Engr., vol. 63, no. 1767, Jan. 6, 1921, pp. 6-7, 2 figs. Strength of bauxite cement. Translated from Revue de l'Ingenieur et Index Technique.

CEMENT, PORTLAND

"Marque Speciale." "Marque Speciale" Swiss Cement. Cement & Eng. News, vol. 33, no. 2, Feb. 1921, pp. 30-32. Portland cement with properties for developing early strength.

CENTRAL STATIONS

Economical Developments. Policies for Future Power Development, John Price Jackson. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 102-106 and (discussion) pp. 106-107, and 110. Demand for central-station electric power in U. S. is contrasted with situation in England, and physical, public and financial relationships that are essential for relieving present stress and meeting that demand with reasonable economy and conservation of natural resources and labor are set forth.

France. Project of Departmental Distribution of Electrical Energy in Savoie (Projet de reseau départemental de distribution d'énergie électrique en Savoie). Revue générale de l'Electricité, vol. 9, no. 5, Jan. 29, 1921, pp. 147-150, 1 fig. Project for construction of central electric station in French department.

New York Metropolitan District. Heat, Light and Power for the Metropolitan District of New York.

William Barclay Parsons. Power, vol. 53, no. 8, Feb. 22, 1921, pp. 324–326. Economical advantages of constructing central station to supply needs of district. Total installation in district amounted in 1919 to 2,100,000 hp. and it is expected this will increase in 1930 to 4,500,000 hp.

Operation. Operation of Electric Central Stations (Etude des conditions de fonctionnement des centrales électriques), G. Jochmans. Société Belge des Electriciens, vol. 34, Nov.-Dec. 1920, pp. 261–273, 6 figs. Construction of load diagram. (To be continued.)

CHAINS

Testing. Chains and Lifting Gear. Mech. World, vol. 69, no. 1776, Jan. 14, 1921, pp. 36–37. Proving and testing. (Abstract.) Home Office pamphlet, of H. M. Stationery Office, Imperial House, London.

CHUCKS

Magnetic. Magnetic Chucks, Ellsworth Sheldon. Am. Mach., vol. 54, nos. 4 and 5, Jan. 27 and Feb. 3, 1921, pp. 121–124 and 7 figs., 177–180, 8 figs. Principle of operation and structural details of various types; classification of magnetic chucks.

Magnetic Chucks—II. Am. Mach., vol. 54, Nos. 6, 7 and 8, Feb. 10, 17 and 24, 1921, pp. 213–217, 8 figs., 265–269, 14 figs., and 324–329, 12 figs. Feb. 10: History of developments. First magnetic chuck patent issued 48 years ago. Early chucks and their construction. Progress from 1873 to 1914. Feb. 17: Characteristics of various types. Feb. 24: Downes, Patton and Walker types.

CLUTCHES

Ring. The Design of Expanding Ring Clutches, W. A. Milnes. Mech. World, vol. 69, no. 1776, Jan. 14, 1921, pp. 25–26, 4 figs. Computation of dimensions.

COAL

Briquetting. Anthracite Conservation by Briquetting, A. L. Stillman. Coal Industry, vol. 4, no. 2, Feb. 1921, pp. 100–103, 4 figs. Description of briquetting plant.

Distillation. By-Products of Coal Distillation (L'extraction des différents produits de la distillation de la houille), A. Grebel. Génie Civil, vol. 78, no. 2, Jan. 8, 1921, pp. 35–37, 2 figs. Processes and installation of Commentry-Fourchambault et Decazeville Society.

Recovery from Ashes. Fuel Recovery from Ashes. Eng. Production, vol. 2, no. 16, Jan. 20, 1921, p. 99, 1 fig. Typical plant in operation in French works for recovery from ashes unburnt coal in form of coke breeze.

COAL BREAKERS

Concentrating Tables. New Methods are Used for Preparing Small Sizes by Locust Mountain Coal Co., Dever C. Ashmead. Coal Age, vol. 19, no. 4, Jan. 27, 1921, pp. 171–179, 16 figs. At Weston Colliery Breaker sizes below pea are cleaned by concentrating tables and specially designed jig.

COAL HANDLING

Government Yard. How Uncle Sam Handles Coal at Washington, Frederick G. Cottrell. Coal Trade Jl., vol. 52, nos. 4 and 5, Jan. 26 and Feb. 2, 1921, pp. 113–115, 2 figs. and 142–144, 5 figs., Jan. 26: Layout of government yard which delivered 193,278 gross tons to various departments during past fiscal year. Feb. 2: Bin construction for loading of trucks.

Pipe Lines. Pumping Coal from Mine to Seaboard, C. H. Thomas. Sci. Am., vol. 124, no. 7, Feb. 12, 1921, pp. 121, 126 and 139, 7 figs. Scheme for shipping coal through pipe lines.

Scraper Loading. Costs of Scraper Loading and Conditions Under Which It Works Best, A. B. Benedict. Coal Age, vol. 19, no. 5, Feb. 3, 1921, pp. 222–226, 4 figs. Where coal is clean, faces fairly long, top good and above all where cars can be supplied regularly and in adequate number, scraper loader has successfully met widely varying conditions.

COAL MINES

Bituminous, Fire Prevention in. Causes and Prevention of Fires and Explosions in Bituminous Coal Mines, Edward Steidle. Dept. of Interior, Bur. of Mines, Miners' Circular 27, 1920, 75 pp. 117 figs. List of common causes of fires and explosions, prepared from examination of report of State Mine Dept. and of Bur. of Mines.

Electricity in. State Mining Laws on the Use of Electricity in and about Coal Mines, L. C. Ilsley. Dept. of Interior, Bur. of Mines, technical paper 271, 1920, 53 pp., 1 fig. 28 states have regulations prepared by commissions or enacted laws governing operation of coal mines.

COAL TAR

Research. Coal-Tar Research at Shadyside, John Morris Weiss and Charles Raymond Downs. Chem. & Metallurgical Eng., vol. 24, no. 4, Jan. 26, 1921, pp. 150–155, 6 figs. Account of expansion of scope and facilities of research department of Barrett Co. Study of physical properties, methods of testing and development of synthetic products.

COAL WASHING

Experimental Station. Coal Washing at the Northwest Experimental Station, Earl R. McMillan. Elec. Rev. (Chicago), vol. 78, no. 4, Jan. 22, 1921, pp. 142–145, 2 figs. Bur. of Mines plant prepared to recover 150,000 tons of culm in one dump

COKE

Hardness Testing. Importance of Hardness of Blast Furnace Coke, Owen R. Rice. Iron Age, vol. 107, no. 6, Feb. 10, 1921, pp. 380–381, 1 fig. Apparatus used at Bethlehem Steel Co. to determine hardness of coke. (Abstract.) Paper read before Am. Inst. Min. & Metallurgical Engrs.

COKE MANUFACTURE

Demster-Toogood Retorts. Demster-Toogood Continuous Verticals at Hawick. Gas World, vol. 74, no. 1905, Jan. 22, 1921, pp. 64–66, 2 figs. Demster-Toogood patented coking retort.

COKE-OVEN GAS

Composition. Composition of Coke-Oven Gases (Sur la composition de quelques gaz de fours à coke), P. Lebeau and A. Damienn. Comptes rendus des séances de l'académie des Sciences, vol. 171, no. 26, Dec. 27, 1920, pp. 1385–1386. Records of examinations.

COKE OVENS

By-Product. By-Product Coke Oven Plants of Yesterday and Today, J. M. Hastings, Jr. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 10–13, 6 figs. Progress of art in 28 years as illustrated by old and new plants of Semet-Solvay Co. Despite improvements original characteristics still remain.

Jones & Laughlin New By-Products Plant. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 13–17, 1 fig. Plant consists of five batteries of by-product ovens, each battery having 60 ovens of Koppers crossed regenerative type.

The By-Product Coke Oven Industry, 1920, C. J. Ramsburg. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, p. 18. First large battery of triangular-flue-type ovens completed and successfully operated during year. Special construction features of installations of year.

COMPRESSED AIR

Metering. The Metering of Compressed Air, John L. Hodgson. Colliery Guardian, vol. 121, no. 3135, Jan. 28, 1921, pp. 271–272, 10 figs. Types of meters in use. Paper read before Midland Inst. Min., Civil & Mech. Engrs.

CONCRETE

Porous. Secrets of Porete Manufacture, Ernest Walter. Tech. Eng. News, vol. 1, no. 10, Feb. 1921, pp. 5 and 12, 3 figs. Naphthalene or paraffin is mixed with cement in ordinary mixer and mixture poured into moulds of any desired shape. After setting for 24 hrs. slabs are removed and put into large tank to which steam is applied. Chemical melts slowly out of mixture.

Specifications. Some Controversal Points in Concrete Specifications, Frank Barber. Jl. Eng. Inst. of Canada, vol. 4, no. 2, Feb. 1921, pp. 117–122. Discussion on difficulties in preparing concrete specifications, with particular reference to provision of greater detail in clauses dealing with workmanship.

Strength. How Quantity of Mixing Water Affects Strength of Concrete. Eng. World, vol. 18, no. 2, Feb. 1921, pp. 95, 1 fig. Diagram constructed from tests made at Structural Material Research Laboratory, Lewis Inst., Chicago. Rule derived is to use smallest quantity of mixing water that will produce workable mix.

Tannic Acid, Effect on. Effect of Tannic Acid on the Strength of Concrete, Duff A. Abrams. Structural Matls. Research Laboratory, Lewis Inst., bul. 7, Nov. 1920, 31 pp., 16 figs. Tests conducted under auspices of Am. Soc. for Testing Matls. Strength of concrete was reduced for all percentages of tannic acid, for all mixes and ages used. Less than 0.1 per cent of tannic acid in terms of weight of aggregate may reduce strength of concrete to one-half its normal value. Reprinted from Proc. Am. Soc. for Testing Matls.

CONCRETE CONSTRUCTION

Costs. On the Economics of Building Design, J. Morrow Oxley. Jl. Eng. Inst. of Canada, vol. 4, no. 2, Feb. 1921, pp. 123–130, 8 figs. Graphs and tables showing relative effect on cost of variations in proportions, dimensions and floor loading for standard types of buildings.

Hessian System. The Hessian Fabric System of Concrete Construction. Concrete & Constructional Eng., vol. 16, no. 1, Jan. 1921, pp. 62–64, 3 figs. Walls are erected in situ by means of wooden molds which are raised course by course until wall is completed.

Stresses. Latest Developments in Concrete, H. C. Boyden. Nebraska Blue-Print, vol. 19, no. 4, May 1920, pp. 72–85. Survey of researches on stresses of concrete structures, and of laws which have been formulated for designing them.

CONCRETE, REINFORCED

Bond in. Bond in Reinforced Concrete. Engr. vol. 131, no. 3395, Jan. 21, 1921, pp. 65–66. Results of tests in which bars were pushed through prisms of concrete. Comparison with tests in which bars were pulled out.

Slabs. The Strength of Reinforced-Concrete Slabs with Cross-Reinforcement (Krydsarmerede Jærnbetonpladers Styrke), N. J. Nielsen. Ingeniören, vol. 29, no. 94, Nov. 24, 1920, pp. 723–728, 8 figs. It is shown that the ultimate stresses in reinforced-concrete can be calculated by means of differential equations. Numerical examples for square and rectangular plates.

Stress Formula. Formula for Computing Compressive Stress that can be Borne by Reinforced Concrete (Formule rationnelle du taux de compression du béton), M. Mougnié. Annales des Ponts et Chaussées, vol. 5, no. 10, Sept.-Oct. 1920, pp. 142–154. Formula involving coefficient which is ratio of theoretical moduli of elasticity of steel and concrete.

CONTRACTORS

Code of Ethics. Proposed Code of Ethics for Contractors. Eng. News-Rec., vol. 86, no. 6, Feb. 10, 1921, pp. 257–258. Submitted at New Orleans convention for consideration of the members of Associated General Contractors.

CORE OVENS

Electric. Electric Heating in the Iron Industry, Wirt S. Scott. Iron Age, vol. 107, no. 6, Feb. 10, 1921, pp. 384–385. Development of electric core ovens for foundry and experiences with heat treating furnaces.

COST ACCOUNTING

Power Plants. Armour System of Power Plant Accounting—II, O. A. Anderson. Power, vol. 53, no. 5, Feb. 1, 1921, pp. 170–174, 11 figs. Report system supplemented by charts and table to eliminate calculations.

CRANES

Control Apparatus. The Bergmann System of Control of Crane Hoisting Gear (Steuerung von Kranhubwerken, System Bergmann), Ernst Blau. Elektrotechnik n. Maschinenbau, vol. 39, no. 3, Jan. 16, 1921, pp. 29–31, 1 fig. Describes arrangement and operation of control apparatus developed by the Bergmann Electrical Works, Berlin, with which it is possible to effect a speed range from 1 to 60, and which has given satisfactory service in workshops, foundries, steelworks, etc.

Floating. Self-Propelled Floating Crane. Steamship, vol. 32, no. 379, Jan. 1921, pp. 177–178, 1 fig. 200-ton floating crane at Mersey Docks and Harbour Board, Liverpool.

CRANKSHAFTS

Crankpin Turning Machine. Rotating-Tool Crank Pin Turning Machine. Engr., vol. 131, no. 3396, Jan. 28, 1921, pp. 102–103, 3 figs. Machine belongs to class in which crankshaft is held stationary while tools for turning up pins and inside surfaces of webs are carried in revolving slide. Manufactured by George Richards & Co., England.

D

DIE CASTINGS

Uses. Application of Inserts to Die Castings, M. Stern. Am. Mach., vol. 54, no. 7, Feb. 17, 1921, pp. 284–286, 9 figs. Division of application of inserts into four general groups. Various methods of providing inserts with anchors. Locating points.

DIES

Manufacture. A School for Die Sinkers, J. H. G. Williams. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 36–38. Manner in which die-sinkers' school is conducted by Billings & Spencer Co., Hartford, Conn.

Composition and Hardening Die Blocks, James H. Herron and A. L. Wurster. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 34–36. Physical properties conferred by composition. Tempers at which die blocks are furnished.

The Design and Construction of Press Tools—I. Eng. Production, vol. 2, no. 18, Feb. 3, 1921, pp. 148–149, 4 figs. Table of allowances for punch and die for different thicknesses and materials.

DIESEL ENGINES

Armstrong-Sulzer. The Armstrong-Sulzer Marine Diesel Engine. Steamship, vol. 32, no. 379, Jan. 1921, pp. 179–182, 5 figs. Manufactured by Sir W. G. Armstrong, Whitworth & Co., England.

Marine. Marine Diesel Engine of 5,400 Shaft Horse-Power. Motorship, vol. 6, no. 2, Feb. 1921, p. 121, 2 figs. Sulzer two-cycle motor for propulsion of ocean liners.

Nordberg. Nordberg 2000 B. H. P. Two-Cycle Diesel Engine. Motorship, vol. 6, no. 2, Feb. 1921, pp. 114–118, 5 figs. Carels type four-cylinder engine with 500 b.hp. cylinder output.

Shop, Glasgow. Diesel-Engine Works in Glasgow (Dieselmaschinenfabrik in Glasgow), Karl Bernhard. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 4, Jan. 22, 1921, pp. 85–88, 12 figs. Notes on location, arrangement, design, foundation and heating of plant designed by author, work on which was begun under his superintendence in 1913, and greater part of iron construction and machinery was supplied by German firms.

Solid-Injection. New American Solid-Injection Engine. Motorship, vol. 6, no. 2, Feb. 1921, pp. 134–135, 5 figs. Small marine Diesel-motor with mechanical-injection of fuel, built on Pacific coast.

DRILLING

Square Holes. Square Hole Drilling Attachment. Engineering, vol. 111, no. 2872, Jan. 14, 1921, pp. 43–44 and 46, 9 figs. Radbore head for drilling square holes from solid exactly as ordinary drilling machine drills round holes only difference in operation being that feed is put on traversing work instead of traversing drill.

DRILLING MACHINES

Pneumatic Clamps. Pneumatically Operated Clamps for Drilling Machines, J. V. Hunter. Am. Mach., vol. 54, no. 5, Feb. 3, 1921, pp. 180–181, 4 figs. Devices developed in locomotive shops of Wabash Railroad Co., Decatur, Ill.

Vertical. A New Vertical Drilling Machine. Eng. Production, vol. 2, no. 16, Jan. 20, 1921, p. 103, 2 figs. Machine is designed for high-speed twist

drills and is capable of drilling holes up to 2 1/2 in. diameter in steel. It is manufactured by Fairbairns & Co., Leeds, England.

DROP FORGING

Industry. The Drop Forging Industry in 1920–1921, L. W. Alwyn Schmidt. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 4–7. Past year was one of general readjustment. Change in business psychology recommended. Effect of readjustment of prices on level of production still in excess of prewar volume.

DYNAMOMETERS

Heenan-Froude. The Heenan-Froude Dynamometer. Flight, vol. 13, no. 4, Jan. 27, 1921, pp. 65, 2 figs. Dynamometer for testing internal-combustion engines.

E

EFFICIENCY, INDUSTRIAL

Olympia Exhibition. The "Efficiency" Exhibition at Olympia. Engineering, vol. 111, no. 2876, Feb. 11, 1921, pp. 176. Machine and methods designed to bring about personal and civic efficiency and efficiency of transport of production and of use of fuel. (To be continued.)

ELECTRIC DRIVE

Industrial Applications. The Electric Drive in Industry. Beama, vol. 8, no. 1, Jan. 1921, pp. 45–54, 15 figs. Applications of electric drive to printing presses, and machine tools.

ELECTRIC FURNACES

Fuel-Fired Furnaces vs. Relative Thermal Economy of Electric and Fuel-Fired Furnaces, E. F. Collins. Trans. Am. Soc. for Steel Treating, vol. 1, no. 4, Jan. 1921, pp. 217–227 and (discussion) pp. 227–229, 5 figs. Graphs showing relative efficiency at various temperatures, also relative cost of fuel and fuel heat losses.

Induction. High-Frequency Induction Steel-Furnace, E. F. Northrup. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 309–311, 3 figs. Combination of crucible-melting flexibility with advanced practice of electric melting, manufactured by Ajax Electrothermic Corp.

Iron Foundries. Electric Furnaces in the Iron Foundry, Richard Moldenke. Iron Age, vol. 107, no. 7, Feb. 17, 1921, pp. 437–439. Costs and advantages of duplexing or electric melting of cold scrap. Control of sulphur, manganese and phosphorus. Paper before Am. Inst. Min. & Metallurgical Engrs.

Non-Ferrous Metals. Electric Furnaces for Non-Ferrous Metals. John B. C. Kershaw. Engr., vol. 131, no. 3394, Jan. 14, 1921, pp. 44 and 48–50, 7 figs. Results of tests made under three different systems of operation with two furnaces, one of ordinary brass-melting type, provided with lift-out crucible, and other of tilting type. Systems of operation were (1) continuous operation for 24 hours a day, (2) 10-hr. operation, and (3) special 10-hr. operation, in which sufficient power was maintained during night to keep furnace hot.

Oil, Gas and Coal Furnaces vs. Relative Economy of Oil, Gas, Coal and Electric Heated Furnaces, Seth A. Moulton and W. H. Lyman. Trans. Am. Soc. for Steel Treating, vol. 1, no. 4, Jan. 1921, pp. 249–270. Comparative operating costs, comparative annual production, and comparative advantages and disadvantages.

Operation. Operating Details of Electric Furnaces, Edward T. Moore. Chem. & Metallurgical Eng., vol. 24, no. 4, Jan. 26, 1921, pp. 171–176, 7 figs. Excerpt from report of electric furnace committee of Association of Iron & Steel Electrical Engineers based on questionnaire submitted to steel manufacturers operating electric furnaces.

Russ. A New Electric Arc Furnace (Ein neuer elektrischer Lichtbogenofen), E. Fr. Russ. Giesserei-Zeitung, vol. 18, no. 1, Jan. 1, 1921, pp. 3–5, 2 figs. Description of the Russ furnace, said to possess important advantages over former types; it can be used for melting copper, aluminum, other metals and alloys, as well as for the production of pig-iron casting, special steel, ferromanganese, ferrosilicon, etc.

Smelting. Electric Smelting Furnaces—I, F. Rowlinson. Beama, vol. 8, no. 1, Jan. 1921, pp. 14–22, 8 figs. Survey of developments in utilization of electric furnace for steel making.

Steel Manufacture. English and American Types of Electric Iron and Steel Furnaces Compared, John B. C. Kershaw. Foundry Trade Jl., vol. 23, nos. 229, 230 and 231, Jan. 6, 13 and 21, 1921, pp. 5–7, 2 figs., 29–30, 2 figs., and 53–55, 3 figs. Heroult, Ludlum and Renuerfelt types.

The Electric Furnace, E. T. Moore. Assn. Iron & Steel Elec. Engrs., vol. 3, no. 1, Jan. 1921, pp. 5–8. Recent applications, specially in steel manufacture.

[See also STEEL CASTINGS, Electric Melting.]

ELECTRIC LOCOMOTIVES

Comparison of Types. Economic and Constructive Aspects in the Construction of Modern Large Electric Locomotives (Wirtschaftliche u. konstruktive Gesichtspunkte im Bau neuerer Gross-Elektrolokomotiven), Alb. Laternser. Schweizerische Bauzeitung, vol. 77, no. 5, Jan. 29, 1921, pp. 49–51, 6 figs. Description of the 1C + C1 type of the Swiss Federal Railway for high-voltage single-phase current, 15,000 volt, 16 1/3 periods, and the 2 C 2 type Gr. E 332 of the Italian State Railroad for 3-phase current 3000 volt, 16 1/3 periods, both constructed by the Oerlikon Machine Factory; and a comparison of them with recent American types of the Gen. Elec. and Westinghouse Cos.

Design. The Application of the Electric Locomotive to Main-Line Traction on Railways, H. E. O'Brien. Jl. Instn. Elec. Engrs., vol. 28, no. 295, Sept. 1920, pp. 858–869, 9 figs. Elements of design are developed from examination of performance data of C. M. & St. P. Railway and on Italian and Swiss railways.

Freight. Freight Electric Locomotives of the Swiss Federal Railways, Constructed by Oerlikon Works (Locomotives électriques à marchandises des chemins de fer fédéraux suisses construites par les ateliers d'Oerlikon). Génie Civil, vol. 78, no. 2003, Jan. 1, 1921, pp. 1–3, 2 figs. Type, 2–6–6–2; tension, 15,000 volts; maximum grade, 26 per cent; horsepower, 1700.

Operation. Train Handling with Electric Locomotives, W. S. H. Hamilton. Ry. Age, vol. 70, no. 3, Jan. 21, 1921, pp. 227–231, 5 figs. Records of operation in electrified section of C. M. & St. P. Railway.

ELECTRIC WELDING

Seam-Welding, Machines. Electric Seam-Welding Machines, Alfred Gradenwitz. Am. Mach., vol. 54, no. 4, Jan. 27, 1921, pp. 128–129, 5 figs. Intermittent process designed by German firm.

Steel-Frame Buildings. Electrically Welded Steel Frame Building. Engineering, vol. 111, no. 2872, Jan. 14, 1921, pp. 55–56, 8 figs. Details of buildings constructed by welding methods in England.

EMPLOYMENT MANAGEMENT

Des Moines Employment Association. Consolidate Employment Study, H. C. Pfund. Iron Trade Rev., vol. 68, no. 4, Jan. 27, 1921, pp. 286–289 and 293, 6 figs. Association formed by employers in Des Moines, Iowa, "to promote harmony and coöperation between employer and employee," and to "encourage continuous employment."

Duties of Manager. The Employment Manager in an Engineering Works. Engineering, vol. 111, no. 2873, Jan. 21, 1921, pp. 65–66. Duties of manager. Technique of hiring men.

Railways. The Functions of a Railway Employment Service. J. C. Clark. Ry. Age, vol. 70, no. 5, Feb. 4, 1921, pp. 329–331. Methods of selecting best men and following up new employees.

Selecting Employees. Simple Tests for Selecting Office Workers, Eugene J. Benge. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 91–93, 3 figs. Suggests method of devising and standardizing clerical tests.

Sizing Up the Qualities of a Man. Walter D. Scott. Can. Manufacturer, vol. 41, no. 2, Feb. 1921, pp. 39–41, 1 fig. Suggested classification of personnel qualifications. Position for which man of known character is best suited.

The Present Status of Industrial Psychotechnology with Special Regard to Foundry Practice (Der gegenwärtige Stand der industriellen Psychotechnik unter besonderer Berücksichtigung des Giessereigewerbes), W. Moede. Giesserei-Zeitung, vol. 18, nos. 1 and 2, Jan. 1 and 15, 1921, pp. 1–3 and 24–27, 8 figs. Brief outline of the present approved methods for the psychotechnical testing of the adaptability of industrial apprentices and discussion of their practical value.

ENAMELS

Iron and Steel. A Reading List on Vitreous Enameling on Iron and Steel, Clarence Jay West. Jl. Am. Ceramic Soc., vol. 4, no. 1, Jan. 1921, pp. 47–64. Bibliography for years 1907 to 1920.

ENGINEERS

Training of. Some Suggestions for the Training of Engineers, Aunson S. J. Hall. Trans. Inst. Mar. Engrs., vol. 32, Dec. 1920, pp. 251–267 and (discussion) pp. 267–277. Combination of technical training and industrial apprenticeship.

EXECUTIVES

Duties of. How to Develop Executive Ability Through Personality, G. Sumner Small. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 115–118. Study of principle underlying good organization. Means whereby executive can definitely, systematically and surely build morale in his subordinates.

EXHAUST STEAM

Utilization of. Utilization of the Exhaust Heat of a 100-Hp. Reciprocating Steam Engine (Die Abwärmeausnutzung einer 100-PSi-Kolbendampfmaschine). Elektrotechnischer Anzeiger, vol. 38, no. 11, Jan. 20, 1921, pp. 49–50. Shows with the aid of an example to what extent the exhaust steam of an engine using superheated steam can be utilized.

F

FACTORIES

Construction. Features of the New Dunlop Factory, Bernard H. Prack. Can. Manufacturer, vol. 41, no. 2, Feb. 1921, pp. 35–38, 5 figs. Construction details, layout and equipment of factory and office building.

Machine Tool Plant of New Design, F. L. Prentiss. Iron Age, vol. 107, no. 5, Feb. 3, 1921, pp. 311–316, 11 figs. Modified monitor roof instead of sawtooth type in plant of Foote-Burt Co., Cleveland.

The "Fordson" Factory—Cork, H. C. Johnson. Concrete & Constructional Eng., vol. 16, no. 1, Jan. 1921, pp. 5–13, 10 figs. Layout and structural details of concrete buildings.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FARM MACHINERY

Electric vs. Steam Drive. Electric Motor vs. Locomobile (Elektromotor oder Lokomobile?), B. Jacobi. Elektrotechnischer Anzeiger, vol. 38, nos. 6, 7 and 8, Jan. 12, 13 and 15, 1921, pp. 25–26, 29–30 and 33–34. Discussion of the relative economy of steam- and electrically-driven farm machinery.

FATIGUE

Industrial. Fatigue in Steel Works. Iron & Coal Trades Rev., vol. 102, no. 2758, Jan. 7, 1921, pp. 6–9. Report of Industrial Fatigue Research Board, England.

Industrial Fatigue, Charles S. Myers. Jl. Royal Soc. of Arts, vol. 69, no. 3558, Jan. 28, 1921, pp. 150–156 and (discussion) pp. 156–159. Method of measuring fatigue.

Output in Boot and Shoe Factories. Eng. & Indus. Management, vol. 5, no. 3, Jan. 20, 1921, pp. 70–72, 9 figs. Investigations carried out by Industrial Fatigue Research Board.

FERROMANGANESE

Electric-Furnace Production. The Electric Furnace for Production of Ferromanganese, E. S. Bardwell. Jl. Electricity & Western Industry, vol. 46, no. 3, Feb. 1, 1921, pp. 120–122. Method of Anaconda Copper Mining Co.

FIRE EXTINGUISHERS

Carbon Tetrachloride. Corrosive Action and Products Formed when Carbon Tetrachloride Extinguisher Liquids are Applied to Fires, A. H. Nuckolls. Nat. Fire Protection Assn., vol. 14, no. 3, Jan. 1921, pp. 221–236, 5 figs. Tests to determine corrosive action and nature of fumes resulting from application of carbon tetrachloride extinguisher liquid to fires.

FIREBRICK

Spalling. A Study of Spalling, Raymond M. Howe and Robert F. Ferguson. Jl. Am. Ceramic Soc., vol. 4, no. 1, Jan. 1921, pp. 32–46, 11 figs. Comparison of laboratory spalling tests of firebricks and behavior in service.

FOREMEN

Duties of. The New Foreman for the New Day—Fred H. Rindge, Jr. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 109–111. Duties and responsibilities of foremen.

FORGING

Drop Hammers. Application of Compressed Air to Drop Hammers and Forging Presses. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, p. 27. Details of work done at U. S. Navy Yard, Norfolk, Va.

Forge Shops. Forge Plant for 75 MM Projectiles, T. W. Towler. Blast Furnace & Steel Plant, vol. 9, no. 2, Feb. 1921, pp. 168–171, 5 figs. Shop designed to turn out from 50,000 to 55,000 shell forgings daily.

Gun-Forging Plant. Armor-Plate and Gun-Forging Plant of the United States Navy. Roger M. Freeman. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 14–26, 10 figs. Description of government-built and operated naval ordnance plant at South Charleston, West Va. "H" type forge and furnace building among features of plant.

Swaging. Swaging Practice—II (Plaudereien aus der Gesenkschmiede), Paul Heinrich Schweissguth, Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 5, Jan. 29, 1921, pp. 109–115, 37 figs. Deals with molding of swages. Working process is exemplified on a shrapnel double fuse. Notes on raw material, swage, swage with several parts, preliminary swaging, losses of material through waste and removing fins; determination of the preliminary swage; errors in design of swages and their prevention; useful possibilities of process.

FORGINGS

Sand-Blasting. Sand-Blasting Forgings and Sand, Blasting Versus Pickling, H. D. Gates. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 72–74, 4 figs. Comparison of costs.

FOUNDRIES

Germany. Shows Trends in German Practice, Hubert Hermanns. Foundry, vol. 49, no. 3, Feb. 1, 1921, pp. 92–93, 3 figs. Developments in molding and metallurgical practice as featured at annual meeting of German Iron Foundries Assn.

Natural-Gas Melting. Melts Gray Iron with Natural Gas. Foundry, vol. 49, no. 4, Feb. 15, 1921, pp. 139–142, 5 figs. Experience of company in melting gray iron with natural gas without regenerating either gas or air.

Steel. Combines Steel and Alloys Casting, Hubert Hermanns. Foundry, vol. 49, no. 4, Feb. 15, 1921, pp. 154–157, 6 figs. Mark Steel foundry of Wengern, Germany.

Dust Removal in. Arrangement and design of Dust-Removal Plants for Foundry Cleaning shops (Anordnung und Bemessung von Entstaubungsanlagen für Gussputzereien), W. Kaempfer. Stahl u. Eisen, vol. 41, no. 4, Jan. 27, 1921, pp. 110–113, 8 figs. Gives average values showing volumes of air to be exhausted per minute for various classes of machines, and describes different methods for the separation of dust and the different types of machines used therefor.

[See also MOLDS.]

FUELS

Oil. See OIL FUEL.

Solid, Patented. Progress in Furnace Installations for Solid Fuels (Neuerungen an Feuerungsanlagen für feste Brennstoffe), H. Pradel. Feuerungstechnik, vol. 9, no. 8, Jan. 15, 1921, pp. 65–69, 10 figs. Quarterly yearly report. Review of recent domestic and foreign patents.

Turf. A New Process of Drying Turf for Fuel in Finland. Chem. & Metallurgical Eng., vol. 24, no. 5, Feb. 2, 1921, p. 215. Raw turf in swamp is freed from all old roots and changed to thin mud, by powerful jet of water under pressure of 20 atmospheres. Mud is pumped out on drying field and spread in layers from 20 to 30 cm. in depth which are subsequently cut into bricks.

Utilization. The Work of the Committee for the Utilization of Fuels (Travaux de la commission d'utilisation des combustibles), Cornu-Thénard. Revue de Métallurgie, vol. 17, no. 11, Nov. 1920, pp. 757–764. Committee was appointed by French Ministry of Public Works. First report of Committee deals with results obtained in steel works with mixture of coal and wood in Martin furnace.

[See also COAL; LIGNITE, OIL FUEL; PULVERIZED COAL.]

FURNACES

Recuperative. A New Type of Recuperative Furnace. Foundry Trade Jl., vol. 23, no. 230, Jan. 13, 1921, pp. 32–34, 5 figs. Developed in connection with research work on glass and refractories carried on at National Physical Laboratory, England.

FURNACES, ANNEALING

Continuous. Tunnel Furnace for Continuous Annealing. Iron & Coal Trades Rev., vol. 102, no. 2759, Jan. 14, 1921, p. 49, 2 figs. Advantages claimed for tunnel type of furnace is that by gradual advance of cold material into annealing zone all calorific value of waste gases can be usefully absorbed, leaving only sufficient temperature in outlet to create necessary draft in chimney stack.

FURNACES, BOILER

Lignite-Burning. The Adaptation of Steam-Boiler Furnaces to Lignite Coals (Die Umstellung der Dampfkesselfeuerungen auf Rohbraunkohle), H. Pradel. Braunkohle, vol. 19, nos. 38, 39 and 40, Jan. 1, 8 and 15, 1921, pp. 469–472, 477–482 and 489–492, 7 figs. Impressions from the Furnace Engrs.' Convention in Berlin, Germany. Concludes with summary of author's recommendations.

Turbine. The Turbine Patent Furnace. Elec. Times, vol. 59, no. 1525, Jan. 6, 1921, p. 11, 2 figs. Designed on principle of impulse turbine. Air-trough corresponds to nozzle and fire-bars to blades of turbine.

FURNACES, ELECTRIC

See ELECTRIC FURNACES.

FURNACES, HEAT-TREATING

Electric. Recent Developments in Electric Heat-Treating Furnaces, H. O. Swoboda. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 83–85. Applications to date. Classification of electric heating furnaces as to resistor construction, resistor material, charging and operating and control. Discussion of cost of operation.

FURNACES, REVERBERATORY

Charging Method. New Method of Charging Reverberatory Furnaces, J. O. Ambler. Eng. & Min. Jl., vol. 111, no. 5, Jan. 29, 1921, p. 226, 1 fig. Experimental machine designed for charging material at practically continuous rate into furnace by mechanical means, without production of dust.

G

GAGES

Developments. Recent Developments in Gauging Apparatus. Eng. Production, vol. 2, no. 15, Jan. 13, 1921, pp. 40–44, 12 figs. Machines recently introduced by Alfred Herbert, Coventry, England, notably gear pitch and concentricity measuring machine and universal gage measuring machine.

Dial. Gauging with Dial Instruments. Engr., vol. 131, no. 3395, Jan. 21, 1921, pp. 76–77, 4 figs. Dial gages for gaging thickness, length, diameters, depth, etc.

GAGING

Limit. Limit Gauging. Jl. Instn. Mech. Engrs., No. 9, Jan. 1921, pp. 1089–1124, 25 figs. partly on 5 supp. plates. Technical considerations on formation of system of limits. Description of gage testing apparatus designed and used at National Physical Laboratory, England.

GAS ENGINES

Steel Works. The Gas Engine in Iron and Steel Works, T. B. Morley. Elecn., vol. 86, no. 2227, Jan. 21, 1921, pp. 99–102, 9 figs. Galloway tandem-cylinder engines.

Testing. The Working and Testing of a Gas Engine, Arthur G. Robson. Practical Engr., vol. 63, no. 1768, Jan. 13, 1921, pp. 20–23, 18 figs. Methods of testing.

GAS TURBINES

Elements. The Gas Turbine. B. Pochobradsky. Beama, vol. 8, no. 1, Jan. 1921, pp. 9–13. Gas turbines are classified into explosion and constant-pressure turbines. Technical elements of each of these types are studied.

French Patent. European Inventions, J. H. Blakey. Power Plant Eng., vol. 25, no. 4, Feb. 15, 1921, pp. 232–234, 4 figs. French patent for internal-combustion turbo-motor. Also patented alloy for internal combustion engine valves. Composition of alloy is nickel, 67 per cent; iron, 1 to 5 per cent; and copper, 28 to 32 per cent.

GAS WORKS

Developments. Gasworks Engineering in 1920. Engr., vol. 131, no. 3393, Jan. 7, 1921, p. 12. Survey of developments.

GASOLINE

Natural Gas. Gasoline by the Charcoal Absorption Process, G. A. Burrell, G. G. Oberfell and C. L. Voress. Chem. & Metallurgical Eng., vol. 24, no. 4, Jan. 26, 1921, pp. 156–160, 7 figs. Description of activated charcoal process for absorbing vapors from natural gas. Comparison with commercial processes; activated coconut shell charcoal; absorption and selection; steam distillation of saturated carbon; yields and quality of products.

Gasoline from Natural Gas. V—Hydrometer for Small Amounts of Gasoline, R. P. Anderson and C. E. Hinckley. Jl. Indus. & Eng. Chem., vol. 13, no. 2, Feb. 1921, pp. 144–145, 3 figs. Apparatus for rapid and fairly accurate determination of gravity of gasoline when quantity is insufficient to float usual type of hydrometer.

Peat as Source of. See PEAT, Gasoline from.

GEAR CUTTING

Hobbing Machines. Automatic Hobbing Machine. Iron Age, vol. 107, no. 4, Jan. 27, 1921, pp. 259–260, 3 figs. Machine designed for rapid production of helical and herringbone gears.

Newark No. 5 Automatic Gear-Hobbing Machine. Am. Mach., vol. 54, no. 4, Jan. 27, 1921, pp. 157–158, 1 fig. Machine designed for rapid production of helical gears.

GEARS

Grinding. The Precision Grinding of Hardened Gears. Eng. Production, vol. 2, no. 18, Feb. 3, 1921, pp. 158–161, 8 figs. Machine for grinding gears developed by Sulzer Bros., England.

Helical. See GEAR CUTTING, Hobbing Machines.

Worm. Worm Gear Design, S. Bramley-Moore. Machy. (Lond.), vol. 17, no. 434, Jan. 20, 1921, pp. 474–480, 20 figs. Study of forces acting, formulas for computing dimensions, and comparison of types of worm gears. Paper read before Instn. Automobile Engrs.

GRINDING

Centreless. Centreless Grinding. Eng. & Indus. Management, vol. 5, no. 2, Jan. 13, 1921, pp. 39–41, 3 figs. Machines which have been developed for grinding straight cylindrical work without centres.

Cylindrical, Speeds for. Work Speeds in Cylindrical Grinding. Machy. (Lond.), vol. 17, no. 434, Jan. 20, 1921, pp. 481–483. Importance of using proper speed. Fallacy of idea that the faster the rotation of work, the higher rate of production.

GRINDING MACHINES

Surface. Rotary Surface Grinding Machine. Engineering, vol. 111, no. 2874, Jan. 28, 1921, pp. 100–102, 13 figs. Constructed by Heald Machine Co., Worcester, Mass. Machine is designed for flat grinding of small articles such as can be held by magnetic chuck.

GUN METAL

Tests on. Gun-Metal, J. Arnott. Foundry Trade Jl., vol. 23, no. 229, Jan. 6, 1921, pp. 2–4, 11 figs. Suggests restriction of term "gun-metal" to ternary alloy copper-tin-zinc. Tests on metal of composition 87 per cent copper, 9 per cent tin, 3 per cent zinc and one per cent lead. Paper read before Scottish Branch Instn., British Foundrymen.

H

HACK-SAWING MACHINES

English. A New Hack Sawing Machine. Machy. (Lond.), vol. 17, no. 435, Jan. 27, 1921, p. 524, 2 figs. Designed to cut bars up to 6 in. diameter. Manufactured by Blundstone Engineering Service, Coventry, England.

HANDLING MATERIALS

Electric Power in. Application of Electrical Power to Modern Handling Plants, H. C. Widlake. Chem. Age (Lond.), vol. 4, no. 82, Jan. 8, 1921, pp. 38–40, 5 figs. Survey of developments.

Economies in Handling Materials in Industrial Plants, J. S. Tuthill. Elec. World, vol. 77, no. 4, Jan. 22, 1921, pp. 201–202. Instances of savings effected by electrically operated material handling machinery and examples of adaptation to cover varying needs.

Factories, Germany. Handling Materials in Factories (Werkstättentransporte), W. Dahlheim. Betrieb, vol. 3, no. 7, Jan. 10, 1921, pp. 187–192, 13 figs. Portable hoisting apparatus. It is claimed that the latest German types of portable elevators are far superior to those of American make. Details of a new patented one-man tipping and elevating truck lifting heavy loads from floors and raising them to proper height for loading on and in railroad cars.

Inter-Floor Transportation. Inter-Floor Transportation by the d'Humy Motoramp System, Harold F. Blanchard. Eng. World, vol. 18, no. 2, Feb. 1921, pp. 105–106, 2 figs. Staggered floor construction.

HEAT TRANSMISSION

Pipe Coverings. Emissivity of Heat from Various Surfaces, V. S. Day. Power House, vol. 14, no. 2, Jan. 20, 1921, pp. 17–23, 11 figs. Tests carried out at experiment station of University of Illinois. Heat loss was greater through asbestos paper-covered pipes than through same pipes uncovered.

HEATING

Catalytic Method. Heating by Catalysis (Le chauffage par catalyse), R. Villers. Nature (Paris), no. 2438, Dec. 25, 1920, pp. 415–416. Apparatus decomposes petroleum by catalysis in steam and carbonic acid by platinum in presence of air.

Systems, Cooling with. Method of Utilizing Heating Systems for Cooling Rooms in Summer, A. M. Feldman. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 1, Jan. 1921, pp. 15–18, 5 figs. Patented heating and cooling apparatus comprising pipe circuit, water radiators connected at top and bottom beater and cooler and valves for cutting heater and cutting out cooler, or vice-versa, flow through system when heater is cut in being in one direction through pipe circuit for heating and in opposite direction for cooling.

HEATING, ELECTRIC

Industrial. Unusual Industrial Heating Developments, Wirt S. Scott. Elec. World, vol. 77, no. 6, Feb. 5, 1921, pp. 307–310, 6 figs. Developments of electric air heating for textile mills. Typical uses to which electric heat can be applied.

HOISTS

Mine. Hoist Designed Specially for Use in Room Work. Coal Age, vol. 19, no. 5, Feb. 3, 1921, pp. 229–230, 2 figs. Six-jaw clutch holds or frees drum from shaft. Oil supply will last three months. Special provision for jack props.

Quincy Hoist—Largest in World, Thomas Wilson. Power, vol. 53, no. 3, Jan. 18, 1921, pp. 90–95, 12 figs. Compound condensing hoist with two high-pressure and two low-pressure cylinders, 38 and 60 x 66 in., with ultimate winding capacity of 13,300 ft. of $1^5/_8$ in. rope in single layer. Hoist operates in balance, raising 20,000 lb. rock per trip at rope speed of 3200 ft. per minute.

HOUSES, CONCRETE

England. Concrete Cottage Building. Housing at Liverpool. Concrete & Constructional Eng., vol. 16, no. 1, Jan. 1921, pp. 22–29, 9 figs. Heavy concrete walling patented by Economic Building Corporation.

HYDRAULIC JACKS

Stella. Hydraulic Jacks (Hydraulische Hebeböcke), H. Berthold. Der praktische Maschinen-Konstrukteur, vol. 54, no. 2, Jan. 13, 1921, pp. 12–15, 9 figs. Describes the Stella lifting jack constructed by the Klingelhöfer-Defries Works, Ltd., Düsseldorf, Germany, consisting chiefly of a water tank equipped with a horizontal pump and a cylinder and plunger. Its advantages are pointed out.

HYDRAULIC TURBINES

Design. Tendencies in Development of Hydraulic Prime Movers, S. L. Shuffleton. Jl. Electricity & Western Industry, vol. 46, no. 3, Feb. 1, 1921, pp. 116–118, 3 figs. Capability of handling increasingly higher heads and involving increasingly large concentration of power in single units.

Installations. New Western Turbine Installations, Lewis F. Moody. Jl. Electricity & Western Industry, vol. 46, no. 3, Feb. 1, 1921, pp. 119–120, 1 fig. Survey of turbine installations now under construction by I. P. Morris Dept. of William Cramp & Sons Ship & Engine Building Co., Philadelphia.

Lubrication. Lubrication of Hydraulic Turbines. Lubrication, vol. 6, no. 11, Dec. 1920, pp. 1–8, 9 figs. Scheme for lubrication of large turbines of Niagara Falls Power Co.

Niagara Falls Power Development. The Hydraulic Turbines for Niagara Falls. Power House, vol. 14, no. 2, Jan. 20, 1921, pp. 24–26, 6 figs. Each of these machines will develop 61,000 b.hp. at $187^1/_2$ r.p.m. They will be coupled to 45,000-kva. vertical generators. Turbine casing weighs 110 tons.

Theory. Contribution to the Theory of High-Speed Hydraulic Turbines (Contributo alla teoria delle turbine idrauliche veloci), Giacomo Büchi. Industria, vol. 34, no. 23, Dec. 15, 1920, pp. 561–567, 17 figs. Comparative examination of design features of leading types, together with records of experiments. (To be continued.)

Wellman-Seaver-Morgan. Hydraulic Turbines for Queenston Development. Can. Engr., vol. 40, no. 5, Feb. 3, 1921, pp. 185–186A, 6 figs. Casings, runners and speed rings of two Wellman-Seaver-Morgan units of 61,000 hp. capacity each.

HYDROELECTRIC PLANTS

France. Making Best Use of French Hydro Plant, Lucien Pahin. Elec. World, vol. 77, no. 7, Feb. 12, 1921, pp. 357–359. Originally designed for railroad electrification, station was utilized for war loads to alleviate loss of coal mines. How station, line and substations were changed to get maximum utilization of water.

The Great Modern Hydroelectric Plants (Les grandes distributions électriques modernes), A. Troller. Nature (Paris), no. 2433, Nov. 20, 1920, pp. 326–332, 7 figs. Tendencies in design and construction as shown in latest installations, notably hydroelectric plant at Eget in the Pyrénées.

Simplon Tunnel. The Termination of the Simplon Tunnel (L'achévement du tunnel du Simplon), J. Boudet. Vie technique & industrielle, vol. 2, no. 16, Jan. 1921, pp. 305–314, 30 figs. Hydroelectric installation at north entrance. (Continuation of serial.)

Surge Tanks. Diaphragm Increases Surge Tank Capacity. Can. Engr., vol. 40, no. 3, Jan. 20

1921, p. 145, 2 figs. Added penstock threatened to overtop tank, but surge is throttled down by plate with small opening.

Water Control. Water Control on Hydro-Electric Systems, R. C. Denny. Power, vol. 53, no. 6, Feb. 8, 1921, pp. 208–212, 10 figs. Operating procedure for hydroelectric system of six plants utilizing combined static head of 2637 ft. Description of storage reservoirs and methods of conveying water to plants. Measurement of evaporation from reservoirs. Evaporation from one reservoir has been as high as 30 acre-feet per day.

Water Supply, Forecasting. Snow Surveying for the Forecasting of Stream Flow, J. E. Church, Jr. Eng. News-Rec., vol. 86, no. 6, Feb. 10, 1921, pp. 244–248, 2 figs. Methods, factors and results in making spring predictions of summer water supply for irrigation and power in streams fed by mountain snows.

I

IMPACT

Duration of. Researches on Duration of Impact (Recherches sur la durée du choc), Georges Moreau. Annales de Physique, vol. 14, Nov.-Dec. 1920, pp. 306–333, 2 figs. Measurements of duration of impact between ball and plain by electrical process, and empirical formula for calculating it.

INDUSTRIAL MANAGEMENT

Budget-Control System. A Budget Control System which is Producing Results, Norman G. Shidle. Automotive Industries, vol. 44, no. 6, Feb. 10, 1921, pp. 269–271, 8 figs. System of management which enables distributors and managers to know which departments are making money and which are not making money. System developed at Packard-Chicago distributors.

Expense Reduction. How to Reduce Expenses without Hurting the Business. Factory, vol. 26, no. 2, Jan. 15, 1921, pp. 167–170 and 198, 2 figs. Suggestions from executives in representative industrial works.

Inspection. The Part Inspection Plays in Good Management, Howell B. May. Factory, vol. 26, nos. 2 and 3, Jan. 15 and Feb. 1, 1921, pp. 175–179, 5 figs., and 335–339, 4 figs. Organization and operation of inspection department and selection of necessary personnel.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 6, Dec. 25, 1920, pp. 44–45. Proposal of the Committee for Economic Production for instruction sheet for the use of tapers.

Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 7, Jan. 10, 1921, pp. 50–51. Proposal of the Committee for Economic Production for an instruction sheet for the fabrication and use of screw dies.

Nomenclature Systems. Systematic Nomenclature and Factory Organization (Bezeichnungs-systematik und Betriebsorganisation), Eduard Michel. Betrieb, vol. 3, no. 7, Jan. 10, 1921, pp. 165–177, 6 figs. It is shown that a symbol system composed of letters and numerals is superior to one consisting only of numerals, due to mnemonic simplifications. Writer advocates a comprehensive system of nomenclature and shows how, with the aid of a symbol system, concentration of energy and a considerable saving in mental and clerical work can be effected.

Organization. Organization is Death, James B. M. Clark, Jr. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 141–145. Arguments against and for specialization of work.

Overhead Expense. Distributing Overhead Expense by the Machine Hour Rate Method, Christopher Haigh. Automotive Industries, vol. 44, no. 4, Jan. 27, 1921, pp. 172–177. Advantages of machine hour rate method over four other methods —man rate, man hour, sold hour, and material and labor. Paper read before Am. Gear Manufacturers' Assn.

Planning. The possibilities of Planning, E. A. Pells. Eng. & Indus. Management, vol. 5, no. 3, Jan. 20, 1921, p. 69. Functions of planning office and its place in management administration.

Production Systems. An "I am Producing More" Contest that Doubled Output, C. W. Ferguson. Factory, vol. 26, no. 3, Feb. 1, 1921, pp. 332–334, 4 figs. Experience of company of plan which gave each worker that phrase as slogan.

Economics of Workshop Practice—Mass Production (Die Wirtschaftlichkeit der Werkstattarbeit. Massenfertigung), K. Jung, Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 4, Jan. 22, 1921, pp. 93–95. Author claims that present highly developed economic and industrial life calls for educated practitioners without whom no progress can be made, and points out that engineering students should be taught the value and necessity of practical work and practical education.

Economy in Single-Unit Manufacture (Wirtschaftlichkeit bei Einzelfertigung), J. Hanner. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 2, Jan. 8, 1921, pp. 29–35, 12 figs. Contrasts between mass and single-unit production; relationship between construction and production; assignment and distribution of work; measures for improvement in economical operation; superintendence; working plan and machine layout; conveyance equipment, etc.

Less Wages, or More Work? Maxwell Droke. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 103–105. Writer holds that 20 per cent increase in production is safer and saner than 20 per cent decrease in wages.

Modern Production Methods—XIV, W. R. Basset. Am. Mach., vol. 54, no. 5, Feb. 3, 1921, pp. 187–191, 8 figs. Method of analyzing labor costs and their relation to final cost of manufactured article.

Why Increase Production? J. H. H. Boyd. Eng. & Indus. Management, vol. 5, no. 3, Jan. 20, 1921, pp. 73–76. Writer questions whether call for increased production is justified under present-day conditions, and further analyzes aims and objects of Higher Production Council and deals with their method of applying principle of payment by results.

Routing. Handling and Routing Large Work. Machy. (Lond.), vol. 17, no. 435, Jan. 27, 1921, pp. 501–507, 17 figs. Methods for routing of work through factory.

Routing Considered as a Function of Up-to-Date Management—IV, H. K. Hathaway. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 126–134, 8 figs. Evolution of progress sheet into assembling route sheet.

Safety Departments. What is the Business of a Safety Department? Henry Landesman. Am. Mach., vol. 54, no. 7, Feb. 17, 1921, pp. 260–264. Significance of safety department in industrial plants. Advantages of safety departments.

Statistics, Compiling of. Making Statistics Talk —III, M. C. Rorty. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 119–125, 9 figs. Mathematical and semi-mathematical uses of graphics.

Stock Records. Accurate Methods in Keeping Stock Records, Fred J. Huntley. Automotive Industries, vol. 44, no. 3, Jan. 20, 1921, pp. 125–128, 6 figs. System at plant of Cadillac Motor Car Co., Detroit.

Tool Repairing. "Repairing Tools—One Hour." Factory, vol. 26, no. 2, Jan. 15, 1921, pp. 172–174, 5 figs. Time records for checking idle machines and men.

[See also EFFICIENCY, INDUSTRIAL.]

INDUSTRIAL RELATIONS

Arbitrating Disputes. When You Arbitrate, Chesla C. Sherlock. Am. Mach., vol. 54, no. 4, Jan. 27, 1921, pp. 130–132. Three kinds of arbitration recognized by law.

Collective Bargaining. Tyrannous Labor Leaders, Parlor Socialists and So-Called Collective Bargaining, Henry Herbert Squire. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 138–140. Protest against "tyranny of labor leaders."

Incentive Plans. How Rewards Help Workers at Their Jobs. Iron Age, vol. 107, no. 5, Feb. 3, 1921, pp. 317–320. Report of Committee on Labor Relations of Cleveland Chamber of Commerce.

Open Shop. Open Shop Wins at Golden Gate, Don Partridge. Iron Trade Rev., vol. 68, no. 6, Feb. 10, 1921, pp. 418–422, 5 figs. Works council system reported to be working satisfactorily in shipyards, commercial shops and manufacturing plants of San Francisco Bay District.

The Philosophy of the Closed Shop in Action, James A. Emery. Open Shop Rev., vol. 18, no. 1, Jan. 1921, pp. 3–24. Arguments in favor of adopting open-shop principle in U. S. Address delivered before Nat. Founders Assn.

Strikes. See STRIKES.

INDUSTRIAL TRUCKS

Railways. Electric Vehicles for Railway Purposes—II. Ry. Gaz., vol. 34, no. 3, Jan. 21, 1921, pp. 67–69, 6 figs. Device adopted by British railway companies.

INSULATORS, HEAT

Magnesia. Characteristics of 85 per cent Magnesia as a Non-Heat-Conducting Covering, Edward R. Weidlein. Heat. & Vent. Mag., vol. 18, no. 2, Feb. 1921, pp. 30–34, 11 figs. Results of tests, with curves showing most economical thickness of pipe covering for different conditions.

Conservation of Heat in Power and Heating Systems, Edward R. Weidlein. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 295–300, 10 figs. Discussion of 85 per cent magnesia insulation, showing low depreciation rate under wetting and drying and high-temperature conditions. Chart for determining economical amount of insulation. Amounts of coal, heat and money saved by insulation. Paper read before Am. Inst. Chem. Engrs.

INTERCHANGEABLE MANUFACTURE

Machined Fits. An Analysis of Machined Fits. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 132–133 and 144, 12 figs. Questionnaire being sent to manufacturers by Subcommittee on Standards and Tolerances for Manufactured Material, and sectional committee on Plain Limit Gages for General Engineering Work, a sectional committee which is working under Rules of Procedure of Am. Eng. Standards Committee and is sponsored by Am. Soc. Mech. Engrs.

INTERNAL-COMBUSTION ENGINES

Drayton. The Drayton Two-Stroke Engine. Automobile Engr., vol. 11, no. 146, Jan. 1921, pp. 14–15, 7 figs. Experimental supercharging unit.

Fatigue of. Criterion for Determining Fatigue of Internal-Combustion Engines (Au sujet de la détermination d'un critère de fatigue générale des moteurs à combustion interne), M. Dumanois. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 1, Jan. 3, 1921, pp. 44–46. Coefficient of general fatigue is expressed in terms of variations of temperature of inside wall of cylinder.

Fuels for. Oils for Internal Combustion Engines, J. L. Chaloner. Trans. Inst. Mar. Engrs., vol. 32, Dec. 1920, pp. 215–232, 8 figs. Comparative study of suitability of fuels used.

Testing of Oils for Internal Combustion Engines, Tom McKenzie. Trans. Inst. Mar. Engrs., vol. 32, Dec. 1920, pp. 232–247 and (discussion) pp. 247–250, 6 figs. Tests required in specifications of internal-combustion engine fuels.

Marine. Six-Cylinder Petrol or Paraffin Marine Motors. Engineering, vol. 111, no. 2876, Feb. 11, 1921, pp. 168–169, 13 figs. on supp. plate. Gleniffer motors built with 1, 2, 4 or 6 cylinders, cylinder dimensions in each case being 6 in. bore by 8 in. stroke.

[See also DIESEL ENGINES; DYNAMOMETERS; GAS ENGINES; GAS TURBINES; MOTORCYCLES, Engine for; OIL ENGINES; TRACTOR ENGINES.]

IRON

Electrolytic. Some Aspects of Electrolytic Iron, W. Albert Noyes, Jr., Thirty-Ninth General Meeting Am. Electrochemical Soc., April 21–23, 1921, 7 pp. Experimental measurement of minimum potential at which electrolytic deposition of iron can be carried out.

L

LABOR

Three-Shift vs. Two-Shift System. The Three-Shift System in the Steel Industry, Horace B. Drury. Bul. Taylor Soc., vol. 6, no. 1, Feb. 1921, pp. 2–49. Survey of conditions in some 20 American steel mills where change from two-shift to three-shift has been introduced, with notes on introduction of three-shift system almost exclusively in European and English steel works. Paper read at joint meeting of Taylor Soc., Metropolitan and Management Section of Am. Soc. of Mech. Engrs. and New York Section, Am. Inst. Elec. Engrs.

LABORATORIES

U. S. Navy. The New U. S. Naval Experimental and Research Laboratory, Havelock C. Hislop. Compressed Air Mag., vol. 26, no. 2, Feb. 1921, pp. 9973–9974. Laboratory under erection at Belleville, D. C. where civilian scientists and engineers, represented through Naval Consulting Board will have opportunity to engage in research work for benefit of navy.

LADLES

Drying. Drying 100-Ton Ladles, Alan E. Dynan, Iron Age, vol. 107, no. 6, Feb. 10, 1921, p. 394. 1 fig. Swinging-type burner using preheated tar without artificial air supply.

LATHES

Automatic. The Hartness Automatic Lathe. Am. Mach., vol. 54, no. 7, Feb. 17, 1921, pp. 273–275, 7 figs. Machine intended for large production. Head placed at angle. Groups of tools carried by two bars. All movements controlled by single cam-drum.

The Hartness Automatic Lathe. Iron Age, vol. 107, no. 6, Feb. 10, 1921, p. 386, 1 fig. Designed to handle boring, turning and facing cuts in pieces under 12 in. in diameter and 6 in. in length.

Turret. Turret Lathe Applications, J. H. Moore. Can. Machy., vol. 25, no. 6, Feb. 10, 1921, pp. 38–41, 15 figs. Tooling necessary for machining engine cylinder, clutch cone, clutch cone gear, and peculiar-shaped tractor driving-axle arm.

LIGHTING

Factory. Present Day Illumination Standards, George C. Cousins. Jl. Eng. Inst. of Canada, vol. 4, no. 2, Feb. 1921, pp. 105–109, 7 figs. Relations between good lighting and increased efficiency, with tables showing results of better lighting in factory.

LIGNITE

Combustion. Combustion of Lignites and High-Moisture Fuels, T. A. Marsh. Combustion, vol. 4, no. 2, Feb. 1921, pp. 39–44, 7 figs. Methods of burning these fuels and results in their combustion. Paper read before Stoker Manufacturers' Assn.

LOCOMOTIVES

Design. Locomotives and Rolling Stock of 1920. Engr., vol. 131, no. 3393, Jan. 7, 1921, pp. 10–12 and 14, 6 figs. Survey of recent developments in design.

Electric. See ELECTRIC LOCOMOTIVES.

Feedwater Treatment. Railway Water Treatment Pays Large Returns, Paul M. LaBach. Ry. Age, vol. 70, no. 3, Jan. 21, 1921, pp. 247–248, 2 figs. Results obtained by Rock Island system.

Manufacture. Methods in a Locomotive Works. Eng. Production, vol. 2, no. 15, Jan. 13, 1921, pp. 55–64, 34 figs. Practice of Midland Railway Co., England.

Oil-Burning. Experience of a French Railway with Oil Burning Locomotives (Note sur les premiers essais a la compagnie d'orléans du chauffage des foyers de locomotives au "fuel oil"), Louis Bigourat. Revue generale des Chemins de Fer, vol. 40, no 1, Jan. 1921, pp. 9–32, 10 figs. Apparatus employed and results obtained. Comparison with coal burning locomotives.

Reconstruction. Practical Reconstruction of Old Locomotives. Ry. Age, vol. 70, no. 3, Jan. 21, 1921, pp. 237–240, 6 figs. Typical examples of reconstruction work.

Squaring Valves. A Short Cut in Squaring Locomotive Valves, William Ulrick. Ry. Mech. Engr., vol. 95, no. 2, Feb. 1921, pp. 123–124, 4 figs. Squaring valves without applying main rods and afterwards removing them.

LUBRICANTS

Tests. Flash and Fire Tests, their Importance. Lubrication, vol. 6, no. 11, Dec. 1920, pp. 9–12, 1 fig. Standard instruments for testing lubricants and methods of operation.

Viscosity. Tentative Lubricant Viscosity Progresses. Sci. Lubrication, vol. 1, no. 1, Jan. 1921, pp. 9 and 32. Tentative test for viscosity of lubricants adopted by Am. Soc. for Testing Matls.

Worm-Gear Efficiency. The Effect of Lubricants Upon Worm-Gear Efficiency, J. H. Hyde. Eng. & Indus. Management, vol. 5, no. 2, Jan. 13, 1921, pp. 46–48. Report of Lubricant & Lubrication Inquiry Committee of British Department of Scientific & Industrial Research.

LUBRICATING OILS

Carbonization. Carbonization of Lubricating Oils. Dept. of Commerce, Circular of Bur. of Standards, no. 99, Nov. 12, 1920, 44 pp. 4 figs. Nature of effects of deposits formed in internal combustion engines. It is known that term "carbon" is a misnomer, because deposits consist largely of asphaltic matter. Accounts are given of nature of petroleum oils and of theories concerning formation of deposits.

The Carbonization of Lubricating Oils in Internal-Combustion Engines, Frederic H. Garner. Petroleum Times, vol. 5, no. 107, Jan. 22, 1921, pp. 93–95. Requirements of lubricating oils which will reduce carbonization in cylinder of internal-combustion engine to minimum. (Abstract.) Paper read before Instn. Petroleum Technologists.

Cold Test. A Cold Test Apparatus for Oils, G. H. P. Lichthardt. Jl. Indus. & Eng. Chem., vol. 13, no. 2, Feb. 1921, pp. 145–146, 1 fig. Apparatus used for lubricating oils at laboratory of Southern Pacific Railroad Co.

Testing Machine. Friction and Lubrication, R. Mountford Deeley. Engr., vol. 131, no. 3395, Jan. 21, 1921, p. 78, 1 fig. Deeley's oil-testing machine. Preliminary report communicated to Lubricants & Lubrication Inquiry Committee of Dept. of Sci. & Industrial Research.

M

MACHINE CONSTRUCTION

Economics. The Relationship between Design, Construction and Economics in Machine Construction (Der Zusammenhang von Gestaltung, Fertigung und Wirtschaftlichkeit im Maschinenbau), G. Schlesinger. Betrieb, vol. 3, no. 7, Jan. 10, 1921, pp. 177–187, 10 figs. Introductory address to lecture on machine construction in the Technical Academy, Charlottenburg.

MACHINE TOOLS

Alignment. Correcting the Alignment of Machine Tools, F. Horner. Can. Machy., vol. 25, no. 4, Jan. 27, 1921, pp. 33–37, 12 figs. Methods of correcting alignment of spindles, slides, heads, cylindrical bearings, clamping devices, turrets and other parts of machine tools.

British. Notes on Improvements in British Machines, J. William Chubb. Am. Mach., vol. 54, no. 4, Jan. 27, 1921, pp. 141–145, 12 figs. Ten new types produced in last ten years. Changes in machine details. Special vs. general-purpose machines. Unusual planer drive.

Clamping Devices. Design, Fabrication and Use of Clamping Devices (Ueber Konstruktion, Herstellung und Verwendung von Spanneisen), Guido Dierauer. Werkstattstechnik, vol. 15, no. 2, Jan. 15, 1921, pp. 33–39, 26 figs. Deals with various types of devices for clamping work in boring mills, lathes, milling machines, etc.

Manufacture. Tool Plant Reflects New Ideas, Dann O. Taber. Iron Trade Rev., vol. 68, no. 5, Feb. 3, 1921, pp. 344–349, 11 figs. Description of machine tool plant in Cleveland, noting arrangements of equipment and facilities for handling materials.

Performance Record. Apparatus for Recording the Performance of Machine Tools (Ueber Kontrollschreibapparate für Arbeitsleistungen an Werkzeugmaschinen), F. Breitling. Werkstattstechnik, vol. 15, no. 2, Jan. 15, 1921, pp. 43–44, 5 figs. Details of the work-recording clock originally designed and employed by Dr. Poppelreuter in his nerve clinic for wounds in the head; curves recorded with this clock are said to give an excellent presentation of the efficiency of a workman as well as of the useful scope of a machine tool. Description of Harms control apparatus for recording operations of machine tools, etc.

Repetition Work. Machining Operations on Repetition Work—Part I. Eng. Production, vol. 2, no. 16, Jan. 20, 1921, pp. 76–81, 15 figs. Examples of modern practice in construction and operation of machine tools.

Safeguards. Guarding Machine Tools. Mech. World, vol. 69, no. 1775, Jan. 7, 1921, pp. 4–5. Forms and types of safe guards. (Abstract.) Paper read before Industrial Safety Conference organized by the Home Office and British Industrial "Safety First" Association.

The Safeguarding of Machinery. Foundry Trade Jl., vol. 23, no. 230, Jan. 13, 1921, pp. 34–35. Forms and types of safeguards. (Abstract.) Paper read before Industrial Safety Conference organized by Home Office & British Industrial "Safety First" Association.

Working Speeds. Standardized Calculation of Working Speed (Einheitliche Laufzeitberechnung), A. Winkel. Werkstattstechnik, vol. 15, no. 1, Jan. 1, 1921, pp. 5–10, 10 figs. Reduction of the working-speed equation for the different machining operations to a uniform equation, correction of this equation for planing based on diagrams for planers, its use for the design of a slide rule, and the development and manipulation of described slide rule.

MALLEABLE IRON

Cupola-Melted. Experiments on Cupola Malleable, F. H. Hurren. Foundry, vol. 49, no. 4, Feb. 15, 1921, pp. 135–138, 6 figs. Comparative study of cupola melted metal and air furnace product. Paper read before Birmingham Branch, Instn. British Foundrymen.

Metallography. American Malleable Cast Iron—III, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 5, Feb. 3, 1921, pp. 353–357 and 361, 9 figs. Metallography of malleable iron.

Properties. American Malleable Cast Iron—IV, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 7, Feb. 17, 1921, pp. 485–488, 7 figs. Tensile properties of malleable iron.

MANGANESE STEEL

Magnetic Mechanical Analysis. The Magnetic Mechanical Analysis of Manganese Steel, Robert Hadfield and S. R. Williams and I. S. Bowen. Proc. Royal Soc., vol. 98, no. A692, Jan. 3, 1921, pp. 297–302, 3 figs. Correlation of magnetic and mechanical properties of manganese steel.

MARINE BOILERS

Return-Tube. Cylindrical Return-Tube Boilers, W. F. Carnes. Gen. Elec. Rev., vol. 24, no. 2, Feb. 1921, pp. 110–114, 7 figs. Their manufacture by Bethlehem Shipbuilding Corp.

Water-Tube. Water Tube Marine Boilers, W. M. McFarland. Gen. Elec. Rev., vol. 24, no. 2, Feb. 1921, pp. 115–119, 4 figs. Evolution and adoption of Babcock & Wilcox stationary boiler to render it suitable for use on board ship.

[See also BOILERS, WATER-TUBE.]

MEASURING INSTRUMENTS

Tolerances. Weights and Measures. Dept. of Commerce, Bur. of Standards, miscellaneous publications, no. 43, 1921, 200 pp. Specifications and tolerances of measuring instruments. Thirteenth annual conference of representatives from various states held at Bur. of Standards, Washington, D. C., May 24–27, 1920.

METALS

Calorizing. Calorizing as a Protection for Metals, Arthur V. Farr. Iron Age, vol. 107, no. 4, Jan. 27, 1921, pp. 251–253, 9 figs. General Electric Co. process of protecting methods at high temperatures. Process consists in placing material to be calorized in retort and heating in reducing atmosphere, retort being filled with mixture containing finely divided aluminum. Treatment infuses aluminum into exposed portion of metal so as to form homogeneous aluminum alloy for certain depth.

Finish. Finish of Metallic Materials, Sidney Cornell. Chem. & Metallurgical Eng., vol. 24, no. 5, Feb. 2, 1921, pp. 209–212. Quality given by heat treatment contrasted with durability and appearance. Finish of metallic materials discussed as essential detail in modern manufacturing, with brief notes on cleaning, polishing, lacquering, coatings, slushes and wrapping.

METRIC SYSTEM

Arguments Against Adoption in U. S. Metric Bugaboo Again in Congress, C. C. Stutz. Am. Industries, vol. 21, no. 7, Feb. 1921, pp. 19–21, 2 figs. Criticism of bill for adoption of Metric system in U. S. introduced into Senate. Map of the world is presented and "commanding position of the English system" is indicated.

MILLING CUTTERS

Standards. British Standards for Milling Cutters and Reamers. British Eng. Standards Asso., no. 122, July 1920, 67 pp. 46 figs. Standards for non-relieved cutters, end mills, form-relieved cutters and reamers, determined as result of conference, research and coöperation between small tool makers, machine-tool makers and users of these tools in Great Britain.

MILLING MACHINES

Manufacture. Making One Thousand Milling Machine Saddles, Donald A. Hampson. Can. Machy., vol. 25, no. 6, Feb. 10, 1921, pp. 33–37, 15 figs. Equipment necessary to produce one thousand saddles every year. Pattern work is taken up, also various machining operations, cost of machine tools and other vital points.

Profile. Profile Milling. Eng. Production, vol. 2, no. 18, Feb. 3, 1921, pp. 170–172, 8 figs. Automatic profile-milling machine.

MOLDING MACHINES

Hand-Power. Hand-Power Moulding Machine. Engineering, vol. 111, no. 2876, Feb. 11, 1921, pp. 164–166, 16 figs. Designed to be easily adjusted to take boxes and pattern plates of any size within comparatively wide range.

Suspended-Type. Inventor Installs His Own Devices. Foundry, vol. 49, no. 3, Feb. 1, 1921, pp. 98–103, 12 figs. Adaptation of molding machine through suspending it and carrying it along molding floor. Installation at foundry of Standard Malleable Iron Co., Muskegon, Mich.

MOLDS

Foundry, Drying. The Drying of Foundry Molds and Cores Through Electrically Preheated Air (Trocknung der Formen und Kerne in der Giesserei durch elektrisch vorgewärmte Luft). Zeit. für die gesamte Giessereipraxis, vol. 42, no. 4, Jan. 22, 1921, pp. 50–51. Describes electric-hot-air apparatus of the Oerlikon Machine Factory, advantages of which over other heating methods with solid fuel are pointed out.

MONEL METAL

Properties. Monel Metal—II, Adolph Bregman. Metal Industry (N. Y.), vol. 19, no. 2, Feb. 1921, pp. 64–65, 4 figs. Summary of properties, methods of melting and casting, uses, handling and working in up-to-date practice of this natural nickel alloy.

Notes on Monel Metal, Paul D. Merica. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 291–294, 3 figs. Physical properties of this natural alloy, and commercial uses to which it has been adapted. Its resistance to corrosion and its strength at high temperatures are perhaps most useful properties.

MOTOR TRUCKS

American-Made. Complete Mechanical Specifications of All Makes of 1921 Gasoline Motor Trucks. Motor Age, vol. 39, no. 4, Jan. 27, 1921, pp. 90–105. Details of 527 gasoline and one steam motor-truck chassis as produced by 176 American truck manufacturers.

New York Show. Observations at the New York Truck Show, P. M. Heldt. Automotive Industries, vol. 44, no. 3, Jan. 20, 1921, pp. 119–123, 13 figs. Few changes of radical nature in evidence. Influence of war designs seen in fitting of bumpers and tow hooks on many models.

Steam. Steam Waggon Construction. Eng. Production, vol. 2, no. 18, Feb. 3, 1921, pp. 162–168, 15 figs. Methods at Sentinel Waggon Works, England.

The Application of Steam Power to an Automotive Truck, Lewis L. Scott. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 155–160 and 162, 9 figs. Steam engine used on two-ton truck. Characteristic torque curves of 40-hp. internal-combustion engine and steam engine developing same power.

Three-Point-Mounted. Three Point Chassis Mounting Feature of New Speed Truck. Automotive Industries, vol. 44, no. 5, Feb. 3, 1921, pp. 204–206, 6 figs. Midwest engine with two-bearing crankshaft and full electrical equipment is rigidly mounted on two forward points but has flexible connection with frame at rear supports. Rigid frame designed to prevent weaving of bodies.

MOTORCYCLES

Engine for. An Aluminum Motorcycle Engine. Automotive Industries, vol. 44, no. 6, Feb. 10, 1921, p. 258, 1 fig. V type with two-cylinders cast together with top half of crankcase of aluminum. Translated from Motorwagen.

MOTORSHIPS

Economical Advantages. Motorships, Charles Edward Lucke. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 140–141. Economical advantages of motorship. Construction of motorships by European shipbuilding nations and its continued adoption in U. S.

Europe. A Review of Motorship and Marine Diesel Engine Building in Europe. Mar. Eng., vol. 26, no. 1, Jan. 1921, pp. 49–54, 4 figs. During 1920 about 20 large motorships were completed and orders in hand in European yards at beginning of 1921 amount to between 180 and 190 ships, varying from vessels of 14,000 tons deadweight capacity to craft of 3,500 tons, total deadweight capacity being estimated at 1,500,000 tons.

United States. Motorship Building in the United States. Mar. Eng., vol. 26, no. 1, Jan. 1921, pp. 46–48. Nineteen motorships, totalling 143,850 deadweight tons, under construction in U. S. at beginning of 1921, total shaft horsepower of vessels amounting to 44,520.

N

NICKEL

Properties. Chemical Properties and Metallography of Nickel, Paul D. Merica. Chem. & Metallurgical Eng., vol. 24, no. 5, Feb. 2, 1921, pp. 197–200, 4 figs. Data on solubility and magnetic transformation of pure nickel; also on effect of common impurities such as carbon, oxygen, manganese, sulphur, cobalt, iron and silicon upon various physical properties.

NICKEL-CHROME STEEL

Properties. Nickel-Chrome Steels. Machy. (Lond.), vol. 17, no. 433, Jan. 13, 1921, pp. 465–467. Chart showing tensile strength of nickel-chrome oil-hardening steel.

NOZZLES

Steam, Tests of. German Tests on Steam Nozzles and Diffusors. Steam, vol. 27, no. 1, Jan. 1921, pp. 8–9, 1 fig. Experiments carried out in laboratory of machine design of Technical High School, Charlottenburg, Germany. Translated from Zeitschrift des Vereines deutscher Ingenieure.

The Best Production Methods Are the Most Economical

There is only one *best* method in turret lathe practice. Our Engineers are constantly studying and experimenting to reach that best method and keep our turret lathes up to their high standard.

The results of their study and experimenting are yours to apply to your production problems. Just write us and we'll send one of our engineers to consult with you. He may be able to save you considerable money by suggesting a tool or two or perhaps by re-arranging the tools you have. This is part of our service to you.

Turret Lathes from 4½" x 44"—21" Swing to ⅝" x 4"—10" Swing.

A. W. & S. No. 3-A finishes one of these Air Brake Pump Pistons of cold rolled stock every 20 minutes in an eastern railroad shop. This is a difficult railroad job.

ENGINEERING INDEX (Continued)

O

OFFICE MANAGEMENT

Correspondence Filing. Some Suggestions on Office Correspondence Filing, Grant Gibson. Ry. Age, vol. 70, no. 7, Feb. 18, 1921, pp. 413–416, 5 figs. General, unit and sub-files and file book for cross reference facilitate locating letters.

OIL

Crude. Properties of Typical Crude Oils from the Eastern Producing Fields of the United States, E. W. Dean. Reports of Investigations, Dept. of Interior, Bur. of Mines, serial no. 2202, Jan. 1921, 57 pp. Specific gravity at 60 deg. fahr., sulphur percentage, water percentage, distillation at atmospheric pressure, vacuum distillation of residuum at 40 mm. absolute and Conradson carbon residue percentages.

[See also PETROLEUM.]

OIL ENGINES

Ingersoll-Rand. A New Development of the Heavy Oil Engine, F. A. McLean. Can. Machy., vol. 25, no. 3, Jan. 20, 1921, pp. 37–40, 4 figs. Principle of operation and structural details of Ingersoll-Rand, Price Rathbun type of heavy-oil engine.

Marine. 130-B. H. P. Bolnes Marine Oil Engine. Engineering, vol. 111, no. 2873, Jan. 21, 1921, pp. 70–72, 7 figs. Two-cycle hot-bulb Dutch-type engine resembling in general arrangement a steam marine engine.

Pistons. Casting and Machining Oil-Engine Pistons, Piston Rings and Cylinders, Samuel Rosswell. Am. Mach., vol. 54, no. 4, Jan. 27, 1921, pp. 137–140, 2 figs. Selection of materials. Vertical casting preferable. Heat treatment after rough-machining. Fitting piston pin. Assembling rings. Reaming vs. grinding cylinders.

Solid-Injection. Effect of Fuel Consumption on Oil-Engine Reliability, Ralph Miller. Power, vol. 53, no. 7, Feb. 15, 1921, pp. 272–273, 1 fig. Diagram from solid-injection engine.

OIL FIELDS

Exploitation by Shafts and Galleries. The Exploitation of Petroleum by Shafts and Galleries (De l'exploitation du pétrole par puits et galeries), N. A. Lykiardopoulo. Revue universelle des mines, vol. 8, no. 1, Jan. 1, 1921, pp. 38–45 Methods followed in exploitation of oil at Béchelbronn, Alsace.

The Exploitation of Petroleum by Shafts and Galleries (Exploitation de pétrole par puits et galeries), Paul de Chambrier. Pamphlet published by Dunod, editor, successor to H. Dunod & E. Pinat, 47 & 49, Quai des Grands-Augustins, 1921, 106 pp. 4 figs. Economical and technical advantages over drilling methods.

OIL FUEL

Coal vs. The Use of Fuel Oil as Compared with the Firing of Coal by Means of Mechanical Stokers, F. H. Daniels. Steam, vol. 27, no. 1, Jan. 1921, pp. 5–8, 1 fig. Urges prohibiting use of oil fuel on land and restricting it to ships. Graph giving comparative fuel costs of coal and oil fuel.

Installations. Unusual Efficiencies in an Oil Fuel Installation, Joseph Poke and Frank G. Philo. Universal Engr., vol. 33, no. 1, Jan. 1921, pp. 29–33, 3 figs. Oil-burning tests results obtained at plant of Savannah Electric Co. From Stone & Webster Jl.

Locomotives. Experimental Study of Oil-Fuel Burning in Locomotive Boilers (Resultati degli esperimenti e delle prove di trazione eseguite con alcune locomotive attrezzate per bruciare la nafta nei forni delle loro caldaie), Alessandro Mascini. Rivista tecnica delle Ferrovie Italiane, vol. 18, no. 4, Oct. 1920, pp. 117–126, 5 figs. Adoptation of locomotives to oil burning by Italian State Railways. (To be continued.)

Uses. Fuel Oil, W. A. White. North-East Coast Instn. Engrs. & Shipbuilders, Advance paper, 23 pp. 4 figs. Uses of oil fuel, particularly in ships, notes on fire precautions and appliances, with data on world oil deposits and probable resources.

OIL SHALES

Industry. A Review of the Progress of the Oil Shale Industry in 1920, Victor C. Alderson. Am. Gas Eng. Jl., vol. 114, no. 4, Jan. 22, 1921, pp. 69–71 and 79–81. Progress in utilization of oil shale.

Retorting. American vs. Scotch Methods in Retorting of Petro-Shales, J. B. Jenson. Salt Lake Min. Rev., vol. 22, no. 20, Jan. 30, 1921, pp. 17–23, 12 figs. Pumpherston and Henderson types of retorts.

Experimental Shale Oil-Retorting Plant. Chem. & Metallurgical Eng., vol. 24, no. 7, Feb. 16, 1921, pp. 312–313, 3 figs. 15-ton commercial unit installed by Shale Oil Refining Corp. at Denver, Col., using Johns eduction process.

OPEN-HEARTH FURNACES

Controlling Valve for. A New Type of Controlling-Valve for Supplying Air and Gas Mixtures to Open-Hearth Furnaces, W. H. Wharton. Iron & Steel of Canada, vol. 4, no. 1, Feb. 1921, pp. 18–20, 3 figs. Reversing valve combined with air-pressure and volume-controlling mechanism.

P

PAINTING

Spray. Recent Developments in Spray Painting, Henry A. Gardner. Paint Manufacturers' Assn. of U. S., circular no. 114, Jan. 1921, 18 pp. 20 figs. Paper read before Pennsylvania State Assn. of Master Painters.

PATTERNMAKING

Shop Organization. New England Pattern Shop is Unique, Herbert R. Simonds. Foundry, vol. 49, no. 4, Feb. 15, 1921, pp. 127–132, 13 figs. Plant is arranged as series of producing units each with its equipment complete. Progress of work is recorded by special system.

PEAT

Deposits. Classification and Formation of Peat and Related Deposits, C. C. Osbon. Jl. Am. Peat Soc., vol. 14, no. 1, Jan. 1921, pp. 37–44, 4 figs. Distinction between peat and muck. Theory of formation of deposits.

Gasoline from. Easy Money from Peat. Chem. & Metallurgical Eng., vol. 24, no. 5, Feb. 2, 1921, pp. 213–215, 1 fig. Apparatus and supertechnical process used for extracting methyl alcohol and gasoline out of peat.

Industry. News of the Industry in Foreign Countries. Jl. Am. Peat Soc., vol. 14, no. 1, Jan. 1921, pp. 31–36. British Empire, Denmark, France, Germany, Russia and Sweden.

News of the Domestic Industry. Jl. Am. Peat Soc., vol 14, no. 1, Jan. 1921, pp. 15–30. Developments of peat industry in different states.

Production in 1919. Production of Peat in 1919, K. W. Cottrell. Jl. Am. Peat Soc., vol. 14, no. 1, Jan. 1921, pp. 7–14. Total production in U. S. in 1919 was 69,197 short tons valued at $705,532.

PETROLEUM

Products, Testing. Use of the MacMichael Viscosimeter in Testing Petroleum Products, W. H. Herschel. Reports of Investigations, Bur. of Mines, Dept. of Interior, serial no. 2201, Jan. 1921, 12 pp. Conditions under which MacMichael torsion viscosimeter may be used to advantage in petroleum laboratory. Methods of operation and calibration.

PIPE LINES

Steam. Long Distance High-Pressure Steam Line. Power Plant Eng., vol. 25, no. 3, Feb. 1, 1921, pp. 157–159, 9 figs. Lines carry steam on pressure of 175 lb. per sq. in. total distance of about 3000 ft.

PLANERS

Toolroom. Gorton Toolroom Planer, J. V. Hunter. Am. Mach., vol. 54, no. 7, Feb. 17, 1921, pp. 257–259, 3 figs. Especially designed for work on dies, jigs and fixtures. Built in two sizes. Furnished with side head. Special features and specifications.

PLYWOOD

Screw Fastenings. Strength Tests of Screw Fastenings of Plywood, H. S. Grenoble. Aerial Age, vol. 12, no. 21, Jan. 3, 1921, pp. 535–536. Tables showing screws required for maximum strength, based on tests carried out at Forest Products Laboratory, Madison, Wis.

POLES, STEEL

Latticed. Calculations of Latticed Poles of Minimum Weight (Calcolo rapido dei pali a traliccio di peso minimo), Marco Semenza. Elettrotecnica, vol. 7, no. 36, Dec. 25, 1920, pp. 640–645, 3 figs. Design equations and graphs.

PORTS

New York, Reorganization of. Proposed Reorganization of the Port of New York. Ry. Age, vol. 70, no. 4, Jan. 28, 1921, pp. 269–274, 3 figs. Special automatic-electric subway recommended by New York-New Jersey Port and Harbor Development Commission.

POWER GENERATION

Gas vs. Electricity. Note on the Thermal Efficiency of the Generation and Use of Gas and Electricity, Dugald Clark. Jl. Instn. Elec. Engrs., vol. 28, no. 295, Sept. 1920, pp. 765–767 and (discussion), pp. 767–779, 1 fig. Ratio of utilized heat units by electricity into utilized heat units by gas for power purposes was found in experiments to be 1.6. This ratio was 4 for heat production and 0.84 for light.

Thermal Springs. The Utilization of Thermal Springs as Source of Energy (L'emploi des eaux thermales comme source d'énergie), P. Caufourier. Génie Civil, vol. 78, no. 2, Jan. 8, 1921, pp. 37–39, 2 figs. Installation at Hammam-Meskoutine, Algiers.

POWER PLANTS

Accounting. Armour System of Power-Plant Accounting, O. A. Anderson. Power, vol. 53, no. 4, Jan. 25, 1921, pp. 128–131, 1 fig. System of records and accounting from which cost figures are deduced and analyses made of plant operations. Motive-power department has under its supervision 72,000 hp. in boilers burning nearly 900,000 tons of coal and 700,000 bbl. of oil per year.

POWER TRANSMISSION

Hydraulic. Hydraulic Transmission of Power (La transmission hydraulique), A. Raudot. Revue généralé de l'Electricité, vol. 9, no. 5, Jan. 29, 1921, pp. 143–147, 4 figs. Technical study of principles of transmission of power by means of fluid, and survey of mechanisms which have been developed for this purpose. (To be continued.)

PRESSES

Feeding Devices. Littell Automatic Punch-Press Feeding Devices, J. V. Hunter. Am. Mach., vol. 54, no. 6, Feb. 10, 1921, pp. 209–212, 9 figs. Automatic feed to increase output and safeguard workmen. Construction of attachments for feeding from roll. Dial, slide and hopper feeding mechanisms.

PRESSWORK

Universal-Joint Covers. Making a Sheet-Steel Universal Joint Cover, W. A. Flumerfelt. Am. Mach., vol. 54, no. 5, Feb. 3, 1921, pp. 171–173, 9 figs. Methods of drawing and forming articles of comparatively thick sheet metal. Flanging and closing-in by means of sectional dies.

PROFIT SHARING

England. A History of Profit Sharing in the British Isles, W. Wallace. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 85–89. Analysis and summary of recent report by English Ministry of Labor.

Experiences. Promoting Efficiency in Industrial Plants. Iron Age, vol. 107, no. 4, Jan. 27, 1921, p. 267. Cleveland Chamber of Commerce publishes results of survey of 600 companies and study of profit sharing in various forms.

Legislation. Profit Sharing in France (La participation ouvriére aux bénéfices de la production), Paul Razous. Génie Civil, vol. 78, no. 3, Jan. 15, 1921, pp. 59–61. Survey of legislation and practices in Government establishments. (To be continued.)

PULVERIZED COAL

Boiler Firing. Engineers Afforded Latest Information on Powdered Coal and Briquets, R. Dawson Hall. Coal Age, vol. 19, no. 1, Jan. 6, 1921, pp. 16–17. Results of boiler trials made at pulverized fuel plant, Lykens, Pa.

Some Comments on Pulverized Coal for Power Plants, Frederick A. Scheffler. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 1, Jan. 1921, pp. 7–13, 3 figs. Typical applications of pulverized coal to Babcock & Wilcox boiler and to Stirling boiler.

Heating Furnaces. Experience with Powdered Coal for Heating Furnaces, Charles Longenecker. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 86–88, 4 figs. Advantages of powdered coal for heating and forging furnaces.

Quigley System. Pulverized Coal, Ralph H. Cridge. Elec. Times, vol. 59, no. 1526, Jan. 13, 1921, pp. 25–28, 7 figs. Quigley system of burning pulverized coal.

Tests. Actual Performance of Powdered Coal, Chas. Longenecker. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 59–61. Results obtained in number of recent tests.

PUMPING PLANTS

Argentina Naval Port. The Dock Pumping Plant in the Argentine Naval Port, Puerto Militar (Die Dockpumpenanlage im argentinischen Kriegshafen Puerto Militar), H. Wiegieb. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 4, Jan. 22, 1921, pp. 89–92, 6 figs. Notes on general arrangement, main and bilge pumps, steam-boiler plant, electric and hydraulic powerhouse, operating results and comparison with other plants. Plant with all auxiliary equipment was installed by Haniel & Lueg, Düsseldorf, Germany.

PUMPS

Automatic Valves for. Investigation of Automatic Pump Valves and Their Effect on Pumping (Untersuchung selbsttätiger Pumpenventile und ihrer Einwirkung auf den Pumpengang), Ludwig Krauss. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 5, Jan. 29, 1921, pp. 116–122, 23 figs. With a view to eliminating the loud beating of pump valves and securing perfect flow conditions, writer made investigation of six modern valves under widely different working conditions, results of which show that the valve construction exercises less influence than size. Determination of values of discharge and resistance of four valves.

PUMPS, CENTRIFUGAL

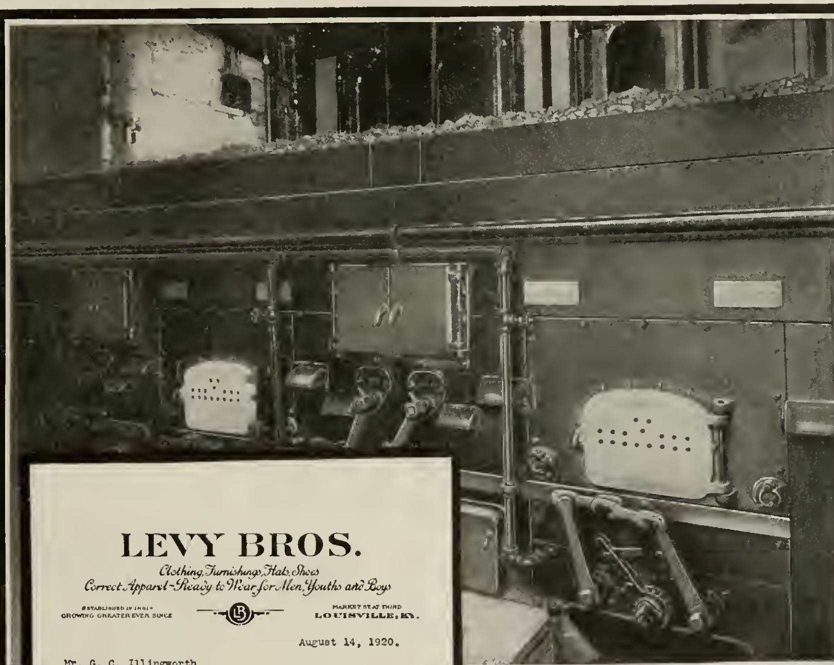
$35.00 Maintains 2 Stokers For 10 Years



LEVY BROS.

Clothing, Furnishings, Hats, Shoes
Correct Apparel — Ready to Wear for Men, Youths and Boys

ESTABLISHED IN 1861 — GROWING GREATER EVER SINCE — MARKET ST. AT THIRD — LOUISVILLE, KY.

August 14, 1920.

Mr. G. C. Illingworth,
c/o Murphy Iron Works,
#1232 Union Trust Bldg.,
Cincinnati, O.

Dear Sir:

Your letter of August 12th to hand, and I am very glad to have the opportunity to express my opinion regarding the two Murphy Stokers, under 150 H. P. boilers, I have had in my charge since 1910.

During the first four years I was making steam for two engines at a rate of 13 hours per day, during the last six years for heating the building in cold weather. I have the satisfaction to say that during the entire time of ten years I lost one grate bar. I have to this date the first arches, clinker rolls and other parts of stokers in good condition.

As to the maintaining expense of your two stokers, I will say that $35. would cover everything, including fire brick and fire clay for door linings.

It always gives me pleasure to speak well for any good machine I have had during my forty years experience, and for your stokers I cannot say enough.

Hoping this record will be of some interest to you, I beg to remain,

Yours truly,
R. T. Reinsperger, E.
Levy Bros.

Performance over a period of 10 years such as is indicated in the letter reproduced herewith speaks well not only for the design and construction of the

MURPHY AUTOMATIC FURNACES

but equally as well for good operation on the part of the Chief Engineer.

If you hesitate about installing stokers because you fear large repair bills, it will pay you to read carefully this letter.

To fully acquaint yourself with the design and construction of the Murphy Furnace which makes such records possible send for Catalog T-3.

"A type to meet every stoker need"

RESEARCH

Coördination in. Research Laboratory Adopts Modern Management, C. V. Maudlin. Indus. Management, vol. 61, no. 3, Feb. 1, 1921, pp. 98–102, 5 figs. Plan of record and control adopted at Forest Products Laboratory, U. S. Forest Service.

Government-Operated. Scientific and Engineering Work of the Government, E. B. Rosa. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 111–118, 6 figs. Survey of government research work and its economical significance and cost.

Industrial and Scientific. A Reading List on Scientific and Industrial Research and the Service of the Chemist to Industry, Clarence Jay West. Reprint & Circular Series of Nat. Research Council, no. 9, April 1920, 45 pp. Articles on industrial and scientific research.

Industrial Research, Frank B. Jewett. Reprint and Circular Series of Nat. Research Council, no. 4, 16 pp. Urges promotion of industrial research. Paper read before Royal Can. Inst.

Research Laboratories in Industrial Establishments of the United States of America, Alfred D. Flinn, A. J. Porskievies and Ruth Cobb. Bul. Nat. Research Council, vol. 1, part 2, no. 2, March 1920, pp. 45–130. Classified list with information on staff, work and equipment.

Research in Industrial Conservation, H. E. Howe. Gas Age, vol. 47, no. 2, Jan 25, 1921, pp. 42–44. Importance of research in securing increased production, conservation of supplies and selection of best materials and methods.

Machinery. Completes Laboratory for Research in Machinery. Iron Trade Rev., vol. 68, no. 2, Jan. 13, 1921, pp. 152–153, 4 figs. Mechanical laboratory designed for research work in machinery, installed at Nat. Lamp Works of Gen. Elec. Co., Cleveland.

Organization of. An Industrial Research Association, Arthur W. Crossley. Chem. Age (Lond.), vol. 4, no. 83, Jan. 15, 1921, pp 73–74. Advantages of coöperative laboratory research in industry.

The Organization of Research, William Morton Wheeler. Science, vol. 53, no. 1360, Jan. 21, 1921, pp. 53–67. Deprecates organization of research because research, to be successful, must be carried out in a manner to permit full development of personality and individual initiative, manifestations which cannot take place if investigator is merely a part of an organized mechanism.

RIVETING MACHINES

Electric. The Influence of Electrotechnology on Riveting (Das Nieten unter dem Einfluss der Elektrotechnik), H. Wintermeyer. Elektrotechnischer Anzeiger, vol. 38, no. 12, Jan. 22, 1921, pp. 55–58, 4 figs. Details of modern types of electric riveting machines, electrohydraulic riveting machines, electric rivet forges, etc.

RIVETS

Electric Heaters for. Electric Rivet Heaters. Ry. Engr., vol. 42, no. 492, Jan. 1921, pp. 23–24, 1 fig. Data on power consumption.

The Lecfur Automatic Electric Rivet Heaters, Practical Engr., vol. 63, no. 1769, Jan. 20, 1921, pp 36–38. Resistance-type furnace.

ROCK DRILLS

Electric. Electric Rock Drills for Mines and Quarries (Elektrische Bohrmaschinen im Betriebe von Bergwerken und Steinbrüchen), Friedrich Ludwig. Elektrotechnischer Anzeiger, vol. 38, nos. 9 and 10, Jan. 18 and 19, 1921, pp. 39–40 and 43–44, 15 figs. Describes types of hand and column machines.

ROLLING MILLS

Efficiency of. The Economics of Roll Trains, A. Dyckerhoff. Iron Trade Rev., vol. 68, no. 4, Jan. 27, 1921, pp. 279–282, 8 figs. Closer study of roll pass design as procedure to increase overall efficiencies of rolling mills.

Electric Drive. Electrical Review Steel Industry for 1920, G. E. Stolz. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 4–5. Steam driven mills rapidly being replaced by progressive application of electricity to steel mill drives. Number of instances shown where steam equipment is being replaced.

Recent Developments in Electric Mill Drive. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 93–94. Practically all new reversing mills built during 1920 are electrically driven mills. Most interesting reversing-mill drive of year built for Tata Iron & Steel Co., at Temshedpur, India.

Plate Mills. Rolls Ship Plates on New Mill, Joseph Horton. Iron Trade Rev., vol. 68, no. 6, Feb. 10, 1921, pp. 410–412, 4 figs. English works where product is transferred from hot bed to shears by movable runout table which controls plate while its ends are being trimmed.

Rotary Side-Cutting Shear for Three-High Plate Mill. Engr., vol. 131, no. 3397, Feb. 4, 1921, pp. 124 and 129–130, 8 figs. partly on supp. plate. Mill has top and bottom rolls 36 in. diameter and middle roll of 24 in. diameter, all 9 ft. long on barrel and is designed to roll plates from $^1/_8$ in. to $1^1/_2$ in. thick up to length of 60 ft. and maximum shearing width of 8 ft. 6 in., maximum weight of finished plate being 5 tons.

The Dominion Iron and Steel Company's New Ship Plate Rolling Mill, Barton R. Shover. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 80–84, 4 figs. Electrically driven mill in which electric motors are used for practically all work in plant.

Variable-Section Shapes. Continuous Die Forming, G. R. Norton. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 104–106, 4 figs. Also in Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 30–32. New process designed to roll variable section shapes at Neville Island plant of Witherow Steel Co. Products to be manufactured in alloy and special steels.

ROPES

Winding. Deformation in Winding Ropes, H. Herbst. Quarry, vol. 26, no. 287, Jan. 1921, pp. 17–21, 6 figs. Formulas for determining stresses. Translated from Glückauf.

S

SCREW MACHINES

Automatic. The Automatic Stopping of Screw Machines (Das selbsttätige Stillsetzen von Automaten), H. Bauer. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 5, Jan. 29, 1921, pp. 122–123, 11 figs. Points out desirability of automatic stopping and describes certain release devices for different makes of machines.

The "Empire" Full Automatic Screw Machine. Machy. (Lond.), vol. 17, no. 434, Jan. 20, 1921, pp. 492–493, 3 figs. English designs of automatic and pin and stud machines.

Circular Forming Tools. Design of Circular Forming Tools. Machy. (Lond.), vol. 17, no. 435, Jan. 27, 1921, pp. 517–520, 6 figs. Calculations for designing circular forming tools having top rake.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SEAPLANES

Design. Conditions of Flight of a Hydroplane (Etude sur les conditions d'envol de l'hydravion). Aérophile, vol. 28, nos. 23–24, Dec. 1–15, 1920, pp. 359–360, 6 figs. Technical determination of forces acting.

SHAFTS

Bending of. Theoretical Consideration of Bending in Shafts, Charles W. Good. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 138–139. Computation of pressure distribution of loads and reactions, and effect of various distributions

Critical Speeds. The Calculation of Critical Torsional Speeds (Beiträge zur Berechnung kritischer Torsions-Drehzahlen), Fr. Sass. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 3, Jan. 15, 1921, pp. 67–69, 9 figs. Describes method said to greatly simplify the tedious calculation of the critical torsional speed of multiple-crank engines. It is based on the combination of any number of small masses into a single equivalent mass of a given magnitude varying with the number of oscillations. Numerical tables are given for the rapid determination of the reduced length of cranked portion of shaft.

The Critical Speed of a Turbine Spindle, Richard Gardner. Engineering, vol. 111, no. 2874, Jan. 28, 1921, pp. 99–100, 1 fig. Method of obtaining formula for motor which is roughly symmetrical about its middle, taking common case of rotor formed by wheels carried on spindle, diameter of which is stepped.

Multiple-Splined. Torsional Strength of Multiple-Splined Shafts, C. W. Spicer. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 129–130 and 199, 4 figs. Comparative torsional tests of splined shafts and full round shafts.

SHIPBUILDING

1920. Naval Construction in 1920. Engr., vol. 131, no. 3393, Jan. 7, 1921, pp. 16–18. Statistics of shipbuilding throughout world.

The World's Mercantile Shipbuilding in 1920. Shipbuilder, vol. 24, no. 126, Feb. 1921, pp. 151–157, 1 fig. Statistics by countries.

United States. American Shipbuilding—Present and Future. Mar. Eng., vol. 26, no. 1, Jan. 1921, pp. 24–30, 2 figs. It is expected that by July 1, 1921 American merchant marine will aggregate 19,000,000 gross tons. Present tonnage is over 16,000,000 gross tons.

World Statistics. The World's Shipbuilding. Engineering, vol. 111, no. 2874, Jan. 28, 1921, pp. 102–103. Lloyd's statistics for 1920. Total production of world amounted to 7259 ships, making 5,861,666 gross tons as compared with 2483 ships and 7,144,549 tons in 1919.

SPRING MOTORS

Manufacture. Manufacturing Spring Motors—I. Machy. (Lond.), vol. 17, no. 436, Feb. 3, 1921, pp. 556–560, 10 figs. Time-saving methods used in machining phonograph motor parts.

SPRINGS

Calculations. Derivation of Formulæ for Spring Calculations. Machy. (Lond.), vol. 17, no. 434, Jan. 20, 1921, pp. 485–488, 3 figs. Illustrations of procedure in various cases.

STANDARDS

Automotive Industry. Standards Committee Meeting. Jl. Soc. Automotive Engrs., vol. 8, no. 2, Feb. 1921, pp. 169–199, 16 figs. Proposed standards for ball bearings, electrical equipment, engine parts, etc.

STEAM

Properties. The Properties of Steam. Engineering, vol. 111, nos. 2873 and 2874, Jan. 21 and 28, 1921, pp. 63–65 and 93–94, 1 fig. Review of Callender's work. Jan. 21: Thermodynamic theory of vapor and application of vapor conclusions to steam. Jan. 28: Properties of steam near critical point. (Concluded.)

STEAM-ELECTRIC PLANTS

Enlarging. Riverside Station Enlarged by 50,000 Kilowatts. Power, vol. 53, no. 2, Jan. 11, 1921, pp. 50–57, 12 figs. Additions to steam-electric plant in Minneapolis. Features are coal and ash handling, skylight illumination of boiler and turbine rooms, all-steel turbine foundations and truck-type oil switches to facilitate their exchange or removal for inspection or repairs.

ENGINEERING INDEX (Continued)

Germany. The Principal Defects in German Steam Plants and Their Elimination (Die hauptsächlichen Mängel unserer Dampfanlagen und ihre Beseitigung), H. Reischle. Zeit. des Bayerischen Revisions-Vereins, vol. 25, no. 1, Jan. 15, 1921, pp. 1–5. Discussion of main deficiencies in storage of fuel, and in the generation, distribution and utilization of steam. Address delivered at the Thermotechnical Convention in Münich.

Shanghai. Electrical Development in Shanghai, I. V. Robinson. Beama, vol. 8, no. 1, Jan. 1921, pp. 30–35, 3 figs. Steam-electric plant of 28,368 kw. capacity.

STEAM POWER PLANTS

Costs. Effect of Load Factor on Steam-Station Costs, Peter Junkersfeld. Mech. Eng., vol. 43, no. 2, Feb. 1921, pp. 108–110, 4 figs. Financial loss will result whenever it becomes necessary to operate power station at substantially higher or lower annual load factor than that for which station was properly designed. Load factor should be carefully considered in locating central station as well as in selection of equipment. Curves are given to show relative generating costs and boiler rating as affected by load factor, typical week-day load curves and load factors, and load factor as it occurs from day to day and month to month.

Steel Works. Modern Steam Generating Station, G. C. Emmons. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 65–78, 16 figs. Detailed account of performance of steel generating station of Republic Iron & Steel Co., Youngstown, Ohio.

STEAM TURBINES

Design. A New Graphic Method for the Calculation of Steam Turbines (Om Turbomaskiner), Matts Bäckström. Teknisk Tidskrift (Mekanik), vol. 50, no. 11, Nov. 10, 1920, pp. 149–166, 22 figs. 3 on 3 supp. plates. Author discusses basic formulas and principles for the calculation of turbines and explains diagram developed by him and called the temperature-drop diagram, by use of which it is possible to make calculations in a purely mechanical and simple manner.

Developments. Development of the Steam Turbine, Robert June. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 61–64, 2 figs. Development has taken place not only with respect to design of turbines, but in particular with respect to very great increase in their application to different services.

Specifications. British Standard Specification for Steam Turbines for Electrical Plant. British Eng. Standards Assn., no. 132, Oct. 1920, 8 pp. 3 figs. Technical provisions for supply of machines. Method of measuring temperature of steam.

Bars, Weight of. Weight Table for Estimating, F. W. Salmon. Am. Mach., vol. 54, no. 5, Feb. 3, 1921, pp. 182–183, 1 fig. Table giving weight of round steel bars per linear inch.

Basic Open-Hearth. The Basic Open Hearth Melting Shop Equipment and Practice in England, George A. V. Russell. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 31 and 38–45, 4 figs. Review of mixer plant and practice, melting furnaces, metallurgical practice, handling of materials and products and layout of plant. (To be concluded.)

Bibliography. Review of Iron and Steel Literature, 1920, E. H. M'Clelland. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 8–10. Also in Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 6–8. List of important publications during 1920, with a few of earlier date compiled by librarian of Carnegie Library of Pittsburgh.

Bluing and Browning. Bluing and Browning Steel Articles, Sidney Cornell. Chem. & Metallurgical Eng., vol. 24, no 7, Feb. 16, 1921, pp. 301–303. Commercial methods of producing oxidized finish on polished steel objects, including analyses of several browning solutions in use in various establishments

Gases in. Gases Obtained in Molten Steel—I, Henry D. Hibbard. Blast Furnace & Steel Plant, vol. 9, no. 1, Jan. 1921, pp. 51–53. Classification of gases and how to deal with them in order to make product sound. (To be continued.)

High-Speed. See STEEL, HIGH-SPEED.

Ingot Production. A Proposed New Ingot Mold of Steel, Robert C. Woodward. Iron Age, vol. 107, no. 4, Jan. 27, 1921, pp. 262–263, 2 figs. Cracks in ingots and their causes. Effect of heavy molds. Advantages of thin walls cooled by water.

Macrostructure. Use of Ammonium Persulphate for Revealing the Macrostructure of Iron and Steel, Henry S. Rawdon. Dept. of Commerce, Sci. Papers of Bur. of Standards, no. 402, Nov. 12, 1920, pp. 715–723, 7 figs. Method of etching.

Magnetic Reluctivity. Magnetic Reluctivity Relationship as Related to Certain Structures of a Eutectoid-Carbon Steel, C. Nusbaum, W. L. Cheney and H. Scott. Dept. of Commerce, Sci. Papers, Bur. of Standards, no. 404, Nov. 26, 1920, pp. 739–757, 7 figs. Changes in physical properties resulting from thermal treatment were studied for one per cent carbon steel and it was found that very rapid rise of maximum and residual induction and even more pronounced decrease in coercive force occur between drawing temperatures of 150 and 250 deg. cent. Such changes very likely mark transformation from martensite to troostite.

Manganese. See MANGANESE STEEL.

Metallography. Metallographic Methods for Determining the Nature of Non-Metallic Inclusions in Steel and Cast Iron (Methodes métallographiques pour déterminer la nature des inclusions non métalliques contenues dans l'acier, le fer et la fonte), M. M. Matveieff. Revue de Métallurgie, vol. 17, no. 11, Nov. 1920, pp. 736–752, 25 figs. Comparative value of different etching reagents.

Microstructure. Notes on the Microstructure of Annealed Soft Steel, with Special Reference to Phosphorus in Tin Plate, Geo. F. Comstock. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 60–63, 16 figs. Interpretation of photomicrograph.

Nickel-Chrome. See NICKEL-CHROME STEEL.

Phosphorus and Sulphur. Effect of Phosphorus and Sulphur on Steel, E. W. Rettew and L. A. Lanning. Trans. Am. Soc. for Steel Treating, vol. 1, no. 4, Jan. 1921, pp. 247–249. Phosphorus increases tensile strength without decreasing ductility and increases hardness without lowering electric conductivity. Sulphur increases susceptibility to corrosion.

Tool. High Carbon Open-Hearth Steel Versus Crucible Tool Steel in the Manufacture of Miscellaneous Tools, George Porteous. Trans. Am. Soc. for Steel Treating, vol. 1, no. 4, Jan. 1921, pp. 238–244, 5 figs. Open-hearth high-carbon steel with proper heat treatment gives as good results as are given by higher grade and more expensive tool steel.

Uranium. See ALLOY STEELS, Uranium Steel.

Wrought Iron vs. Single Refined Wrought Iron Versus Steel, V. E. Hillman. Forging & Heat Treating, vol. 7, no. 1, Jan. 1921, pp. 63–65, 8 figs. Argument in favor of feasibility of substituting soft basic open-hearth steel for single-refined wrought iron.

STEEL CASTINGS

Annealing. Annealing Steel Castings with Fuel Oil, R. R. Hillman. Iron Age, vol. 107, no. 4, Jan. 27, 1921, pp. 247–249, 1 fig. Design and operation of new furnace in plant of Atlas Steel Casting Co. Blast for combustion heated by outgoing gases.

Converter Process of Production. The Small Converter Process and Its Importance in the Production of Steel Casting (Die Kleinbessemerei und ihre Bedeutung für die Stahlgusserzeugung), R. Schmidt. Zeit. für die gesamte Giessereipraxis, vol. 41, nos. 51 and 52, Dec. 18 and 25, 1920, pp. 661–662 and 677–678, and vol. 42, nos. 2 and 3, Jan. 8 and 15, 1921, pp. 17–18 and 35–36. Writer relates his experiences with process in his capacity as inspection engineer for artillery workshops.

Electric Melting. Electricity Shop's Sole Heat Source, H. E. Diller. Foundry, vol. 49, no. 3, Feb. 1, 1921, pp. 87–91, 8 figs. Equipment installed at foundry of Emery Steel Castings Co., Baltimore, which specializes in light castings of intricate design.

Molding Sand for. Sand Plays Part in Poor Castings, R. J. Doty. Foundry, vol. 49, no. 3, Feb. 1, 1921, pp. 95–97. Clean, smooth steel castings are dependent upon facing and heap sand used. Close heap sand causes blows. Ten parts heap sand mixed with one part new sand in facing. Paper read before Am. Foundrymen's Assn.

Specifications. Meet Steel Castings Specifications, E. R. Young. Foundry, vol. 49, no. 4, Feb. 15, 1921, pp. 152–153. Work done under U. S. Ordinance Departments specifications. Table showing effect of various amounts of titanium on physical properties. Paper read before Am. Foundrymen's Assn.

MECHANICAL ENGINEERING

Volume 43 May, 1921 Number 5

An Investigation of Oxy-Acetylene Welding and Cutting Blowpipes

By R. S. JOHNSTON,[1] WASHINGTON, D. C.

This paper reports the results of and conclusions from an elaborate series of tests carried out by the Bureau of Standards, Washington, D. C., for the War Department on commercial apparatus for cutting and welding by the oxy-acetylene process, submitted by manufacturers for the purpose of the tests.

The welding tests were performed upon $^1/_2$-in. and $^3/_4$-in. steel plates and the cutting tests upon $^1/_2$-in., 2-in., 6-in. and 10-in. material.

The general conclusions from the tests were that there was a great deal of difference between the characteristics of different designs of cutting blowpipes, and that there was no make of apparatus which was equally proficient and economical for all the thicknesses of metal. Further, one of the prime essentials of a good welding blowpipe is its so-called gas ratio, which should be unity. Not any of the blowpipes tested proved capable of maintaining a gas ratio of unity during welding, although, as the author states, the welds were probably made with greater care than has ever been bestowed upon any like work.

The important problem of "flashback" receives extensive consideration, and the author concludes that a blowpipe designed to be absolutely free from flashback caused by any form of obstruction, under all working conditions, will also be the eminently safe blowpipe and the one which with ordinary care will produce sound welds. Such a blowpipe will be one so designed that, under all conditions of operation even to complete blocking of the gas exit at the tip end, there will be maintained a one-to-one volume delivery of each gas, at identical pressures.

In addition to the particulars regarding welding tests here presented, the complete paper gives full details of the series of cutting tests.

In the war the increased use by the American Expeditionary Forces of oxy-acetylene welding and cutting equipment necessitated large purchases by the Government. In discussions concerning the relative merits of procurable apparatus it became evident that no authentic data were available as to the relative merits of the various blowpipes. The Bureau of Standards was therefore requested by the Chief of Ordnance to make a test for the determination of "efficiency, safety and workmanship entering into the several makes of apparatus" (oxy-acetylene).

Of necessity, the emergency of the investigation limited its proposed scope. The manufacturers of welding and cutting blowpipes were invited to conference and were circularized in regard to methods of test. From a study of the results of these conferences and correspondence a tentative scheme of tests was developed. A series of preliminary tests was started, and from the results a set of tests and a method of conducting them were decided upon. Further study made it desirable that a more extended investigation of the oxy-acetylene blowpipe be made. The signing of the armistice relieved the urgency and a much more complete series of tests was proposed. The results of these tests are included in this paper.

In deciding on the final tests S. W. Miller, Mem.Am.Soc.M.E., was engaged as consulting engineer. After securing his suggestions the tests were submitted to the War Department for final suggestions before being submitted to the manufacturers of the apparatus to be tested.

Several weeks of preliminary work were given over to acquainting the expert welders and cutters from the Naval Gun Factory, Washington, D.C., and the New York Navy Yard with their new duties. The knowledge that the tests were to be started, together with the fact that most of the apparatus had been held for test for at least a year, brought forth requests from the manufacturers for the privilege of submitting new and improved apparatus, which were granted.

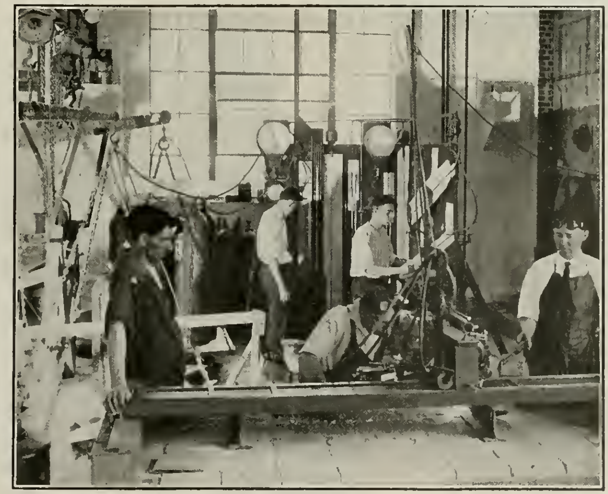

Fig. 1 Entire Testing Equipment

A copy of the tests to which it was proposed to submit blowpipes, accompanied by a circular letter giving the sizes and chemical analyses of the materials to be cut and welded, was forwarded to each manufacturer for him to furnish certain information. Each concern was later also individually notified of the day upon which its apparatus was scheduled to be tested.

The tests occupied about three months.

Acknowledgment

In the development of this investigation the general experience of a number of people was drawn upon that the question might be viewed from its broadest aspects, and its successful completion was largely due to the splendid coöperation received. Appreciation for such assistance is expressed to Col. L. B. Moody, Ordnance, War Department; Lt. Col. Warren R. Roberts, Q. M. C., War Department; Maj. A. B. Quinton, Jr., Ordnance, War Department; Maj. R. F. Carr, U. S. A., War Department; Maj. W. L. Simpson, Ordnance, War Department; Capt. A. L. Willard, Naval Gun Factory, Washington, D.C.; Capt. C. H. Rock, Hull Division, New York Navy Yard; and to the officers of the divisions of the

Abstract of a paper to be presented at the Spring Meeting, Chicago, Ill., May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper may be had on application. All papers are subject to revision.

Published by permission of Dr. S. W. Stratton, Director Bureau of Standards.

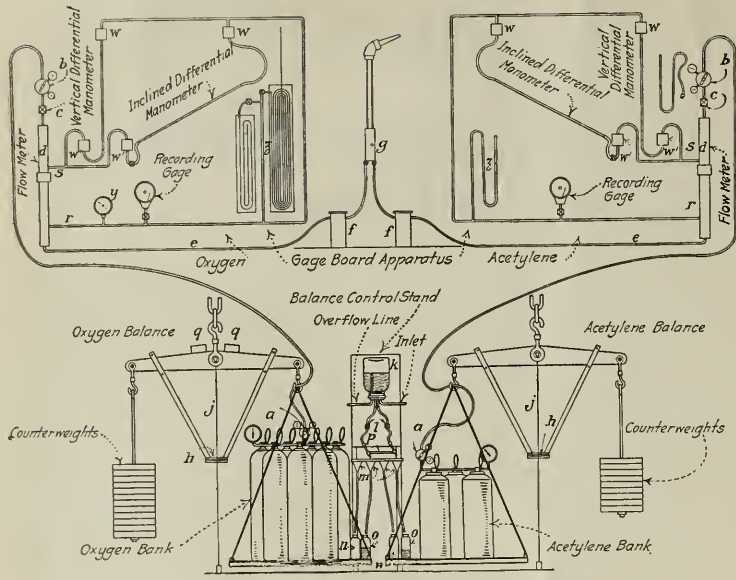

Fig. 2 Diagram of Entire Testing Equipment

Bureau of Standards and the several manufacturers of oxy-acetylene equipment.

The paper presented herewith is the result of a special investigation conducted at the Bureau of Standards for the War Department as represented by Major A. B. Quinton, Jr., Tank, Tractor and Trailer Division, Ordnance Department, through which Department the results of the investigation have been made available for public distribution.

Summary of Results

The results of this investigation would seem to warrant the following statements:

For the Cutting Blowpipes:

a That there is today no generally accepted theory for proportioning, for the cutting of metal of various thicknesses, the volume and velocity of the issuing cutting jet, with the result that none of the apparatus submitted to test proved economical for all thicknesses.

b That there is for any thickness of metal cut a limiting velocity of exit of the cutting jet at which complete utilization of the oxygen takes place, and a limiting value for the amount of oxygen required to produce a cut.

c That an increase in acetylene consumption, or oxygen consumption, or of the velocity of exit of the cutting jet beyond the limiting values, does not produce increased efficiency in commensurate ratio.

d That a large majority of the blowpipes tested were equipped with excessive preheating flames for the thickness of metal the tip is specified for, and that such excessive-sized flames are disadvantageous both from the standpoint of economy of operation and quality of work performed.

e That considerable improvement in economy of operation seems possible in cutting material of 2 in. thickness and that possibly this condition may be found to exist for metal of other thicknesses than those used in the tests.

f That the maximum thickness of metal that may be economically cut with an oxy-acetylene blowpipe of standard design when neither the material nor the oxygen is preheated and the cutting is done only from one direction, is about 12 in.

g That the cutting blowpipes due to their incorrect design are subject to the same "flashback" troubles found in the welding blowpipes.

For the Welding Blowpipes:

a That the blowpipes most subject to the so-called phenomena of flashback are those in which the oxygen is delivered at a pressure in excess of that at which the acetylene is delivered.

b That all the blowpipes tested, including those in which the acetylene is delivered at an excess pressure as well as the so-called equal- or balance-pressure blowpipes, are subject to flashback phenomena on account of inherent defects in their design.

c That the cause of the development of the conditions producing flashback is the setting up within the blowpipe tip and head of a back pressure which retards or chokes off the flow of one of the gases.

d That this back pressure is the result of confining or restricting the volume flow of the issuing gases at the tip end.

e That any cause tending to restrict the flow of the gases sets up a back pressure which immediately causes a change in the amount of each gas delivered to the mixing chamber.

f That a fluctuating gas-volume ratio, due to the restriction of volume flow, from whatever cause, prevents a blowpipe from maintaining constantly and at all times during operation the desired "neutral flame."

g That a blowpipe that cannot maintain under all operating conditions a neutral flame cannot logically be expected to produce sound welds.

h That all the blowpipes tested during this investigation either through improper gas pressures or improper interior design or both are incapable of maintaining a neutral flame (constant-

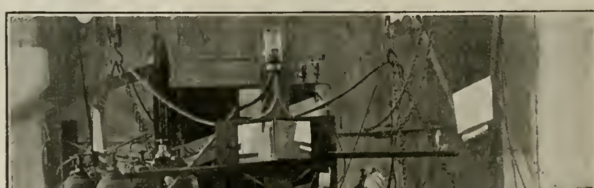

Fig. 3 Operator's Table and Balances

volume gas ratio) under all conditions of restricted gas flow and are therefore incapable of producing sound welds where there is any liability of the gaseous products of combustion being momentarily confined such as occurs in practically all welding operations.

i That the ability of a blowpipe to consume an equal volume ratio of gases when burning freely and undisturbed in air is no criterion that it is capable of producing sound welds, i.e., that it is

not subject to detrimental fluctuations in gas ratio during a welding operation and therefore is capable of maintaining a neutral flame under all operating conditions.

j That whether a blowpipe of present designs will consume an equal volume ratio of gases when burning freely and undisturbed in air depends on how nearly correct the operator sets the so-called "neutral flame," and experience indicates that the average operator checks the acetylene gas flow too much and actually develops an oxidizing rather than a neutral flame.

k That the question of the possible limiting strength and ductility or the efficiency of welds made by the oxy-acetylene welding blowpipe must await the development of a more satisfactory instrument, and that having such an instrument there is no reason to believe that a weld of clean, sound metal cannot be made with assurance during any welding operation and that such welds will or can be made to possess the proper physical properties.

Description of Equipment Used

In general the equipment used for making the tests may be listed as:

a Weighing system for determining amount of gases used during tests by loss of tank weight

b Gage-board system containing necessary pressure gages, regulators and orifice flowmeters

c Welding table

d Cutting table

e Flashback and safety testing apparatus.

Figs. 1 and 2 show the entire equipment. The tanked gases are "banked" and counterpoised on an equal-arm balance. The gas from these tanks passes through a regulator *a*, thence through a flexible hose to the back of the gage board. Passing through

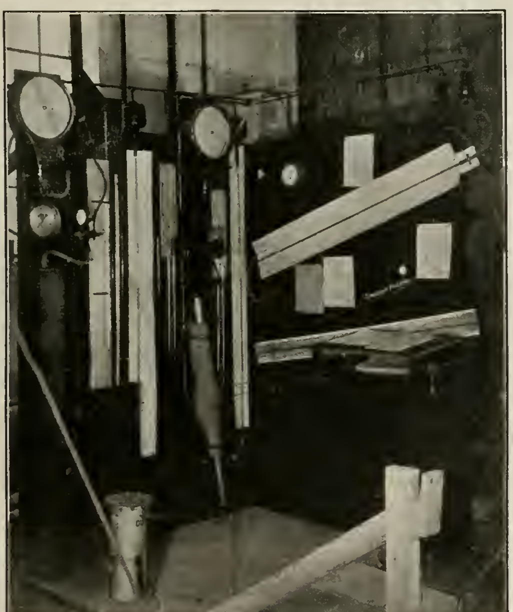

Fig. 4 Gage-Board System

the board the supply line enters a second regulator *b*, thence through a needle valve *c*, to the top of and through an orifice flowmeter *d*. The gas coming from the extreme bottom of the flowmeter is then conducted through a standardized length of flexible hose *e*, containing a safety flashback tank *f*, to the blowpipe to be tested.

Fig. 3 is a view of the operator's table, showing the use of mirrors for taking practically simultaneous readings of the balances.

Fig. 5 Welding Table

Fig. 4 shows the gage-board system. In the center of the board is one of the flowmeters, surrounded by wool-felt insulation.

Accuracy of Tests

Unusual precautions were taken to insure accuracy. If the gas losses through leakage exceeded 0.01 to 0.02 lb. per hour, actual testing of the blowpipes was not continued until the leaks causing such losses were located and stopped.

The values obtained for gas consumption were accurate to 0.005 lb., and in most cases probably much closer.

With the precautions taken with the regulators, it was readily possible to maintain under almost all conditions a pressure varying not more than 0.01 or 0.02 lb. from the desired amount. Autographic records gave visual evidence of the absolute uniformity of the pressure under which the blowpipes were operated during the tests.

Special orifice flowmeters were designed to facilitate securing data on continuous blowpipe action and as a check on the weighing system.

To complete the records the gage board was equipped with a standard calibrated thermometer, a psychrometer, a barometer and a stop watch.

Elaborate precautions were taken to maintain the gas conditions constant during the tests.

The Welding Table

All welding during the tests was performed upon the welding table illustrated in Fig. 5. This was a wooden-frame table approximately three feet square, the top of which was composed of firebricks. On top of the firebricks was placed a heavy casting channeled for a width of about six inches throughout its length. This formed the base upon which all the plates for welding rested during the welding operation. The plates were aligned centrally along this base with the idea that the casting with its grooved surface would permit of better heat radiation along the line of the weld and at the same time form a baseplate or background to prevent possible inconveniences from the blowholes caused by blowing the welded material through the bottom of the V of the test weld plates.

As indicated in Fig. 5, the line of the weld was placed directly in front of the welder and the welding was performed from the back toward the operator, thus giving him a full view of the work as it progressed. The welded plates were cut so that the welds were 1 ft. in length. Where 2 ft. of weld were made continuously, pairs of plates were set in front of each other with a slight space between the individual pairs and with proper allowance for expansion so that the process could be carried from one plate to the other without any interruption. The groove along the baseplate facilitated the preheating of the second pair of plates, so that the start upon the second weld was made under practically the identical conditions which existed when the first pair of plates was finished, a condition that would be equivalent to that which would occur if the weld was made as one of 2 ft. length instead of two of 1 ft.

The Flashback and Safety Apparatus

Flashback-Protection Tanks. The testing equipment also included in the gas lines two flashback tanks (f, Fig. 2, and Fig. 1). These tanks were essentially hydraulically controlled valves which

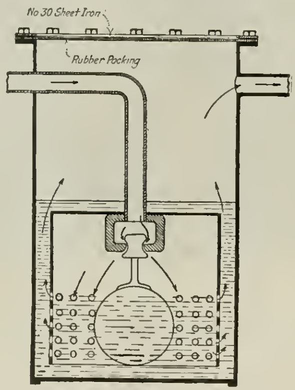

Fig. 6 Flashback-Protection Tank

were intended to prevent the propagation of an explosion in the blowpipe or gas line backward toward the gas supply. They are shown in sectional view in Fig. 6. While it was generally realized that the installation of the water seal of these flashback-protection tanks might be considered detrimental, due to the absorption of moisture by the gas, it became evident that their installation was nevertheless a prime necessity as a means of protecting the rather expensive gage-board equipment. It was believed further that, inasmuch as the oxygen in use generally came from cylinders that contained more or less water, the passing of the gas through the hydraulic seal of the flashback-protection tank would in reality tend to standardize the moisture content in the gas and therefore produce similar effects for all blowpipes.

These flashback-protection tanks proved extremely satisfactory for the purpose intended in that in several explosions they prevented the propagation of the flame beyond the flash tank. They generally ruptured by the blowing off of the head of the tank during the explosion. As furnished the heads were of rather thick sheet metal, fastened on with bolts as indicated on Fig. 6. This construction proved to be somewhat dangerous to the operators making the tests and the tanks were therefore modified in their construction as indicated in the figure by having a rubber packing and a thin sheet of metal fastened to the top with a heavy annulus. By this construction it was expected that if an explosion developed within the flash tank the thin metal sheet would rupture by tearing and thus minimize danger from flying parts.

Materials Used in Tests

Welding Rod. The welding rod used throughout the entire series of tests was secured from the Naval Gun Factory, Navy Yard, Washington, D. C. This rod was purchased in July 1917 under Navy Department Specification 22-W-4. A number of chemical analyses were made and the percentage composition was found to be as follows:

Carbon..........	0.024 to 0.03	Silicon.........	0.002 to 0.004
Manganese.......	0.05 to 0.08	Chromium.....	Trace
Phosphorus.......	0.01 to 0.015	Nickel........	Not detected qualitatively
Sulphur..........	0.023 to 0.024	Vanadium....	Not detected qualitatively

Steel Plates for Welding and Cutting. The steel plates used for welding were $^1/_2$ in. and $^3/_4$ in. in thickness. The material used for cutting was $^1/_2$, 2, 6 and 10 in. in thickness. All the material used in both welding and cutting except the 10-in. was furnished through the Engineer Corps, War Department, and was selected with special reference to uniform quality for any particular thickness. The $^1/_2$-in. material was furnished in plates 3 ft. by 5 ft. in size and was used for both welding and cutting tests. The middle section of each plate was retained as a sample for determining the qualities of the plate. The remaining pieces were used for making welds. During the welding tests it was the practice to use plates that were adjacent to each other in the main or full plate before it was cut into weld specimens, so that as nearly as possible the material used for any particular test would be identical.

The $^3/_4$-in. material for welds was received in plates 12 in. wide by 6 ft. in length. These plates were cut up into sections 9 in. in length, and for the full width of the plate, that is 12 in. All specimens for welding tests were finished with a butt joint of the single V 90-deg. included-angle type.

For the cutting tests the 3-ft. by 5-ft. by $^1/_2$-in. plates were cut into strips approximately $1^1/_2$ to 2 in. in width. The 2-in. material for cutting was furnished in sections 2 in. by 6 in. by 20 ft. These were cut, for convenience in handling, into 5-ft. lengths and in test operations cut lengthwise into sections 2 in. in width. The 6-in. material was shell billet steel furnished in 3-ft. lengths and was cut lengthwise in test operations.

Chemical analyses of a part of these materials indicated that they were of approximately the following percentage compositions:

$^1/_2$-in. Mild-Steel Plate for Welding and Cutting Tests:		*$^3/_4$-in. Plate for Welding Tests:*	
Carbon........	0.14	Carbon........	0.25 to 0.27
Manganese.....	0.32 to 0.36	Manganese.....	0.41 to 0.48
Phosphorus.....	0 012 to 0.013	Phosphorus....	0.011 to 0 013
Sulphur........	0.033 to 0.055	Sulphur........	0.041
Silicon.........	0.006 to 0.012	Silicon.........	0.004

Description of the Tests

The tests were started with the idea of submitting each manufacturer's equipment to the series of tests listed in a circular sent out under date of February 18, 1920. It was found, however, that the proposed series of tests was excessive from the time standpoint. One of the most serious drawbacks as a time-consuming element was the fact that a very large percentage of the blowpipes submitted for test would not operate with the pressures specified by the manufacturers. This condition was probably due to the fact that it is quite a customary practice to recommend setting the regulator pressures three to five pounds higher than the specified blowpipe pressures. By throttling the gases at the blowpipe-handle valves the operator insures having sufficient pressure available at all times to maintain the required velocity of exit of the gases at the tip end. He is therefore enabled to compensate for pressure fluctuations due to irregular action of the regulator, thus tending to minimize the development of flashbacks. The specifications for the tests distinctly stated that at least one of the blowpipe-handle valves must be maintained at full opening during a test. It was only by such a procedure that the gas consumption of a blowpipe could be definitely ascertained. For a great many of the blowpipes the pressures were too high to enable the maintenance of a stable flame with one of the handle valves at full opening.

Another quite serious source of trouble from the standpoint of time consumption was that due to leakage necessitating the dismantling and repacking of valves.

In order, therefore, that the entire investigation might not require an undue length of time it was decided that attention should be devoted only to the so-called primary tests, consisting of the welding, cutting, gas-ratio, and flashback tests. Such proposed tests as the variation of pressure within the blowpipe head, etc.,

[2] Values in parentheses are computed from flowmeter data.

were therefore abandoned. On the basis of the foregoing the following schedule of tests was adopted and all blowpipes tested during this investigation were submitted to them.

Welding Tests. All blowpipes reported upon were submitted to five welding tests, designated respectively as Tests 1*a*, 1*b*, 1*c*, 1*d*, and 2. All the tests numbered 1 were made with $^1/_2$-in. plate. Test 2 was a weld with $^3/_4$-in. plate.

Tests 1*a* and 1*b* were made with the tip sizes and pressures specified by the manufacturer when this was possible. For both of these tests a 2-ft. length of weld was made. These tests were identical in all respects with the exception that an attempt was made to evaluate the personal equation by using different operators. For Tests 1*c* and 1*d* a 12-in. length of weld was made. Both of these welds were made by the operator who made the weld of Test 1*a*, the idea being to maintain as nearly constant a personal equation for this series of tests as possible. Test 1*c* was run with the same size tip as 1*a*, but with pressures (both oxygen and acetylene) 50 per cent in excess of the pressures used for Test 1*a*. Test 1*d* was carried out similarly to 1*c* except that the pressures were 25 per cent below those used in Test 1*a*.

As mentioned above, the pressures specified by the manufacturer very often gave an exit velocity to the gas too high to permit of maintaining a stable flame at the blowpipe tip. In such cases the manufacturer's representative was requested to furnish a modified pressure that would enable the maintenance of a stable welding flame. Very often the modified pressure thus determined upon would not permit of the application of Test 1*c*, that is, a test with a 50 per cent increase in pressure in both gas lines. It was customary, therefore, in such cases to modify the test procedure and incorporate as a test in place of Test 1*c*, Test 1*e*, which was run under identical conditions with the above test with the exception that the pressure on both gas lines was reduced to 50 per cent of the pressure used to make Test 1*a*.

Tests 1*c*, 1*d*, and 1*e* were incorporated to show the effects of increased or decreased pressures on the operation and economy of the blowpipe. Such excess or decreased pressures are found to be quite common in many welding operations, due to carelessness on the part of the operator in setting regulator pressures or to imperfect regulator action. It was felt that a properly designed blowpipe should be capable of adjustment over a considerable range for any specified tip size. It was hoped in the investigation to secure data that would either verify this assumption or prove that it was absolutely essential to maintain exact pressures for satisfactory blowpipe operation.

Test 2 was a 12-in. length of weld of $^3/_4$-in. mild-steel plate. This weld was made in all cases by the operator who made the weld of Test 1*b*. This test was selected as indicating the probable results to be obtained with a blowpipe in heavy welding, and with Test 1 it was felt that it would give a fair idea of the adaptability of the blowpipe for welding purposes. The tips for welding $^1/_2$-in. and $^3/_4$-in. plate were selected as being the tips used respectively for the average-size weld and for the maximum-size weld, and therefore the best general average for determining the blowpipe's efficiency and safety.

[5] Weld made at normal pressure instead of at + 50 per cent pressure.
[6] Welds referred to in [5] and [6] are not included in the general average.

Gas-Ratio Tests. One of the prime essentials of a good welding blowpipe is its so-called gas ratio, that is, the ratio of the volume of oxygen to the volume of acetylene consumed. Theoretically a properly adjusted blowpipe requires equal volumes of both gases, giving the ratio of 1 : 1. In order to establish the ratios of the blowpipes under test each one reported upon was submitted to a series of gas-ratio tests, numbered *5a*1 and *5b*.

For these tests the blowpipe was allowed to burn freely in air with the same tip sizes and pressures as were used in the welding tests mentioned above. The blowpipe was supported upon a bracket stand with the tip in horizontal position. All gas-ratio tests were made upon the tips used for welding and no attempt was made to clean them before making the tests other than to blow them out with a rather high oxygen pressure. These tests might be expected to indicate the gas consumption of the blowpipe with the flame burning undisturbed from accidental obstructions, such as slag adhesions to the ends of the tips., etc., which occur in actual welding practice. The discussion of the welding blowpipe furnishes additional interesting information concerning the gas-ratio tests.

Flashback Tests. In order to determine the probable safety of operation of a welding blowpipe and, further, to secure information concerning the permanency of construction of the tip and blowpipe head, the blowpipes reported upon were submitted to two types of flashback tests.

One series of tests designated *3a* and *3b*, flashback tests on the tips used for welding 1/2-in. metal and 3/4-in. metal, respectively, consisted of the standard series of tests used by the Underwriters' Laboratories for determining the freedom from flashback and the safety of the welding blowpipe. Each of these tests consisted of four distinct operations. The first three of these operations were carried out as follows: After being properly adjusted to neutral flame the blowpipe was tested for flashback by drawing the tip at varying angles across the surface of, and finally pressing the tip end firmly against, certain materials. For this test a cold steel plate, a firebrick, and a piece of wood were used. Finally the tip was used to make a pool of molten metal in a cast-iron block, flux being used to assist in maintaining the fluid condition of the metal, and the tip suddenly plunged into the pool of metal.

Another series of tests intended to determine the permanency of construction and designated as the Severe Flashback Test, Test 4, was carried out by supporting the blowpipe on a vertical sliding carriage in such a manner that at the proper instant the ignited and carefully adjusted blowpipe could be lowered so that the end of the tip was directly over the center of a hole 2 in. in diameter and 2 in. deep, drilled in a heavy cast-iron block.

Discussion of Test Results

The Welding Blowpipe. It is universally accepted that outside of the mechanical features of design that affect weight, balance and convenience of operation, the prime essentials of a strictly satisfactory piece of apparatus are:

a Safety under all operating conditions

b Freedom from the so-called phenomena of "flashback" or sustained backfire

c The quality of maintaining under all operating conditions a welding flame that is neither oxidizing nor carbonizing, one technically known as a "neutral flame," which in the process of combustion consumes, as nearly as possible, equal volumes of oxygen and acetylene; that is, maintains as nearly as possible the theoretical gas-volume ratio of unity.

The tests of this investigation were decided upon with the idea of furnishing data that would enable blowpipes to be compared with respect to these essentials.

A study of the data obtained at the completion of the prescribed tests showed so many apparent inconsistencies that it was evident that there was a governing factor that was not understood, and that was, so far as test data were available, not in evidence. Irrespective of the fact that particular attention had been paid to insuring identical working conditions and gas-pressure control, and that especial care was taken to secure exceedingly competent and unbiased operators, the results obtained from the welding tests seemed extremely unsatisfactory. Gas ratios obtained during actual welding operations were extremely high. Those obtained when the blowpipe was burning freely in air were also higher than was to be expected. In tests for flashbacks there seemed to be a difference in the ease with which they could be developed in blowpipes of different manufacture, but there appeared to be no criterion that would enable one to say just why such phenomena could be caused more easily in some pieces of apparatus than in others, or why with some pieces of apparatus flashbacks could be produced at times quite readily and at other times with difficulty. Finally the general quality of the welds produced during test, although executed with the greatest care and shown by tensile tests to be of a higher strength than is generally secured in most welding shops, was far from satisfactory.

(*Continued on page 359*)

The Design of Large Locomotives

Features Which Keep an Engine in Service a Maximum Length of Time, Reduce Maintenance and Repair Costs, and Increase Revenue-Earning Power

By M. H. Haig,[1] Topeka, Kan.

After discussing various restrictions and limitations in the design and construction of large locomotives due to the inability of existing bridges and tracks to carry the necessary weight and because dimensions must be governed by clearances of bridges and structures, the author expresses the opinion that the physical conditions of a road should be adjusted to the requirements of the locomotive, and that the only controlling factors should be the size of train and the traffic of the territory.

Leading features of locomotive construction such as relative size of cylinders, total heating surface, grate area, principal dimensions, etc., have been treated at length by various writers. Features which have not been so discussed, however, are those which keep a locomotive in service a maximum length of time, reduce engine failures to a minimum, reduce cost of maintenance and repairs, and increase revenue-earning power. And it is in order to arouse interest in those details which are not always given the attention to which they are entitled, and in the quality of material entering into the construction of locomotive parts, that the author proceeds to their consideration. These, in the order of their treatment, are: Counterbalance, crossheads, driving wheels, crosshead pins, piston rods, cylinders, frame braces, boiler cracks, back flue sheet, grate rigging, water columns, cab equipment, and tender capacity. The author's opinions on these topics are presented in the hope that discussion will bring out the experience of others not only on these but on additional details of locomotive design and construction.

The design of a large locomotive depends on the service to which it is to be assigned. The service varies with the weight of the train to be hauled and the number of cars in the train, and is affected by the topography of territory on which it is to operate, ruling grades in each direction, length of grades, average speed between terminals, method of dispatching, whether single or double track between terminals, etc. This information being available, it is a reasonably simple matter to determine upon the leading features of a locomotive to meet the requirements.

Restrictions and Limitations Imposed

For a locomotive to give practically 100 per cent service, its design and construction must not be restricted by personal opinion or by physical limitations of the road. If the weight needed for adhesion in starting a given train is restricted by an opinion that certain wheel loads should not be exceeded or because bridges and track are not capable of carrying the necessary weight, then the capacity of the locomotive is restricted and the train must be adjusted to the locomotive, instead of the locomotive being built to suit the train. This in turn has a tendency to limit a division or a railroad as a whole. Limitations such as these, together with clearances of bridges and structures, obstructions along the right of way, etc., affect the locomotive design and construction. The locomotive as a whole is dwarfed, or some of its vital or essential parts are so dwarfed as to cripple the machine as a whole.

A railroad is a plant, establishment or organization for manufacturing transportation. The locomotive is a very important part of the plant and is one of the most direct earners of revenue from which the transportation-manufacturing plant obtains its income. As such, it is a matter of business and economical principle to adjust some of the physical conditions of the road to meet the requirements of the locomotive, to prevent dwarfing it and to prevent sacrificing its power. Meeting these requirements of the locomotive amounts to meeting the necessary requirements of traffic. No turntable installed at a principal roundhouse should be less than 100 ft. long, and in many cases the length should be 125 ft. The distance between the walls of a modern roundhouse should be great enough to permit closing the door behind the tender of a Santa Fe or Mikado type locomotive and have ample room for trucking between the locomotive pilot and the outer wall of the roundhouse. Passing tracks should be long enough to take trains justified by the business and traffic of the division or territory. Bridges, rail and roadbed should be capable of carrying a static wheel load of at least 65,000 lb. per pair and of permitting the additional stresses resulting from a freight speed of at least 45 miles per hour. In meeting the requirements of rail stresses particular attention should be given to the employment of heavy rails on curves.

Unless these physical conditions are provided, a locomotive cannot be designed and constructed without restriction and proper power cannot be furnished to meet requirements. The only governing factors should be the size of train and the traffic of the territory.

Leading Features of Locomotive Construction

Leading features of locomotive construction such as relative size of cylinders, length of stroke, total heating surface, superheating surface, grate area, etc., have been well covered by handbooks and pamphlets issued by locomotive builders and by reports to the various associations, as well as by articles in the technical press. Tables of principal dimensions of large locomotives are obtainable from the same sources, together with detailed descriptions of features of design and construction which have met with general favor and some which have been short-lived. A discussion or comment on these features would therefore be largely a repetition of facts already presented and easily available.

Features which have not been so generally discussed and exploited are those which keep a locomotive in service a maximum length of time, reduce engine failures to a minimum, reduce cost of maintenance and repairs, and increase revenue-earning power. Among these, durability of material and accessibility of parts are important factors. The latter implies arrangements by which a locomotive is made free from complicationsin construction, inexpensive to repair, easy to maintain, and so put together that needed repairs can be made handily and quickly.

Almost as important as providing a locomotive that will meet the requirements of trains to be hauled and traffic conditions, is providing one that requires minimum repairs—a locomotive that after one trip is ready to be turned for the next trip.

A locomotive is in revenue-earning service only when it is hauling trains. Any road can make a study and determine what proportion of its locomotives are unserviceable and what percentage of the time its serviceable locomotives are on the road. Such information will show what percentage of the time its engines are earning revenue.

To maintain the advantages of designs already existing and to develop these still further requires the unlimited coöperation not only of the mechanical, civil-engineering and operating forces of the railroads, but also of the locomotive builders, and particularly of the manufacturers of material.

The necessity for unlimited coöperation by manufacturers of material is evident from the study of failures of parts both large and small. On the principle of encouraging further consideration of such coöperation by all concerned and for the purpose of arousing interest in those details of locomotive construction which are not always given the attention to which they are entitled, a number of details which seldom appear among "leading dimensions" will be discussed.

Counterbalance

Important among such details and one which is affected particularly by designers and manufacturers of material, is the counterbalance. The blow from the counterbalance is caused by the differ-

[1] Mechanical Engineer, Atchison, Topeka and Santa Fe Railway Company.

Abstract of a paper to be presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper may be obtained upon application. All papers are subject to revision.

ence between the weight of the revolving parts carried by the pins and the total weight in the wheel to balance both the revolving and reciprocating weights. In other words, it is the weight in the wheel to balance reciprocating weight that causes the hammer blow.

Weight of reciprocating parts therefore affects hammer blow of driving wheels, riding qualities of locomotives, possible damage to track and bridges and total weight of locomotive. It is particularly essential to make these parts as light as possible, and to make them light the material must be durable.

Due to the increase in weight of locomotives and to the hammer blow on rails when reciprocating parts are heavy, the 1915 Committee of the American Railway Master Mechanics' Association made the following recommendation:

> Keep total weight of reciprocating parts on each side of locomotive below $^1/_{160}$ part of total weight of locomotive in working order and then balance $^1/_2$ weight of reciprocating parts.

An attempt to counterbalance large locomotives in both freight and passenger service according to this recommendation has demonstrated its merit, but has further demonstrated that the durability of both cast and forged steel must be improved if the method is to be continued.

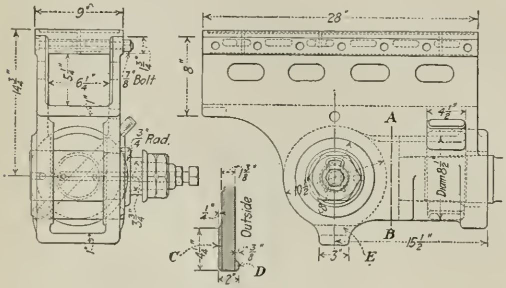

Fig. 1 Laird Crosshead Used on Various Types of Large Locomotives

Crossheads

The Laird type of crosshead is lighter than several other designs, its performance is very satisfactory in service, and it therefore has advantages in designing for light reciprocating parts. A crosshead of this type used interchangeably on large freight and passenger locomotives is shown in Fig. 1.

The construction originally employed is shown by the figure, with the exception of later reinforcement at *C*, *D* and *E*. After about a year's service these crossheads began to break, the weakness appearing in the relatively thin wall between the hub around the piston rod and the lighter hub around the crosshead pin. The same weakness developed in crossheads of similar general design among locomotives of three or four different classes. The defects which proved common to these different crossheads are shown in Fig. 2.

By breaking up these crossheads in order to investigate the nature of the metal, it was found that in most cases each fracture had its origin in a shrinkage crack. The metal in most of the broken crossheads was found to be porous and to contain blowholes or gas holes, or shrinkage cracks, cold shuts or pipes. In some cases all of these defects were present.

Fig. 2 shows very clearly the difference in cross-section of the metal at and near the break. This difference is no doubt largely responsible for the defects in the metal which have caused an epidemic of failures. Crossheads of this general design have been used for many years, and as it appears impossible to modify the shape to advantage, the question, then, is whether foundries can adjust their practices to cast such irregular sections without blowholes, shrinkage cracks and other defects. This is one of the opportunities for manufacturers of material to coöperate with the locomotive designer.

Driving Wheels

Another irregular section which causes shrinkage cracks is the cast-steel driving-wheel center. Rims and spokes are of much lighter section than the hub and counterbalance, and shrinkage cracks are not unusual at the juncture of these light and heavy sections. Foundries which cast locomotive parts have these conditions to meet and it is believed that foundry practices can be adjusted to meet them.

Crosshead Pins

In the development of locomotive construction within recent years the union link of outside valve gears has been connected direct to the crosshead pin. This reduces weight by eliminating the crosshead arm and by shortening the length of the combination lever, thus lessening reciprocating as well as total weight. A further advantage is in eliminating the bolted connection between the crosshead and arm.

In eliminating the crosshead arm the duty of the crosshead pin is increased. A broken crosshead pin is more serious than a broken crosshead arm. When a pin breaks there is a possibility of something else being broken and a very great probability of a cylinder head being knocked out and carrying a part of the cylinder wall with it. It is therefore absolutely necessary that the material in the crosshead pin shall be of a good quality, and the steel used should contain about 0.50 per cent carbon and have a tensile strength of 80,000 lb. per sq. in.

By reference to Fig. 1 it will be observed that the diameter of the union link shank of the crosshead pin is $3^3/_4$ in. This is believed to be considerably larger than usual in locomotive design. Even

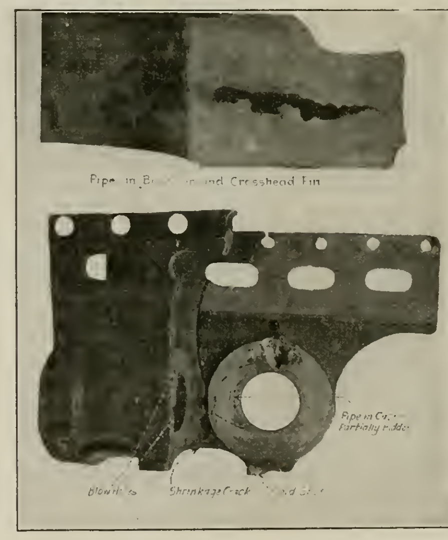

Fig. 2 Location and Nature of Defects in a Poorly Cast Crosshead

though the stresses in the crosshead pin are low, this large size appears to be a necessary precaution against the uncertainty in quality of material. As a further precaution there is a $^3/_4$-in fillet at the end of the shank.

Piston Rods

The greater number of breaks in piston rods of at least one railroad have been through the keyway. Next in order is the location in the crosshead fit adjacent to the collar. Breaks in the body are usually adjacent to the collar at the crosshead fit and occasionally at the collar adjacent to the piston-head fit.

The mechanical fit between the rod and the crosshead is often responsible for the breakage of the former. If there is not a good bearing throughout the length of the fit or at both ends of it, there is opportunity for a slight movement of the rod in the crosshead. This starts a crack which gradually progresses into a fracture. To facilitate making a good bearing at both ends of a piston-rod fit

greater than the keyway and about midway between ends of the fit. To prevent cracks starting in sharp corners at edges of the keyway, these edges are chamfered at both ends of the keyway and entirely around.

Rods with comparatively low stresses sometimes fail in such a manner that it is difficult to attribute a cause unless quality of material is responsible. This is true of rods of ordinary carbon steel as well as those of specially refined steel and of alloy steels. In this is another opportunity for the assistance and coöperation of manufacturers of material.

Cylinders

Failures of parts such as those described in preceding paragraphs, quality of material, uncertainty of cylinder cocks being operated, extreme variation in temperature due to use of superheated steam, foundry practices, etc., all affect the design of cylinders. Consideration of these and other features has resulted in the development of the design shown in Fig. 3, which is that of the cylinder of a Mikado locomotive. Except for modifications in dimensions this represents cylinders used also on Santa Fe, Mountain, Pacific and other locomotive types. The principal features of this cylinder are:

The steam and exhaust channels are free from obstructions and restrictions which will interfere with free flow of steam. The exhaust channels are gradually reduced in area from valve bushing to base of exhaust pipe in such a manner that the cross-sectional area of any point in the channel is not larger than any area through which exhaust steam has previously passed.

A weakness in castings of some large cylinders has been in the wall around the live-steam port. As shown in Fig. 3, this wall is made 2 in. thick and the distance across the port below the valve bushing is 24 in. To reduce stresses in this wall it has been made thicker than most other walls of the casting and, compared with former practice, width across port has been reduced about 4 in. The bridges in the live-steam port are 2 in. thick. They were formerly but 1 in. in thickness and it was not unusual to find them cracked clear through. The change was made to increase the cross-section of the bridges in relation to the adjacent walls and thereby reduce tendency to shrinkage cracks.

To obtain a good cylinder casting from any design, it is necessary to have proper coöperation of the pattern shop and the foundry. Patterns must be well built and carefully checked. The checker should exercise especial care to see that patternmakers apply all the fillets called for. The foundry should so arrange the mold

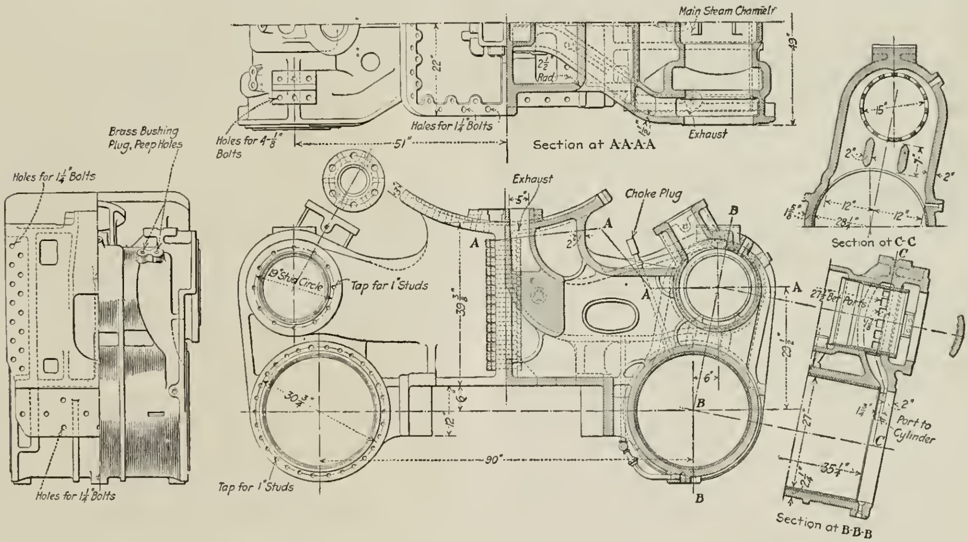

Fig. 3 Cylinder for Large Locomotive

- Simplicity in construction
- Uniform thickness of metal
- Absence of heavy metal sections at junctions of walls
- Walls and parts of ample thickness for strength, well ribbed, well braced and arranged with easy curves and generous fillets
- Uniform sectional area throughout length of steam and exhaust passages
- Short steam ports
- Small steam clearance
- Sections of metal, fillets and other features arranged to eliminate internal stresses set up in metal when cooling
- Double row of splice bolts holding halves of cylinder saddle together
- Double row of bolts at smoke arch
- Triple row of horizontal bolts securing cylinder casting to frame
- Depth of saddle casting directly above frame forming a box section and providing strength where shallow castings used with double-frame rail failed in the past
- Location of valve close to cylinder, permitting short ports, straight valve gear without offsets, and application of nearly straight steam pipe
- Large openings to cylinder cocks.

as to obtain uniform sections of metal. To insure this, careful measurements should be taken when cores are being set and a drop light should be let down into the mold when taking measurements.

Frame Braces

Locomotive frames are subjected to repeated lateral and twisting stresses, as well as to various other stresses, which will gradually break a single frame, but which can be withstood indefinitely by the application of substantial braces. An example of a pair of strong frames substantially braced is shown in Fig. 4, the arrangement illustrated being for a Santa Fe type locomotive. Bracing in the manner shown has been used for a number of years very successfully, and with very little modification is applicable to any locomotive class with outside valve gear.

Braces must be bolted to frames securely. Where braces or castings of other parts are bolted to a frame, the bolts should be applied with the head end bearing in these parts and not the thread end. This will provide for bearing on the bolt through the full thickness of the part bolted to the frame.

Boiler Cracks

In using the boiler to supplement the frames in forming a backbone or foundation from which to brace machinery parts, the boiler

shell is subjected to additional stresses which result in cracks in the sheets. The most frequent causes of these cracks are guide-yoke braces, valve-motion braces and the ordinary belly braces to frames. Guide-yoke and valve-motion braces are often very stiff and are bolted securely to the frames and studded to the boiler. When the boiler expands the braces and connections are held rigidly by the frame and there is a tendency for the boiler to tear itself loose from these fastenings. This sets up strains in the metal which are aggravated by the vibration and pounding to which braces are subjected.

In an effort to overcome these cracks, outside welt plates have been riveted to the boiler to reinforce it where the brace pads are studded on. Experiments have been made with flexible, or partially flexible, braces, some of which have so far been successful.

On engines where breakage of braces has occurred, some of them are being replaced by braces with a pin connection at the lower as well as upper end. Where the use of pins is not favored, however, a thin plate in connection with a cast-steel brace should provide sufficient flexibility for expansion of the boiler and proper stiffness for bracing machinery parts.

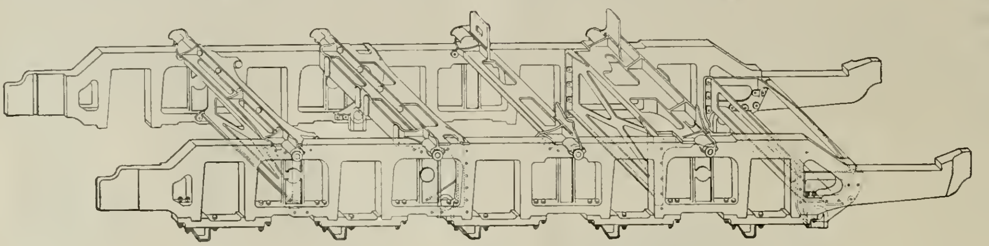

Fig. 4 Frames and Frame Bracing of a Large Locomotive

The Back Flue Sheet

Boiler back flue sheets of large locomotives are renewed and patched more frequently on account of cracks in the knuckle near the top flange than from any other cause. On at least one road the average life of flue-sheet knuckles is 3 years and 3 months, the maximum and minimum varying within rather a large range.

A minimum limit of distance of top flue holes from top of flue sheet that is considered practical is shown in Fig. 5. To omit flues near the top of the flue sheet sacrifices heating surface. To raise the top of the flue sheet above the usual location of flues increases the weight in the firebox, adds to the amount of water necessary to cover the crown sheet, and by requiring increase in diameter of boiler to maintain steam space above the crown sheet, increases the weight of the boiler and consequently the weight of the locomotive as a whole.

Considering the stresses and the peculiar punishment to which flue-sheet knuckles are subjected, it is important to specify this material carefully. The following limits have been demonstrated by experience as practical:

Tensile strength	52,000 to 60,000 lb. per sq. in.
Elongation	Not less than 25 per cent
Carbon	0.12 to 0.25 per cent
Sulphur	Not over 0.025 per cent

The Ashpan

Various details at the rear of a locomotive should be arranged to permit a large ashpan with smooth slope sheets at an angle that will permit cinders to fall to the hopper without obstruction, and its design should be decided on before the designs of surrounding parts have progressed too far. Equally as important is area between the ashpan and mud ring or through parts of the pan, to admit air to support combustion. This area should be at least equal to the area through the boiler flues, and preferably a little greater.

The Grate Rigging

The place for grate rods, which operate the grates, is near the center of the grates and above the deep portion of the ashpan. On locomotives without stokers this arrangement is not difficult to provide for. With some stokers, however, grate rods in this position are interfered with, and this has resulted in some grate rods being located along the sides of pans, in certain cases very close to the flat portion or shelf of the pan under the mud ring. In this position the rods collect cinders close to the air openings and obstruct the admission of air for combustion. With steam grate-shaker equipment and stoker the grate rods can be located near the center of grates by applying a set of intermediate rockers.

Water Columns

A very thorough investigation into conditions affecting the performance of water columns indicates that the most satisfactory serivce is obtained with a column and connections conforming with the following specifications:

Inside diameter of water column ..... $3^1/_2$ in.
Inside diameter of top steam pipe ..... 2 in.
Inside diameter of connection of column to top steam pipe ..... Not less than 2 in.
Inside diameter of bottom connection to boiler ..... $^3/_4$ in.
Top steam pipe as short as possible consistent with required location forward of boiler back head flange
Minimum number of bends in top steam pipe to column. This pipe to be lagged
No valves between water column and boiler either in top steam pipe or in bottom connection
Water-column bottom connection should extend into boiler far enough to clear nearby T-irons or other obstructions, approximately $4^1/_2$ in. from inside of sheet.

Cab Equipment

The back wall of the cab should be far enough away from the boiler back head to give room for a satisfactory seat, for the application of the required equipment, and for a man to pull the throttle open without striking his arm against it. A distance of 46 in. from the face of back head at the center of fire door to the back wall of cab will meet these requirements.

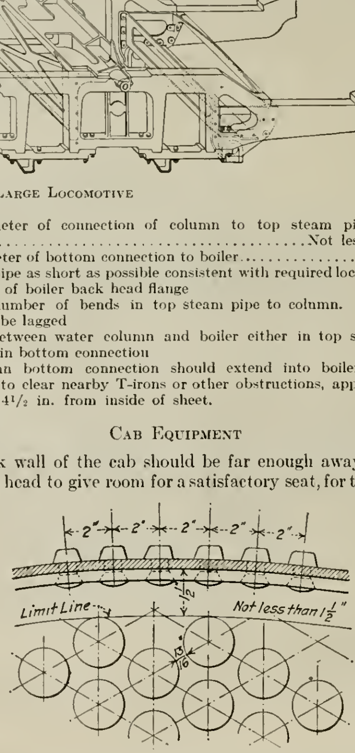

Fig. 5 Minimum Distance Between Top Row of Flues and Flange of Back Flue Sheet

Engineers' and firemen's seats should be located where the men can see ahead and their vision should not be obstructed by air pumps located too high, classification lamps misplaced, running boards too high at the front, or other obstructions that might interfere with their seeing semaphores, switch stands, etc.

Dry-Vacuum Pump Capacity Tests

Description of New Method Employing the Low-Pressure Nozzle for Air Measurements—Typical Volumetric-Efficiency Curves

By SNOWDEN B. REDFIELD,[1] EASTON, PA.

The method of testing moderate-vacuum pumps described in this paper has a number of advantages. The nozzle used discharges into a back pressure which is greater than the critical. This permits the determination of several values of volumetric efficiency over a range of vacua without changing the nozzle. The method of plotting of results described by the author is a graphic proof of the accuracy of the theory involved and permits ready estimation of approximate performance of a given pump.

CAPACITY tests of dry-vacuum pumps are not common and their actual volumetric efficiency at a given vacuum is usually a matter of conjecture. Furthermore the characteristic curve illustrating the law of the change of volumetric efficiency with vacuum is but little known. It is the purpose of this paper to describe a simple, practical and undoubtedly accurate method of testing dry-vacuum pumps by means of the low-pressure nozzle and to show the characteristic curves of one kind of pump as manufactured by the Ingersoll-Rand Company. The pump illustrated and tested is but one of many similar all-plate-valve pumps tested by the writer. It is not built for extremely high vacua, but is intended for that extensive class of service met with in many industrial and chemical processes calling for what is known as a "moderate vacuum."

Although it is not always appreciated, it is a fact that a dry-vacuum pump is only a compressor working through a range of pressures low down on the scale. Every compressor is really a "booster," that is, it takes in its air or gas at one pressure and compresses and delivers it at a higher pressure. The intake may be at any pressure below atmosphere, exactly at atmosphere, or even a hundred or more pounds above atmosphere. Similarly the discharge pressure may be anything, as long as it is above the intake pressure. In all cases the cycle of intake, compression and discharge is essentially similar, although the weight of material and the power required will vary widely according to the pressures.

Nozzle Tests for Air Measurement

Within the last ten years tests for capacity of air compressors by means of the low-pressure nozzle have become quite common, and the measurement of air has long since passed from the realm of assumption to that of practically standardized methods of determination with considerable accuracy. This being true of the air compressor, it at once becomes true for the dry-vacuum pump, as they have just been shown to be members of the same family, and by methods similar to those standardized for the air compressors we may obtain the exact amount of air handled by a dry-vacuum pump at any vacuum.

Before going further, a word should be said in explanation of the terms "low-pressure nozzle" and "high-pressure nozzle." These are the popular terms to designate whether the back pressure into which the nozzle is discharging is above the critical pressure or below it, respectively. The critical back pressure for air is 0.53 of the upstream, or initial, pressure, and if the back pressure is above the critical, the expansion ratio is relatively low, so the nozzle may be called "low-pressure." If, on the contrary, the back pressure is less than the critical, the total expansion ratio is relatively high, and the nozzle is said to be a "high-pressure" nozzle. The following table gives the class of nozzle for various pressure ratios, assuming a 30-in. barometer:

As explained in many books on thermodynamics, if the back pressure is below the critical, the expansion in the nozzle is only down to the critical pressure in the throat of the nozzle and the rest of the expansion takes place beyond the throat without increasing the quantity of discharge. This immediately fixes the constant quantity of air a nozzle of a given size will pass from a given upstream pressure into any and all back pressures below the critical. For testing compressors with discharge pressures above 13 lb. gage, the nozzle discharging to atmosphere, different quantities of air may be made to flow through a high-pressure nozzle of a given

TABLE 1 CLASSIFICATION OF NOZZLES FOR AIR MEASUREMENT

	Upstream Pressure		Back Pressure		Ratio of Back Pressure to Upstream Pressure	Kind of Nozzle
	Gage	Abs.	Gage	Abs.		
For Pressure Work.....	100	114.7	Atm.	14.7	0.128	High-pressure
	20	34.7	Atm.	14.7	0.424	High-pressure
	12	26.7	Atm.	14.7	0.551	Low-pressure
	2	16.7	Atm.	14.7	0.880	Low-pressure
For Vacuum Work.	Atm.	14.7	2″ vac.	13.75	0.933	Low-pressure
	Atm.	14.7	8″ vac.	10.80	0.733	Low-pressure
	Atm.	14.7	15″ vac.	7.36	0.500	High-pressure
	Atm.	14.7	26″ vac.	1.964	0.133	High-pressure
	Atm.	14.7	28″ vac.	0.982	0.066	High-pressure

size by changing the upstream pressure. This can be accomplished by maintaining the compressor discharge pressure constant in a receiver by means of a throttle which passes the air to the nozzle at some slightly lower pressure. The lower pressure beyond the throttle, at nozzle entrance, will adjust itself automatically to the quantity of air to be passed, so that considerable flexibility may be obtained for compressor testing with this class of nozzle.

Recently some capacity tests have been made upon vacuum pumps using a high-pressure nozzle. This is done by placing a nozzle in the wall of the vacuum vessel, drawing air from the atmosphere, and calculating the flow from well-known formulas. While this has been an assistance in some cases, it is not a flexible method and a different size of nozzle must be used for each vacuum at a given pump speed. This makes it a practical impossibility to test a vacuum pump at a specified vacuum, because one cannot tell just what size of nozzle will be required. With the "low-pressure" nozzle a given nozzle diameter may be used for a very considerable range of vacua and a capacity measurement may be made at any specific vacuum desired.

Due to the excessive noise of a "high-pressure" nozzle and the inaccuracies and difficulty of reading pressure gages of the spring type, the low-pressure nozzle with water-column pressure gage has been adopted by most of the leading compressor builders and is being incorporated into the new test codes of the Society now under revision.

Inspection of the table already given shows that as soon as the vacuum exceeds about 14 in. of mercury, a nozzle discharging from atmosphere into this vacuum is discharging into a pressure below the critical and we have at once a nozzle of the high-pressure class. We have already shown that a high-pressure nozzle of a given size discharging from a constant upstream pressure into a back pressure below the critical will pass only a constant air quantity, irrespective of how low the back pressure may become, and as in this case the upstream pressure remains atmospheric, the quantity of air passed will be constant for a given-sized nozzle for all vacua above 14 in. It then follows that the vacuum obtained with a given-sized nozzle of the high-pressure type, which passes a fixed quantity of air, can be changed only by changing the speed of the pump. If the pump speed is increased, the air must expand after it has passed the nozzle in order to fill the increased piston displacement, and this expansion must be accompanied by a reduction of pressure, which is the same thing as an increase in vacuum. Reduction of pump speed is accompanied by the reverse process and the vacuum will be decreased; but the fact remains that a high-pressure nozzle of a given size will pass only a constant quantity (weight) of air and will produce only one vacuum at a given pump

[1] Engineer in Charge Easton Engineering Dept., Ingersoll-Rand Company, Mem.Am.Soc.M.E.

Abstract of paper to be presented at the Spring Meeting, Chicago, Ill., May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper can be obtained on application. All papers are subject to revision.

speed. Furthermore, it is impossible to select a nozzle of this type to test a given pump at a specified vacuum.

Applying Low-Pressure Nozzle to Vacuum Pumps

As a more flexible and probably more accurate method of testing dry-vacuum pumps, the set-up shown in Fig. 1 lends itself well. In this figure the vacuum pump is drawing from tank A, and any desired vacuum may be produced in A and the pipe connecting it to the pump by adjusting throttle B. Throttle B is a globe valve provided with a long handle for close adjustment. Its stuffing-box gland is liberally daubed with heavy oil to insure against leakage. The running vacuum is observed on mercury column E, and, as said, this vacuum may be adjusted by B to anything desired. Tank C has in its end the nozzle D, taking air from atmosphere, and the pressure drop through D is shown by the water column F. A thermometer G shows the temperature of intake to vacuum-pump cylinder and thermometer H shows the temperature of the air entering the nozzle.

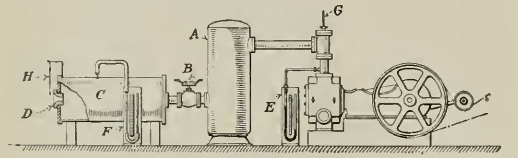

Fig. 1 Apparatus for Low-Pressure Nozzle Test of Vacuum Pump

We now see that the apparatus is composed of three parts: the pump to be tested; tank A and piping in which any desired vacuum is to be maintained, measured by mercury column E and thermometer G; and tank C, which by means of nozzle D, water column F, and thermometer H measures the amount of air handled. As B is adjusted, the quantity of air handled will change. This will change the vacuum as shown on gage E, and water column F will also change to measure the new quantity of air passing through nozzle D. As the drop through D is small, the pressure in C is well above the critical at all times and the quantity of air passed will change with the slight vacuum in C, as measured by water column F. Thus there is a wide range of air quantities which can be made to pass through a low-pressure nozzle of a given size, and by proper adjustment of throttle B any number of test points may be obtained as close together or as far apart as desired, independent of the speed of the pump. Furthermore, any specified vacuum may be secured at will, up to the limit of the machine.

Formulas for Calculating Flow Quantities

For calculating the flow of a gas through an orifice or nozzle, the best-known formula for the case where the back pressure exceeds the critical is that which equates the energy on the two sides of the nozzle and assumes adiabatic expansion in the nozzle. This formula is given in all books on thermodynamics and most handbooks. As given by R. J. Durley[1] it takes the form—

$$W = A\sqrt{2g\,\frac{\gamma}{\gamma-1}\times\frac{P_1}{V_1}\left[\left(\frac{P_2}{P_1}\right)^{\frac{2}{\gamma}}-\left(\frac{P_2}{P_1}\right)^{\frac{\gamma+1}{\gamma}}\right]}$$

where W = weight of gas discharged per second, lb.
A = area of cross-section of jet, sq. ft.
P_1 = pressure on upstream side of orifice, lb. per sq. ft.
P_2 = pressure on downstream side, lb. per sq. ft.
V_1 = specific volume of gas on upstream side of orifice, cu. ft. per lb.
γ = ratio of specific heat at constant pressure to that at constant volume.

By transposition and substituting 1.406 for γ and $53.4T/P_1$ for V_1, we obtain a workable formula for air, namely,

$$W = \frac{2.04\,AP_1}{\sqrt{T}}\sqrt{\left(\frac{P_2}{P_1}\right)^{1.425}-\left(\frac{P_2}{P_1}\right)^{1.712}}$$

where T is the absolute temperature (deg. fahr.) on the upstream side of the nozzle.

This formula assumes frictionless flow and for practice a coefficient must be applied. This coefficient for a nozzle having a well-rounded entrance should be 0.97 for diameters below 1 in., 0.98 between 1 in. and 3 in., and 0.99 for nozzles over 3 in. in diameter. With larger nozzles the coefficient will remain very close to 0.99. This coefficient has been very carefully determined by Dr. Sanford A. Moss, as described in his paper on the Impact Tube.[1]

As P_1 is the upstream pressure and P_2 the downstream, the expression P_2/P_1 is less than unity and to raise this to a power is an awkward job. Also, as P_1 and P_2 are very nearly alike with a low water-column pressure, it is necessary to get the ratio to at least five places of decimals. Unless this is done the difference of the powers will not be correct and the air quantity will not be exact.

To avoid using numbers less than unity, it is more convenient to call $P_1/P_2 = R$, which is greater than unity; then raise the R's to the required powers and subtract their reciprocals. By this procedure we obtain a more convenient formula, namely,

$$W = \frac{2.04\,CAP_1}{\sqrt{T}}\sqrt{\left(\frac{1}{R}\right)^{1.425}-\left(\frac{1}{R}\right)^{1.712}}$$

where C = coefficient = 0.97 to 0.99
R = ratio of absolute pressure on upstream side of nozzle to absolute pressure on downstream side of nozzle: P_1/P_2, expressed to at least five significant figures.

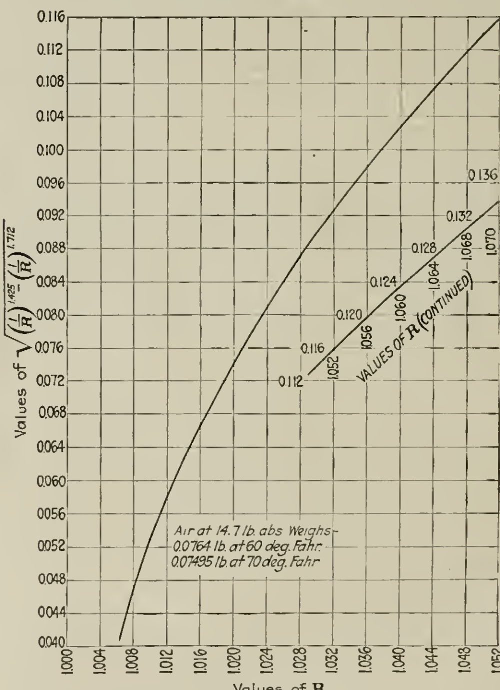

Fig. 2 Factors for Calculation of Air Flow by Rational or Energy Formula

Even with this modification it must be admitted the formula is cumbersome and for that reason the writer plotted the curve shown in Fig. 2. The abscissæ are values of $R = P_1/P_2$, which are therefore greater than unity, and the ordinates represent values of the complete radical $\sqrt{[(1/R)^{1.425} - (1/R)^{1.712}]}$. By means of this curve the process of figuring the weight of air handled is very greatly simplified.

After obtaining the weight per second, or per minute, of the air flowing, this should be changed to the volume handled by the pump so as to express it as a percentage of the piston displacement. To be perfectly logical, it should be expressed in cubic feet at the temperature of pump-cylinder intake as shown by thermometer G,

[1] Trans.Am.Soc.M.E., vol. 27, p. 195.

[1] Trans.Am.Soc.M.E., vol. 38, p. 761.

Fig. 1, and at the pressure of the cylinder intake, which is the vacuum shown by mercury column E. The cubic feet at this condition will be obtained by dividing the weight of flow calculated from the nozzle readings—water column F and temperature at H, Fig. 1—by the weight per cubic foot of air at the absolute pressure of vacuum read on U-tube at E and temperature measured at G, Fig. 1. The specific weight of dry air at any temperature may be calculated from the formula—

$$w = 0.1874 \frac{P}{T}$$

where w = specific weight at the pressure P and the temperature T, lb. per cu. ft.

P = absolute pressure at which the specific weight is to be found, lb. per sq. ft.

T = absolute temperature (deg. fahr.) at which the specific weight is to be found.

Slide-Rule Formula

For those preferring to use a slide rule for calculation, the following formula, based upon the principles of hydraulic flow, but modified empirically, will yield values very close to the longer formula already given, provided the nozzle water column is not over 18 or 20 in. Below this limit the agreement is quite close at most points, but varying about one half of one per cent, being that much high around 8 or 10 in. and that much low around 20 in. water column. The formula, however, is so easy to use that it is preferable to the longer one, and at low water columns—around 4 in.—it is certainly more accurate, as the ratios in the longer formula then become too small for accurate calculation. The formula is—

$$Q = 3.64\, Cd^2 \sqrt{\frac{HT}{P_m}}$$

where Q = cubic feet flowing per minute at absolute pressure of *downstream* side of nozzle and temperature shown by thermometer on *upstream* side of nozzle

C = coefficient of flow = 0.97 to 0.99 as before

d = diameter of nozzle throat (smallest section), in.

H = observed nozzle water column, in.

T = absolute temperature (deg. fahr.) shown by thermometer on upstream side of nozzle

P_m = absolute mean pressure: that is, the average between the pressures on upstream and downstream sides of nozzle, lb. per sq. in.

As Q will be expressed at pressure of downstream side of nozzle and temperature shown by nozzle thermometer on upstream side, it must be recalculated into volume at the vacuum shown by mercury column at E and temperature shown by thermometer at G, Fig. 1, as before. This is, of course, done by changing the volume inversely as the absolute pressures and directly as absolute temperatures. It should be noted that this formula expresses Q at downstream nozzle pressure, which is below atmospheric pressure by the amount of the nozzle water column observed.

Plotting Test Results

So much for methods of test and calculation. The next important step is the plotting of the results, and here we meet a fact which is very convenient for the experimenter. This fact is, that if the quantities of air at various vacua handled by a pump at constant speed are calculated into volumes at *atmospheric* pressure and the temperature of the intake to the pump cylinder (thermometer G, Fig. 1), and if these are expressed as percentages of the elapsed piston displacement of the pump cylinder, we obtain what may be termed "atmospheric volumetric efficiency" and this will be very nearly a straight line when plotted against vacuum. In Fig. 3 is such a curve, as shown by the diagonal line marked Atmospheric Volumetric Efficiency. This was taken from a small pump designed for moderate vacuum. In this diagram abscissæ represent vacua in per cent of the observed barometer and ordinates represent percentage volumetric efficiency.

Having arrived at this very simple form of volumetric-efficiency curve, the ease with which points along the entire line may be read will be noted. This should be compared with the difficulty of reading the true volumetric-efficiency curve, expressed at conditions of pump-cylinder intake, especially at the higher-vacuum points. In this part of the curve the line becomes so steep that close reading is very difficult, and correct plotting is almost impossible. The slightest deviation to the right or left in drawing the high-vacuum part of the curve may make a difference of several per cent.

It should be noted that the volumetric efficiencies shown by both lines in the diagram, Fig. 3, are expressed at the temperature of pump-cylinder intake; that is, by thermometer at G, Fig. 1. This is correct because this is the temperature at which the pump receives the air. The only difference between the two curves is the pressure at which the air volumes are expressed. The temperatures being the same, the volumes are inversely as the absolute

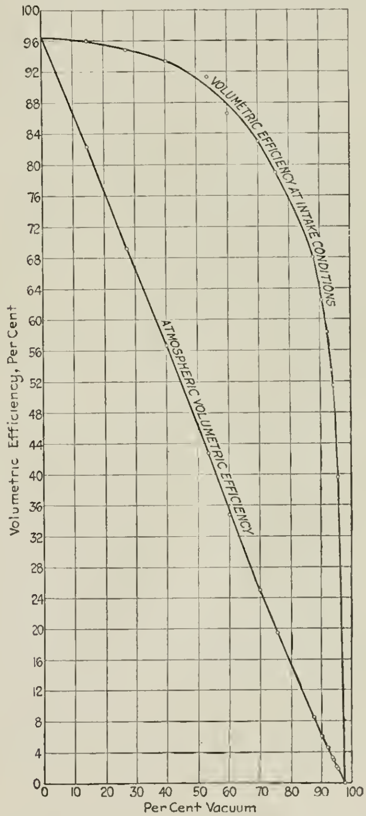

Fig. 3 Method of Plotting Volumetric Results

pressures, and as one of the pressures is atmospheric and the other the absolute pressure of the vacuum, the pressure ratio is simply the ratio of compression of the pump cylinder, provided the discharge is atmospheric. Therefore, with atmospheric discharge and having calculated and plotted the atmospheric volumetric efficiency, as shown by the diagonal, almost a straight line, the curved line of true intake volumetric efficiency may be obtained by multiplying the values on the diagonal line by the ratio of compression. Of course, if the pump discharge is not atmospheric, the values of the diagonal line should be multiplied by the ratio of the atmospheric pressure (barometer) to the absolute pressure of the vacuum at pump-cylinder intake.

Even after the true volumetric efficiency curve is plotted, it is usually easier and more accurate to obtain the true values by picking them from the diagonal line and multiplying these values by the pressure ratios. The steepness of the curve of true volumetric efficiency is too great to read accurately.

Evidence of Accuracy of Nozzle Tests

Right here is an excellent opportunity to say a few words to convince the skeptical of the accuracy of the low-pressure nozzle as an instrument for the measurement of air, as exemplified by these vacuum tests. In such a test we have at the lower right end of the diagonal line, the point showing maximum vacuum with closed intake, that is, with no air handled and no nozzle at all. Following up the diagonal line, the next four points were obtained with a $^5/_8$-in. diameter nozzle with water columns progressing from just under 4 in. to about 13 in. The next three points above these were with a 1-in. nozzle with water columns from approximately $3^3/_4$ in. to about $12^1/_2$ in. After these points follow nozzles of diameters 1.75 in., 2.00 in. and 3 in. with water columns up to just under 15 in., each nozzle being able to handle several different quantities. In such a vacuum test, then, we always have a series of nozzles, beginning in this case with $^5/_8$ in. diameter and ending with 3 in. diameter, with water columns of several heights for each one, and in a very large number of tests which the writer has made, never has there appeared to be any visible break in the curve except what was well within probable experimental errors, showing where one nozzle size left off and the next size began. Considering that each smaller nozzle leaves off with a relatively high water column and the next larger diameter begins with a low water column and furthermore that the smallest nozzle links up with the point of no nozzle and no air, this is also a very good argument that the formula used for calculating the quantity of air expresses the law of nozzle action very well, indeed.

Another point should be noted, and that is that in such vacuum-pump tests the upper left end of the diagonal line which, by the way, is also the upper left end of the true volumetric-efficiency line (the pressure ratio being unity), shows volumetric efficiency around 95 and 96 per cent. As at this point the machine is taking in air with atmospheric intake and also putting it out at atmospheric pressure, under these conditions the pump cylinder really acts as a rough kind of displacement meter checking the nozzle. Of course, with the extra large amount of air being handled under these abnormal conditions, a slight compression takes place inside the cylinder producing a little heating and other small losses which prevent the volumetric efficiency from actually reaching 100 per cent of the cylinder volume. If the nozzle were to show over 100 per cent volumetric efficiency we would know it was inaccurate. So far the writer has never seen a case of this sort, which cannot be said of some other methods of test he has observed and results he has seen reported in all seriousness. Being just under 100 per cent, and sufficiently under to be justified by working conditions, appears to the writer to be a very good argument for those who are skeptical. Other more scientific determinations, notably those of Dr. Moss, prove the result beyond dispute; but these vacuum-pump test curves have always served to quiet the objections of those who lack scientific knowledge, but who require conviction by an obvious, though perhaps approximate, method.

Effect of Valve and Piston Leakage

The effect of valve leakage has been mentioned as a cause for the departure of the atmospheric volumetric-efficiency curve from the straight line. It has been observed that with leaky valves the diagonal line will sag, especially at the high-vacuum or right-hand lower end. With appreciable valve leakage the line coming up and to the left from the closed-intake, maximum-vacuum point, will have a very decided bend in the first two inches of vacuum decrease. This bend in the line will be curved downward, which of course puts the curve lower for a given vacuum. When the points on this sagging diagonal line are multiplied by the ratio of pressures, as described, to obtain the true intake volumetric efficiency, this latter curve will simply lean further to the left. This means that the true volumetric-efficiency curve will not rise as rapidly as the curve corresponding to a diagonal atmospheric volumetric-efficiency line without sag. This again simply means that the true volumetric efficiency at a given vacuum will be lower, which naturally follows for a pump having valve and piston leakage.

With the above-described effect of leakage, it is clear that the true curves of a given pump cannot be drawn without actual nozzle-test measurements at several vacuum points near the maximum, as already described and illustrated in Fig. 3. For this reason any estimates based upon an assumed characteristic curve cannot be considered accurate, and if it is desired to be on the "safe side" without actual capacity tests, it is well to put an appreciable sag in the diagonal line used as a basis of estimation. This refers particularly to the upper two inches of vacuum.

The approved shapes of air-measuring nozzles will be described in the forthcoming air-compressor test codes now in preparation by the Power Test Codes Committee and the latitude to be allowed will be quite broad, just as long as the approach curve is well rounded. Special curves of compound radii have not been found to possess any particular virtue. All this is good news to the experimenter along these lines.

Nozzle Shapes

Something must now be said about the shape of the nozzles used. Coefficients already mentioned were for nozzles having well-rounded approach surfaces. With nozzles of this kind the coefficient has been found to be much more stable than when an attempt is made to use a so-called "sharp-edged" nozzle. It is a practical impossibility to make a nozzle with a perfectly sharp edge and it has been found that with the slightest degree of bevel or rounding or other deviation from the perfect edge, the coefficient may vary widely. With the nozzle having a rounded approach it has been found that the coefficient will not change with change of approach radius within wide limits.

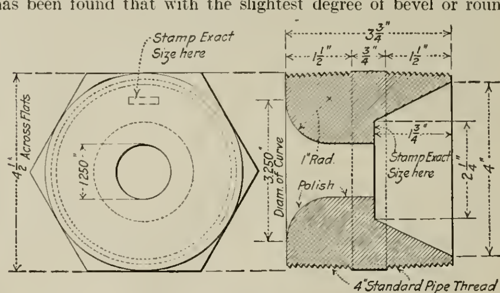

Fig. 4 Convenient Form of Air-Measuring Nozzle

Fig. 4 shows a very convenient form of nozzle. It is made with a pipe thread on both ends so that it can be used at will on the intake side of a vacuum pump, or on the discharge side of a compressor. The approach surfaces may have a radius of anything from 0.6 of the throat diameter, upward, with inappreciable effect upon the coefficient. The throat is followed by a straight or cylindrical portion. It is recommended that this be not less than $^1/_4$ the throat diameter, and it may probably be as long as the diameter without affecting the coefficient. Anything longer might bring in an additional friction influence to reduce the coefficient very slightly. A short straight portion has been found really essential to secure smooth flow.

Nozzle on Discharge Side

In some cases it may be desirable to put the nozzle on the discharge side of the vacuum pump. There are two objections to this, although they are not very serious. First, to eliminate the pulsations of the discharge two tanks will have to be put in series, with the nozzle in the second tank discharging to atmosphere. This aggravates the second objection, namely, the compression ratio, which would necessarily be increased, and therefore reduces the volumetric efficiency of the pump. This back pressure will also be different for different vacua and nozzle sizes. Any throttling between the two tanks to remove pulsation makes this much worse, and if the pulsations are not removed the readings of the nozzle will be incorrect. No throttling or otherwise damping of the pulsations of the nozzle water column will help, as the error comes in the pulsations of the actual air passing the nozzle. Throttling on the intake side is just what is required to get the vacuum, so that, all things considered, the nozzle on the suction side is undoubtedly to be preferred.

The Interpretation of Boiler-Water Analyses

By J. R. McDermet,[1] Jeannette, Pa.

With the increasing use of economizers, higher steam pressures and higher rates of evaporation, it has become as necessary to consider the corrosive effects of a boiler water as its scale-forming properties, if not more so. Because of this the author has prepared the present paper, which discusses briefly the limitations and applications of a technical or mineral analysis; advocates the use of a partial sanitary analysis as forecasting possible trouble due to pollution; and indicates the significance of the analysis for dissolved gases in relation to the conditions under which the water is used. A laboratory-procedure sheet is appended to illustrate and make useful the facts discussed.

The chemist in performing a technical water analysis proceeds along conventional methods and by processes of evaporation, selective solution, precipitation, etc., determines quantities which he may submit for consideration directly, calculate into terms of elemental ions and ion radicals, or hypothesize into various chemical compounds which are assumed originally to have existed in the water. Irrespective of how results are submitted it is possible to calculate back into ion values, to which may be applied certain generalizations—with the reservations, however, that the values are arrived at initially by inflexible methods and are connected with the properties of the water only through deductive relationships.

The dissolved chemical compounds of a water which will ultimately become scale on the boiler surface are relatively slightly soluble in a physical sense. Chemically they are characterized as feebly hydrolyzed salts, and as such they are capable of very little dissociation in water—and then only into a very limited number of ions or electrified particles: namely, those of the salt itself and those of the dissociation with water.

Corrosive salts, on the other hand, are characterized as being both hydrolyzed and highly ionized, one of ions at least being that of a strong acid or base. If the chemist's ionization constants are applied to a group of these salts representative of a natural water, a bewildering series of relationships develops, due to the number of ions and their mutual effect in displacing the equilibria of each other. Such a procedure, however, is irrational for three reasons: (*a*) Ionization constants are experimental factors determined for normal temperatures only and are not necessarily valid at boiler temperatures. (*b*) The water molecule is of the form $(H_2O)_x$, and water in its transition from liquid to superheated steam undergoes a change of molecular grouping from the dihydrol into the monohydrol form. This transition is not abrupt at the change of state but gradual with rise of temperature. The monohydrol form which exists in small proportions at normal temperatures apparently occasions both the hydrolytic and dissociation phenomena. (*c*) Concentration of impurities in a boiler operating at high rating and high circulation velocity varies widely at different points in the circuit, the concentration increasing at regions where the water is abruptly accelerated. The rule of experience alone is applicable to those classes of impurities.

The laboratory-procedure outline appearing later in the paper employs the following basis of distinction: The values obtained in the analyses are computed into those compounds which form scale as far as the analytical values suffice. In this grouping abnormal silica is the only constituent which is capable of causing corrosion and its action is mechanical in permitting local overheating. To the remainder of the impurities limiting values are assigned, either on a percentage or an integral basis, the integral values being reserved for those constituents which are virulent. Sodium is ordinarily a fictitious quantity employed to balance combinations, but if the water analysis indicates a possibility of danger according to the criteria employed, a real value of sodium is determined and compensation is allowed for its presence. Sodium is so strongly basic in its chemical properties that its behavior in solution can be predicted with some exactness, and the hydrolyzed products of sodium salts are themselves inhibitors of corrosion.

It is only the relatively pure waters which produce dangerous conditions, and as the sum of dissolved solids decreases the liability toward corrosion disproportionately increases. Beyond an impurity content of 300 parts per million, corrosive waters are almost invariably of abnormal chemical analysis so that the danger is immediately apparent. Below 50 to 60 parts per million, the technical analysis, even if it shows no unfavorable features, is usually insufficient unless the history of the origin of the water is definitely known. For such waters a sanitary analysis is a distinct contribution.

The Sanitary Analysis

The sanitary analysis is more truly a series of tests in which the reaction of the water is observed as indicative of the pollution which it has undergone, than a determination of foreign constituents. Technique has been so highly developed by the sanitary chemist that it is possible for him to tell from the values obtained in analyses the extent of the pollution and its sources—whether they be industrial, organic vegetable, or wastes from animal or human sources.

Industrial pollution usually manifests itself in the form of some characteristic compound which is a by-product of processes of manufacture. Aside from mine and paper-mill wastes, which usually reveal themselves unmistakably in the technical analysis, this class of pollution may occur in extreme dilution and yet be harmful in pure waters.

Under the heading of organic vegetable contamination may be grouped the products of algal growths, water plants in stagnant bodies of water, and the run-off from uncultivated land, particularly marshes, and deforested or forest fire areas. Chemically such contamination manifests itself either as acidity due to weak organic acids, or as nitrogen compounds. In the power plant the physical damage resulting from organic acids appears principally in the corrosion of saturated-steam lines, turbines, and vapor spaces of condensers; in other words, in apparatus where moisture accumulates from partial condensation. Unlike dissolved-gas contamination, the feed lines and boilers where the dilution of the acids is very great are reasonably exempt, and the corrosion does not exhibit its greatest vigor in a narrow zone of temperature. Undoubtedly the presence of dissolved oxygen accelerates the corrosion, but the organic acids polymerize or change their form rapidly and the action is not indefinitely cyclic as in the case of some mineral acids.

Nitrogen compounds—and in particular ammonia—originating in organic vegetable pollution confine their attacks principally to copper and brass fittings and the iron is exempt in the path of steam flow. In dead-end spaces serious corrosion may occur on both ferrous and non-ferrous metals, but aside from this the damage is usually inconsequential. Dissolved carbon dioxide in appreciable concentration due to bicarbonate alkalinity accelerates corrosion.

Sewage contamination may be classified as recent or remote, and further divided into household refuse and animal or human excrementitious matter. The latter, unless it exists in a quantity that contributes a dangerous chlorine content, sludges in the boiler and may be dismissed without further comment. Oleaginous matter and greases from household wastes if of recent origin contribute to foaming, priming and corrosion much as do organic acids if in considerable concentration. Sewage of remote origin which has been oxidized by aeration and bacteria action shows high nitrate content and sometimes nitrites, depending upon the extent of the natural purification. While the criteria in such cases are the nitrate content and the qualitative presence of nitrites, the introduction of both of these into a boiler water in any concentration is earnestly to be avoided.

The Dissolved-Gas Analysis

The analysis for dissolved gases is confined entirely to the determination of dissolved oxygen. The position of dissolved carbon

[1] Research Engineer, Elliott Company, Assoc.Mem.Am.Soc.M.E.

Abstract of a paper to be presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

dioxide is anomalous. The researches of the author have been concerned with the simultaneous removal of carbon dioxide and oxygen, and are inconclusive; the published results of Speller[1] incline to the view that carbon dioxide in the absence of oxygen is not prejudicial. Cases where corrosion directly chargeable to carbon dioxide has occurred have usually accompanied a high-bicarbonate alkalinity or been complicated by ammonium compounds. It is probable, however, that increased rates of driving will compel an entire reversion of attitude toward boiler-water alkalinities.

Analytical methods for determining dissolved oxygen are available in standard chemical textbooks, and methods of manipulation adapted to the engineer's needs have been discussed in the technical press.[2] Methods for determining dissolved oxygen fortunately and unlike other analyses on water determine definitely and directly the constituent sought, and it only remains to apply the information intelligently to the elimination of corrosion problems. While deterioration of the ferrous metals results at all stages of the water and steam cycle where water and oxygen are present as such, in all but two cases which have developed in the writer's experience alleviation has been sought only for steel-tube or cast-iron economizers, boilers, or hot-water feed lines. The characteristic manifestation is the wasting of cast iron and pitting of steel surfaces, sometimes accompanied in the latter cast by a pseudo-stalagmite formation.

It is impossible with commercial pipe materials to formulate an opinion as to how long a hot-water boiler-feed pipe system will last. It appears, however, that if the oxygen content is kept below 0.7 cc. per liter (0.7 part in 1000 by volume), the gas volume being reckoned under standard conditions, the life of the feed lines will be of such a length as to prevent ascribing the ultimate failure to oxygen. It may be taken as axiomatic, however, that the reduction of oxygen content to the lowest consistent value is always a desirable precaution.

Boilers that operate below rating rarely suffer any damage, whatever may be the oxygen content of the feedwater. As the rating goes up, however, damage appears, but if the concentration is kept below 1.0 cc. per liter the boiler seldom experiences pitting action. Boiler scale is a fairly efficient protective agent against this form of attack. Unfortunately, scales of predominant silicate or pure sulphate composition introduce a different corrosion loss, in that there is an amalgamation at the boundary between the iron surface and the scale through the intermediation of iron oxide. The use of mechanical tube cleaners in removing this scale results in a severe detrition loss from the iron surfaces which may very markedly shorten the life of the boiler. The removal of oxygen from the boiler feed to the extent that existing apparatus is able to accomplish it, does away with this amalgamating action, and these classes of impurities in the absence of heavy carbonate formations become self-scaling.

Boilers rarely present simple corrosion phenomena. Usually trouble arises from a complexity of causes. Corrosive dissolved solids which yield free acid radicals and dissociated acid radicals and dissolved oxygen are mutually accelerants of pitting action. With such boiler waters the removal of dissolved oxygen is a worth-while alleviation and a guarantee against regenerative action with a stable acid ion, but it is not a cure. Chemical treatment of the water is the most logical corrective if it is properly controlled and is not based on excessive alkalinities; but in practice the results obtained are usually far short of the ideal and need to be supplemented. The pitting of the surfaces presents the same general appearance. Where it is directly chargeable to dissolved gases the action is more or less selective, in that the area of greatest virulence is confined to parts where the circulation is sluggish, and entirely to the water space. In boilers subjected to severe acid corrosion, however, the pitting may extend into the steam space.

The corrosion of a cast-iron economizer likewise presents two aspects. The corrosion of cast iron in its initial stages is more rapid than that of steel, but the adhering residue products from the corrosion—graphitic carbon and silica—immediately form a protective coating which arrests further action. Cast-iron economizer corrosion is due to the continuous removal of the protective coating, has most nearly the appearance of erosion, and takes place in the headers and tube ends where water velocities are changed. This erosive-corrosive action will disappear if the oxygen content of the feedwater is kept below 0.7 cc. per liter, provided that the water does not deposit scale on the economizer surfaces. Economizers in the past have been principally waste-heat adjuncts operating between the extreme temperature limits of 90–250 deg. fahr., and if these limits are extended in future practice it will doubtless be necessary to lower further the oxygen value. Where the temperature and character of water combine to produce scaling on the cast-iron tubes which necessitates the periodical use of mechanical tube cleaners, the safe oxygen limit is automatically reduced to 0.3 cc. per liter. The tube cleaner not only removes the existing protective coating which has formed, but disturbs the surface layer so that a new one is slow in forming.

Jacobus and Speller independently and by different methods have established the value 0.2 cc. as the maximum oxygen content which will prevent accelerated corrosion in a steel-tube economizer. The allowable content which will permit the realization of a profitable operating life from the economizer may conceivably be lower than 0.2 cc. per liter, but this can be determined only after years of experience.

The most virulent steel-feed-pipe corrosion occurs between the temperature limits 180–200 deg. fahr; and no such range is exhibited by the steel-tube economizer. Water in its passage through and temperature elevation in the economizer gradually rejects a portion of its dissolved gases in the form of bubbles which cling to the tube wall and by coalescence establish for themselves a slower rate of travel than the water, whose velocity is materially below the region of turbulent flow. Besides materially reducing conductivity, these bubbles through their oxygen content both occasion the corrosion and distribute it over the entire surface.

The characteristic corrosion phenomena in the case of steel-tube economizers are pit holes. The primary cause for these may be exceedingly small pieces of imbedded mill scale or segregated impurities in the metal which form electric cells and occasion roughness, or an initial roughness on the surface to which the bubbles of gas adhere and produce minute air pockets. The appearance of a pit hole is accompanied by a stalagmite or barnacle-like growth of corrosion products completely covering the pit hole and projecting above the surface. These barnacle-like protuberances consist of three successive layers of iron hydroxides in the order of their proximity to the iron surface, $Fe(OH)_2$, $Fe_3(OH)_8$, and $Fe(OH)_3$, which in their dehydrated forms correspond respectively to the ferrous, black, and red oxides of iron. The hydroxide $Fe_3(OH)_8$ only is adherent, and constitutes the binder and the bulk of the volume. The growth of these projecting surfaces further arrests the bubbles and the electrolytic potentials accelerate the action, but all causes combine to keep it very localized. The result is a punctured surface.

LABORATORY PROCEDURE IN WATER ANALYSIS

1 If the water originates with the Condenser Division as a water for circulation, perform (7), calculate according to (8), and report on this basis.

2 If the sample originates with the Air Separation or Research Divisions, perform the analysis according to the detailed procedure which follows. A memorandum from the chief of the division concerned will be issued covering as far as data permit the following facts:

- *a* Purpose of the analysis
- *b* History and origin of the sample
- *c* Any physical observations which would direct a preponderance of suspicion toward peculiarities to be expected in the analysis.

3 Record all numerical results in parts per million (p.p.m.)

4 Record from observation in clean glassware qualitatively—

- *a* Turbidity
- *b* Presence of visible suspended matter
- *c* Color
- *d* Odor hot
- *e* Odor cold.

Boiler Tests with Pulverized Illinois Coal

By HENRY KREISINGER, MILWAUKEE, WIS.,[1] and JOHN BLIZARD, PITTSBURGH, PA.[2]

In this paper the author presents a summary of the results obtained in an extended series of tests of a 468-hp. water-tube boiler fired with pulverized Illinois coal.

The results show that, contrary to the customary specification, it is not necessary to pulverize the coal to the extreme fineness of 85 per cent through a 200-mesh screen in order to get good combustion and good efficiency. This ability to burn coarser coal means increased capacity of the pulverizing mills and decreased cost of coal preparation.

The results also show that it is not necessary to dry coal to about 1 per cent moisture in order to burn it successfully in pulverized form, and it is stated that with most eastern coals drying is not at all necessary.

Good results can be obtained when the coal is burned at rates varying from 0.5 lb. to 2 lb. per cu. ft. of combustion space per hour, and the best results at a rate of 1 to 1.5 lb.

THIS paper gives the summary of the results of a series of 11 tests made on a 468-hp. Edgemoor boiler equipped with a Foster superheater and fired with pulverized coal at the Oneida Street Station of The Milwaukee Electric Railway and Light Company, Milwaukee, Wis. The tests were made by the Fuel Section of the U. S. Bureau of Mines in coöperation with the Research Department of the Combustion Engineering Corporation. The powdered-coal equipment was designed and installed by the Locomotive Pulverized Fuel Company. The coal burned in these tests came from the Illinois coal field. The object of the tests was to determine what overall efficiency can be obtained with pulverized Illinois coal under various conditions of furnace operation and different preparation of coal as to degree of fineness and percentage of moisture.

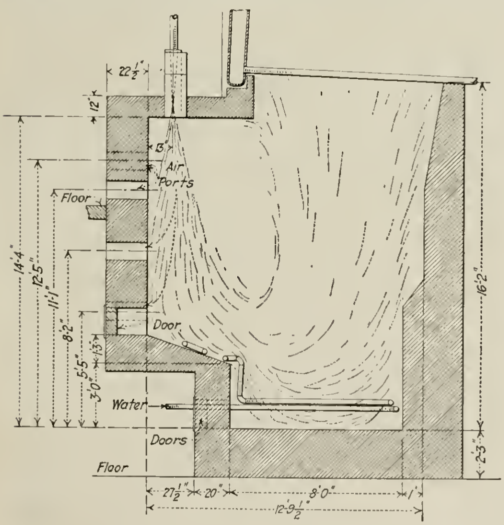

Fig. 1 Section through Furnace, Showing Arrangement of Burner and Cooling Coil over Hearth and Near Bottom of Furnace

The tests were made in a thorough manner, everything being done to make the results accurate and reliable. The pulverized coal was weighed in specially designed tanks placed on platform scales as it was supplied to the furnace. The tests were from 17 to 25 hours in duration.

Tests Nos. 28 to 30, inclusive, were made with the usual preparation of coal as it is burned in the plant under ordinary operating conditions. Test No. 31 was made with the same condition of coal as the three previous tests, but with the furnace provided with a cooling coil over the hearth and along the walls near the bottom of the furnace to facilitate the removal of ash. Tests Nos. 32 to 35, inclusive, were made with the same furnace arrangement as test No. 31, but with the coal pulverized to a lesser degree of fineness. Tests Nos. 36 to 38, inclusive, were made with the same furnace arrangement as in the previous four tests, but with undried coal.

Fig. 1 shows the arrangement of the burner and the cooling coil over the hearth and near the bottom of the furnace. The cooling coil consisted of three lengths of 2-in. pipe over the hearth and two lengths along the side walls and the rear wall. The total surface of the coil was 48 sq. ft.

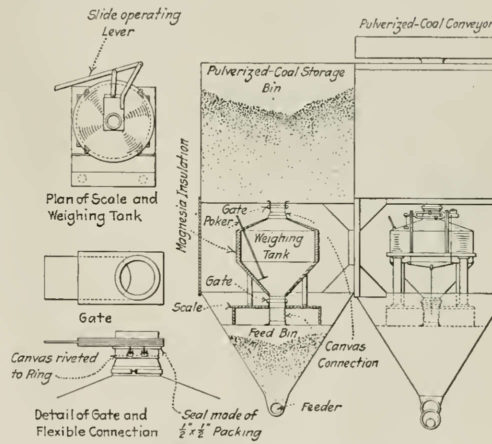

Fig. 2 Coal-Weighing Apparatus Used in Tests

Fig. 2 shows the coal-weighing apparatus, which was placed between the storage bin and the feed bin. There were two burners and two feeders, and the coal to each feeder was weighed separately. The weighing tanks were connected to the storage bins and the feeder bin by flexible canvas connections to permit weighing and to prevent the coal dust from escaping into the room when the weighing tanks were filled and emptied. The tests were started and closed with the feeder bins empty.

The feedwater was weighed in two water tanks placed on platform scales. The water supplied to the cooling coil was measured by a 2-in. water meter which was calibrated at the rate of feeding the water through the cooling coil, and its measurements were found reliable to within less than one-half of one per cent.

Flue-gas samples were taken at six points in the uptake and collected over one-hour periods. Flue-gas temperatures were measured with thermocouples at the same six points where samples were drawn for analysis, and readings were taken every 15 min. The flue-gas temperature given in Table 1 is the average of the measurements with the six couples.

Results of the Tests

The results of the tests are given in Table 1. The quantities of heat absorbed by the boiler, superheater and cooling coil, when the latter was used, are itemized separately. In the heat balance the losses by radiation are given by a separate item. In a series of tests on the same boiler and setting the radiation loss per square foot of exposed surface should be nearly constant and should vary only slightly by the capacity developed by the boiler. For the calculation of the radiation loss it was estimated that 250

[1] Cooling coil in operation during first $8^1/_2$ hours of test only.

B.t.u. were lost per sq. ft. of the exposed surface per hour when the boiler was operated at 100 per cent of rating, and 350 B.t.u. when operated at 200 per cent of rating. The radiation loss was calculated according to the percentage of rating developed. These calculations of the radiation loss leave the true "unaccounted for," which consists of errors. In a series of well-conducted boiler tests this true "unaccounted for" should be close to zero and should vary on both sides of the zero line according to whether the plus or minus errors predominate.

Effect of Fineness on Results of Tests

It has been customary to state that in order to get good results the coal must be pulverized to a fineness of 95 per cent through a 100-mesh screen and 85 per cent through a 200-mesh screen. Table 2 gives the results of complete sizing tests of the coal burned in Tests Nos. 32 to 35, inclusive. The coal was much coarser than specified by the foregoing statement. The results of these tests seem to indicate that it is not necessary to pulverize the coal to the extreme fineness of 85 per cent through a 200-mesh screen in order to get good combustion and good efficiency. The completeness of combustion seems to be more a matter of a proper furnace and burner design and the right way of supplying air than of the fineness of the coal. The losses due to coarseness of coal would be shown by the greater percentage of carbon in the refuse. The average loss due to this cause for the four tests with the coarser coal is 0.7 per cent. The average of this loss for the previous four tests is 0.6 per cent. The averages of the efficiencies are very nearly the same.

TABLE 2 RESULTS OF SIZING TESTS OF COAL BURNED IN TESTS NOS. 32-35

Test No.	—Percentage of Coal Passing Through Screens— 20-mesh	40-mesh	100-mesh	200-mesh
32	99.9	99.2	93.2	67.0
33	99.9	99.2	93.1	70.1
34	100.0	98.9	90.8	65.5
35	99.8	98.0	88.6	64.0

The ability to burn coarser coal means increased capacity of the pulverizing mills, and decreased cost of coal preparation.

Effect of Moisture in Coal on Results of Tests

Another statement that has been generally accepted is that coal must be dried to about 1 per cent moisture in order to be success-

On the Organization of an Engineering Society

By Morris Llewellyn Cooke,[1] Philadelphia, Pa.

The place which the engineer has come to occupy in our social economy suggests a reconsideration of a type of association and organization adopted at a time when the conception of the field of engineering was much more restricted than it is today. A gradual amplification of the definition of engineering and some regrouping of the divisions of engineering practice may be expected. While looking forward to a large and more or less immediate increase in the ranks of organized engineers, we need more than anything else an increase in the activity of the individual member. The structure of our present organization makes almost no provision for deciding in democratic fashion what is to be done and who is to do it. Bold and far-sighted administrative leadership in the execution of plans is difficult under the type of board or committee control which obtains in most societies of engineers.

To take advantage of present opportunities for public service, professional solidarity is the first requisite. But to wield wisely our rapidly accelerating power we need such democratic control of policies and such constant publicity as will permit larger individual initiative and even aggressive leadership in the execution of plans.

Before one can discuss intelligently the characteristics of the organization best adapted to an engineering society, the attempt must be made to reach some conclusion as to the essential nature of an engineering body and as to the scope of its functioning in the whole scheme of human society. Here again as in industry—and in life itself—before we can plan effectively we must know something as to the desired product, both as to its quantity and kind. We must know what is to be the relationship between organized engineering and other agencies through which the human spirit functions.

H. G. Wells tells us that even before "the coming of speech" there was the "fear of the old man of the tribe."[2] Here apparently is to be found the very beginning of our concepts of government, of sovereignty and of society. That we did not progress very rapidly in this matter of community organization is shown by the fact that some millions of years later we find Louis XIV proclaiming himself—and himself alone—to be the State. *"L'etat, c'est moi."*

A good many people still look upon the Government—and the State—as something entirely apart from themselves, as residing largely in a single individual or at least within a very small coterie of those holding high office. Indeed, today's popular concept of sovereignty has not in many respects progressed much beyond that entertained by cave men.

But this doctrine is rapidly becoming too simple to command the confidence and loyalties of a race kept spellbound by the continuous revelations of science as to the interrelations of natural phenomena. Everywhere the nations are seeking an organization for society which shall be much more highly differentiated than that which obtained during the immemorial reign of force. We seek to distribute the function of leadership. In our own land every man is protected by statute in being a bit of a sovereign. The recognition of essential law, the spread of education, the elevation of mind over matter, and the philosophy of Christ make possible "preeminence by consent"[3] rather than by force. It is because of this new type of environment quite as much as on account of the ever-widening development of science and its application in the field of engineering that the engineer is being accorded a rapidly advancing status in modern civilization. Any one who has lived near to the brain and heart of our own Government—as some of our profession did during the war—knows that even in the face of grave danger the substance of unity is frequently missing in such ideas as sovereignty, government and the State. Of course one of the tenets on which our own nation was founded was the complete separation of Church and State. This action grew out of a clear recognition of one master division in sovereignty as it affects the lives of men. More recently we have seen the development of the organization of the labor movement in more than one nation to the point where tacitly or otherwise it exerts in some measure the prerogatives of sovereignty. Again, only the blind can fail to see the business groups in every nation exerting powers of sovereignty, sometimes through governmental channels and at other times entirely independent thereof. I have of course reference only to activities on the part of organized labor and organized capital which may be said, generally speaking, to have or to warrant the approval of organized society. Both groups of course at times seek to trespass, and as a matter of fact do err in trespassing beyond these bounds.

We should constantly have in mind that under present-day concepts the bases of national sovereignty lie ultimately in the wills of men. It is on this foundation that we Americans have reared the house of our national life with its various phases—industrial, social, professional, religious, etc. Threading its way through them all like the framework of a building in process of constant construction and reconstruction we find the Government coördinating—sometimes unifying—the life of the people. But never, let it be remembered, is government an end in itself.

In view of the foregoing, may we not altogether properly look forward to the day when the profession of engineering will be given that "preeminence by consent" which is more than an equivalent for sovereignty? It is altogether in the interest of society that we should prepare ourselves for such an "exercise of supreme authority" as will be consistent with the momentous content of engineering as it will be but a few years hence.

Competent observers outside the profession begin to sense the implications of our rapidly growing control of the bases of our common life. Thorsten Veblen refers to the profession as "the sufficient and indispensable general staff of the mechanical industries on whose unhindered teamwork depends the due working of the industrial system and therefore the material welfare of the civilized peoples."[1] Again, he says the industrial system "appears to be approaching a critical pass beyond which it will no longer be practicable...to entrust its continued adminstration to others than suitably trained technological experts." Equally suggestive of our rise to power are the titles of such recent books as Creative Chemistry[2] and The Conquering Engineer.[3]

The type of organization for an engineering society such as we seek is the one best adapted to make our group an effective cog in the whole scheme of social organization. No one engineering organization can seek its best development and largest future except as one link in the totality of the profession. It follows, then, as has been said on another occasion, that—

> Only through the solidarity—the essential oneness—of all the branches and divisions of the engineering profession will it be possible first to formulate and express an adequate sense of our public responsibilities and then to develop and use our collective initiative in their execution.[4]

We need an emphasis on the common characteristics of all good engineering in order to reveal the unity of the engineering approach. This once established we shall have what some one has called "mass morale"—an absolute essential for our highest professional development.

In the light of this definition of the function in human society of engineering and the engineer, our codes and definitions and standards of one kind and another take on a new importance. The dedication of the recently organized Federated American Engineering Societies exclusively "to the service of the community, state and nation" was indicative of a widespread feeling that the engineer can know but one allegiance when public and private interests are in conflict. Theoretically, this has been our pro-

fessional attitude for some time past, as it has been of the doctor and the lawyer. But in the further step the Federation took with regard to publicity, service to the community as our objective becomes something more than a phrase. Under Article X of the Federation's Constitution it is provided that the "organization shall stand for the principle of publicity and open meetings," which through a by-law is interpreted to mean that "the privilege of attendance at all meetings of the American Engineering Council, of the Executive Board and of Committees, when not in executive session, shall be extended to any proper person;" also that "any proper person shall have the right to inspect and make true copies of the official records of all meetings of the Council, the Executive Board and Committees." By these stipulations the activities of the Federation are quite as open to view and review as those of the Government itself. This attitude is entirely in keeping with the profession's obvious destiny. Every engineering organization should adopt these practices, to the end that this attitude in favor of publicity and against secrecy become the hallmark of engineering. As a profession we cannot be too grateful to the sponsors of this fundamental change. Engineers now and in the future should jealously guard against any backward step in this matter. How better than through these provisions for publicity "shall we let the people know that we are building knowledge for their use, that we are serving every interest that they have and yet are slaves to none of them, that we will listen to every thought they bring and yet will weigh and value them with thoughts of other men in mind."[1] In fact, in the absence of studied and widespread and uncomprising publicity, such power as is undoubtedly coming to the technological group may become a menace. Unless we seek and obtain far-reaching public sanctions as we go along, something akin to a Frankenstein may result.

Consideration of the conditions under which engineering has more and more come to be recognized as a profession suggests that it will be increasingly difficult for the individual engineer to do his job except as he has a part in a highly differentiated professional engineering organization. This interdependence is well expressed by an English economist, R. H. Tawney:

> A profession may be defined most simply as a trade which is organized, incompletely, no doubt, but genuinely, for the performance of function. It is not simply a collection of individuals who get a living for themselves by the same kind of work. Nor is it merely a group which is organized exclusively for the economic protection of its members, though that is normally among its purposes. It is a body of men who carry on their work in accordance with rules designed to enforce certain standards both for the better protection of its members and for the better service of the public. The standards which it maintains may be high or low; all professions have some rules which protect the interests of the community and others which are an imposition on it. Its essence is that it assumes certain responsibilities for the competence of its members or the quality of its wares, and that it deliberately prohibits certain kinds of conduct on the ground that, though they may be profitable to the individual, they are calculated to bring into disrepute the organization to which he belongs. While some of its rules are trade-union regulations designed primarily to prevent the economic standards of the profession from being lowered by unscrupulous competition, others have as their main object to secure that no member of the profession shall have any but a purely professional interest in his work, by excluding the incentive of speculative profit.
>
> ....The rules themselves may sometimes appear to the layman arbitrary and ill conceived, but their object is clear. It is to impose on the profession itself the obligation of maintaining the quality of the service, and to prevent its common purpose being frustrated through the undue influence of the motive of pecuniary gain upon the necessities or cupidity of the individual.
>
> The difference between industry as it exists today and a profession is, then, simple and unmistakable. The essence of the former is that its only criterion is the financial return which it offers to its shareholders. The essence of the latter is that, though men enter it for the sake of livelihood, the measure of their success is the service which they perform, not the gains which they amass. They may, as in the case of a successful doctor, grow rich; but the meaning of their profession, both for themselves and for the public, is not that they make money but that they make health, or safety, or knowledge, or good government or good law. They depend on it for their income, but they do not consider that any conduct which increases their income is on that account good. And while a boot manufacturer who retires with half a million is counted to have achieved success, whether the boots which he made were of leather or brown paper, a civil servant who did the same would be impeached.[2]

Again, as an integral part of any discussion of engineering organizations should come a discussion of the organization of engineering itself. Its development had been so largely haphazard that the resulting fabric is not one that yields readily to logical organization. Indeed, our engineering front is very ragged. Here and there we find salients pushed so far out into the regions of the unknown as to constitute almost a menace to balanced progress—simply a useless diversion of energy and funds. Every one of us can think of phases of engineering upon which time and thought are devoted entirely out of proportion to the importance of the matter when considered as a part of the whole scheme of engineering progress. On the other hand, every one can suggest matters calling for investigation, coördination, and pure research, and for the lack of which whole sections of our engineering front are held back. I have specially in mind at the moment our own specialty of management. We know almost nothing about it except in an empirical sort of a way. And yet for the lack of such laws and data as would doubtless result from broad-visioned experimentation in administration and management, almost every undertaking of man is conducted under a heavy preventable loss. There are few studies in this field which insure an immediate or measurable financial reward, hence this master subdivision of engineering receives in a twelve-month probably not as much financial support as goes into researches on the incandescent lamp every day in the year.

One of the world's greatest authorities on organization, Wilhelm Ostwald, has discussed this unbalanced state of knowledge in connection with the sciences. It is almost word for word applicable to engineering:

> For what is organization? What is the meaning of this process that has proved to be of fundamental importance in all departments of our present social life? The word relates to the existence of the characteristic desired in living beings, in organisms, and it is among them, in fact, that we find the principles in question put into practice and their existence long recognized. We know that a living creature is all the more perfect in proportion to its having been able to develop proper organs for the varied functions peculiar to its existence, and in proportion to its assuring more completely the common and organized coöperation of these organs by means of a central nervous system. In connection with all organization there come into question two related yet distinct operations: on the one hand a division of functions and their apportionment to special organs for the purpose of having each single function all the more perfectly carried out by the particular organ formed for it; and secondly, a coördination of these single distributed functions in the interest of their common service in such a way that each single organ carries out its activities, in point of space as well as of time, so that it thereby produces the greatest gain for the whole organism. Therefore the distribution of functions and the combination of functions are the very essence of organization, and so we shall not be able to organize science otherwise than by separating its functions and then by reuniting them in collective efficiency.
>
> A suitable division of functions implies, moreover, a knowledge of the separate functions—i.e., it presupposes a general survey of the total range of the sciences, and demands therefore a system of them, and this is shown to be the great practical problem that must be solved if we are to organize scientific progress logically.
>
> One occasionally hears the objection raised that an organization of the sciences is not to be thought of, for the reason that science is the highest manifestation of spontaneous mental activity, and therefore is to be gratefully received, but should not be consciously and systematically directed toward definite problems and fields of work. Such an objection is not justified, for the reason that all human progress in all departments rests upon the fact that those things which have occurred heretofore unexpectedly and by chance are transformed into a systematized harvest in the field of human activity through our recognition of relationships established by law. Such an objection in the face of science has still less justification for the reason that science in its very essence rests, as we well know, upon the systematic, logical, and rational ordering of single facts.
>
> ....We are therefore confronted by the task of subjecting the whole range of science to the same organizing and systematizing process which has been carried out so successfully in single sciences, to the advantage of society as a whole.[1]

Before we organize new engineering societies or carry further the subdivision of existing ones into professional sections, we should put engineering through a systematizing process somewhat similar to that suggested for the sciences.

Perhaps of more immediate interest to us is the fact that organization is an attribute of life. We can group inert things as we do when we gather so many potatoes into a basket to make a bushel. But this is "aggregation, not organization." We management engineers should be the first to recognize that it is impossible to organize any but living entities. An engineering

society in reality gets but little benefit from those who are "simply members." Their dues of course help. But one of the major tasks of all engineering organizations and societies is to get every member genuinely into some part of the play.

While it is an important task, it does not appear to be a difficult one. We are probably within the actual facts in assuming that not 50 per cent of the members of A.S.M.E. attend even one engineering meeting a year, and that less than 10 per cent of the 13,000 members indulge in any other form of organized engineering activity not directly associated with earning a livelihood. This condition exists largely because to remedy it never seems to have been set up as one of our problems. Possibly it has been assumed that to stagger along under the load of the inertia of the inactive 90 per cent is inherent in our proposition. In fact, I am not sure that we have not done many things which directly encourage this attitude of non-participation. The withholding of the vote from junior members apparently has had this effect. In fact, our whole attitude toward young men is one which holds them at arm's length and further seems quite out of harmony with modern thought. The world at large is coming to hold that progress is to some extent at least woven out of the thoughts of the less able members of the community—certainly that even the least conspicuous have an altogether vital contribution to make.[1]

Can we not look forward to the day when to be "simply a member" of any professional organization will be as exceptional as it is today to be "something more than a member?" One way to bring this about might be to have one section—possibly the Management Section—either make activity of some kind a test for membership or set up an active list on which would be carried only the names of real participants in section work. There are now so many different ways of coöperating to further the aims of an engineering society that every one can do something.

We have sought to see in the organization of an engineering society something far deeper and broader than the structure of its government—particularly because of the obvious application in this field of the adage, "The least governed are the best governed." Nevertheless administrative and managerial policies are of the essence of our task.

For some years past—particularly since the war—there has been a marked increase in the activities of all engineering organizations. For the most part this added activity has expressed itself in increase of membership campaigns, the multiplication of technical literature, and to a lesser extent in interest in public affairs. Practically no thought has been devoted to a study of the structure of the organizations through which we make ourselves felt. Engineering organizations are for the most part identical in type. This common scheme of association was designed at a time when there was no recognition of the field and function of the engineer as we understand it today. No material change has been made in the government of these societies except in the case of certain national associations which have slightly democratized their election machinery and more recently granted some measure of autonomy to local branches. This current type seems to err (1) in that there is little opportunity for a continuing and effective administrative direction and control, and (2) that there is almost no provision for the development of what might be termed the non-technical mind of the profession.

The constitution of every engineering society with which I am familiar not only places the administrative direction in the hands of a board, but makes no provision for a genuinely responsible administrative and managerial official. As I have elsewhere pointed out, the secretary of every engineers' association is by its constitution and by-laws subordinate to the board, not only in the sense that he is supposed to operate his office generally to the satisfaction of the board, but in the further sense that he is not supposed to inaugurate policies or to act in matters of any importance except in an effort to execute what has become the will of the board. In other words, the secretary of our typical society—nominally its manager—is not in reality a manager. Hence we have no one in the organization who in any way corresponds to the president of a company. I do not know that we should have. But I am sure that we have a very primitive and halting type of group direction and control through the board of directors. The weakness, in my opinion, does not grow so much out of the group control as out of the fact that the group gives very little time to the job. In the A.S.M.E. this is not more than thirty hours a year on the average.

The presidency as a rule goes to some distinguished member of the profession, and not always with regard to his capacity for administrative work. Even the best administrator would have little opportunity to accomplish results in the usual one-year term. Almost before the president knows what the problem is, his term of office expires. Usually our presidents are chosen in the midst of their professional success. They are busy men and cannot give all their time to the job. It would help if the president could be given duties somewhat comparable to those of the chairman of the board in private organizations. Such an arrangement would certainly meet the requirements for some years to come. If, however, the operations of engineering organizations grow as rapidly as now seems possible even for this post, effective service will mean more than a one-year term.

But the organization of the board and the functions assigned to a one-year president are relatively unimportant compared to the status given the secretary, executive secretary, or managing director who is charged with the administrative conduct of the society's affairs. If we are to attract to such posts and hold men capable of expressing the power and sweep and vision of present-day engineering, we need some *constitutional* delegation of responsibility to an official selected by the board, holding office at the pleasure of the board, and of course reporting to the board—but only in the sense that any president of a corporation reports to his board or that a city manager reports to the commission for the time being in office. The present arrangement, even when the secretary acts as if he had the authority, gives too much opportunity for avoiding responsibility in debatable matters. The present system too frequently results in the doing of the obvious, and in a more or less insipid and even halting administration. The board acts in a way as a buffer between the membership and the secretary. It has the power, but practically always refuses the responsibility which should go with it. The administrative official, even if fairly successful, is so in spite of the obvious handicaps.

The effort to reduce all engineering organizations to a single type is futile. Local initiative and even variation are to be encouraged, but as engineers, our obvious duty is to eliminate unnecessary overlap in field or function. Wherever economies can be effected by setting up joint agencies, this should be done.

In the matter of developing the non-technical mind of the profession and affording it adequate opportunities for more or less regularly recording its judgments, almost nothing has been done. In the absence of such a "mind" it is worse than futile to assume that any one can "speak" authoritatively for the profession. Now and again the effort is made to voice the engineering opinion of the nation, but it comes from such shallow waters that action is but little affected. But if we can organize to really sound out the depths of our professional thought, the judgments so rendered are certain to be woven into the very fabric of the future.

It has been said that "in respect of any undertaking, centralization, i.e., the administrative and management control recommended above, is the way to do it, but it is neither the correct method of deciding what to do nor the question of who is to do it."[1] Except as to the purely technical phases of engineering, there is practically no organized effort being made to decide what our engineering societies should be and do. In fact, it is only recently that a program for the profession has been recognized as a problem. It is quite unusual for an engineering society to afford an opportunity for the discussion of those society and professional affairs not directly related to specific engineering details. Every engineering organization should devote its best energies to developing a method whereby the task of the engineers as an organized group can be considered and outlined, and then kept constantly abreast the best thought of the profession and of the times. Either under the auspices of The Federated American

THE DESIGN OF LARGE LOCOMOTIVES

(Continued from page 314)

Blow-off cock handles should be so located that they can be operated by a man in position where he can see the water glass, and preferably without leaving his seat. The water glass, steam gage, air gages, etc., should be so located that they can be seen by the engineer when in usual position on his seat.

The throttle lever, power reverse lever, cylinder-cock lever, sander valves, brake valves, etc., should be located where the engineer can reach them handily when sitting in usual position on his seat or sitting with his head out of the window. It appears like a small detail, but it is a worth-while one to locate the straight air valve where it can be reached easily by an engineer when in such a position that he can see a man at the back of the tank giving signals for coupling to a train.

The lubricator must be at such a height that a man can see the feeds, and it must be high enough to avoid pockets in the oil pipes. It must be far enough below the cab roof to be filled easily.

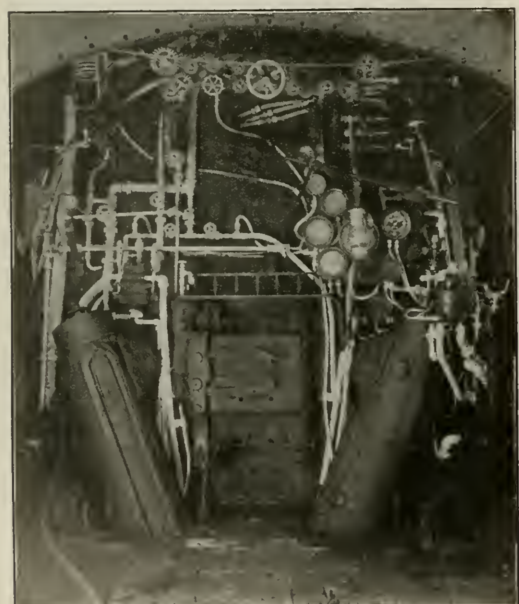

Fig. 6 Location of Boiler Back-Head Fixtures in Large Locomotive

Cab equipment requires careful study and it is difficult to locate the various appliances by drawing, but it has been done. A cab with a large amount of equipment on the boiler back head, yet which is regarded as being reasonably convenient, is shown in Fig. 6.

The use of clear-vision windows has made it somewhat difficult to arrange the seats so that either seat or window will be a height to suit different men. This problem, however, has been solved for one road by its motive-power department chief, who has developed an adjustable seat made of steel and having a spring cushion and an upholstered back. The back being secured to the seat and independent of the back of the cab prevents any vibrations resulting from shaking of the cab wall.

Tender Capacity

Tender capacity should be arranged so as to reduce to a minimum the time a locomotive is detained from the productive work of hauling trains for the purpose of taking water and fuel. This implies large fuel and water capacities, but in arranging for suitable tender capacity care must be taken to avoid unnecessary weight, as any increase in the weight of the tender produces an equal decrease in the weight of train that can be hauled behind the tender.

Tender fuel space should be arranged so as to enable the locomotive to handle a full train with as few stops for fuel as may be feasible.

On territories equipped for water to be taken on the run or when stops for purposes other than taking fuel or water are made regularly at stations where water may be taken, the water capacity should be only sufficient to supply the locomotive when handling a full train, between water stations, with a moderate surplus for unusual delays.

On territories handling a large percentage of through trains with few stops, tenders of large capacity are desirable as they permit keeping locomotives more continuously at work. Where water is scarce and the supply has to be hauled to water tanks, tenders of large capacity are desirable as they reduce the number of water stations that must be maintained as well as the number of locomotives, cars, and men employed in hauling and handling water at these stations.

In addition to reducing time consumed by trains on the road, together with overtime pay to train and engine crews, large-capacity tenders effect a substantial saving by reducing the fuel consumed in starting and accelerating trains as well as the damage to locomotive machinery, draft rigging, tires and rail which frequently results from stopping and starting long freight trains. Train dispatching is simplified and the movements of superior and opposing trains are expedited, as a train which keeps moving interferes less with the movements of other trains than one which must stop frequently, thereby introducing uncertainty as to how long it will be detained.

BOILER TESTS WITH PULVERIZED COAL

(Continued from page 322)

fully burned in pulverized form. In order to determine to what extent this statement is true, tests Nos. 36, 37 and 38 were run with undried coal. The results of the tests show that the completeness of combustion was as good as with the dried coal. There was no loss due to CO in the flue gases and the losses due to combustible in the refuse averaged only 0.3 per cent for the three tests, which is in fact less than the average with the dried coal.

The losses due to moisture in coal of course increased 0.5 to 0.6 per cent, which increase is at the rate of about 0.1 per cent for every 1 per cent of increase of moisture in the coal. The average decrease in the boiler efficiency for the three tests is about 0.7 per cent, which checks closely the increase in the losses due to increased moisture in the coal. It seems, therefore, that it is not necessary to dry the coal down to 1 per cent of moisture in order to get good boiler efficiency. In fact, it seems that most of the eastern coals can be pulverized and burned with good results without drying.

Capacity of Boiler That Can Be Developed with Pulverized Coal

The capacity of boiler that can be developed with pulverized coal depends entirely upon the size and shape of the furnace. With the present knowledge of the art of burning powdered coal the best results are obtained when the coal is burned at the rate of 1 to $1^1/_2$ lb. per cu. ft. of combustion space per hour. Good results can be obtained when the coal is burned at rates varying from $^1/_2$ to 2 lb. per cu. ft. of combustion space per hour, which gives a considerable working range. In Table 1 the rate of combustion is given by item 12. The range covered by this series of tests is from 1.05 to 1.81 lb. of coal per cu. ft. of combustion space. If it is desired to operate the boiler at high rates of working, a large furnace must be installed, and the combustion space must be so arranged that the flames are given the longest possible path through the furnace. The design of burners and the admission of air are very important at high rates of combustion. It appears probable that future developments in the design of furnaces, burners and the air supply may make possible higher rates of combustion than the limit given above.

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

Losses in Convergent Nozzles

THE paper here abstracted, by Prof. A. L. Mellanby and Wm. Kerr, deals in particular with the anomaly of the velocity coefficients and especially with the falling off in the standard of performance of convergent-type nozzles with restriction of the range of expansion.

This fact has been thoroughly demonstrated by experiment and may be shown in the form of a curve representing the variation of the coefficient of velocity or of discharge with change of pressure ratio. This curve always shows continuous reduction of the coefficient of discharge with limitation of the range, thus apparently indicating higher proportionate energy losses for the lower fluid speeds, as, for example, in Fig. 1.

Curve 4, which is derived by Professor Gibson from experiments on an air venturi meter, demonstrates that this effect is common to the expansion of different fluids. Although the venturi form is apparently convergent-divergent, it is operating only as a convergent type within the expansion ranges to which the discussion applies, and from which the coefficients were obtained.

Fig. 1 shows coefficients of discharge. The velocity coefficients are directly comparable with these, but in general are slightly higher. The nozzle efficiency may be taken as given by the square of the coefficient of velocity; and, since the higher ratios show the lower coefficients and correspond to the lower speeds of flow, the efficiency is apparently poorer with the less rapid motion.

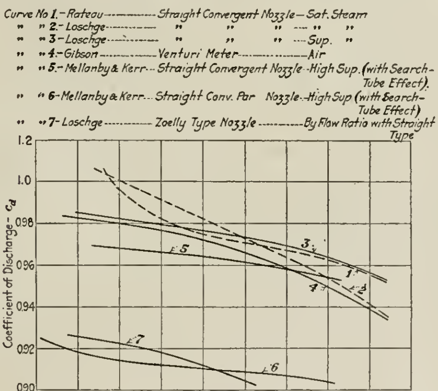

Fig. 1 Various Discharge Coefficients

Such a result is contrary to any preconceived ideas of the matter, as it would seem only natural to expect the best efficiencies at the lowest speeds. The anomaly so presented has been frequently remarked upon, and has created a feeling of perplexity that shows itself in the widely varied explanations that have at times been advanced.

The various hypotheses that would account for the vagaries of nozzle flow are presented and discussed by the author.

One hypothesis which they offer is that the non-uniform distribution of velocity across a section of nozzle might be conceived as independent of pressure variation, which might be considered due to boundary and viscosity effects and is actually known to exist in slower pipe flow. This is examined mathematically and at first glance appears to give an adequate solution, but does not, as the authors explain further.

To give a real explanation of the behavior indicated by the curves in Fig. 1, the authors endeavor to examine the causes underlying the growth of loss along the expansion.

The ordinary idea of nozzle loss is that it is mainly due to friction effects that increase rapidly with the speed. The authors, however, proceed to prove that e, which is the total energy loss per second in the nozzle, is not a purely frictional loss, and while such a loss may be involved in it, it is accompanied by another effect either of constant magnitude or increasing only with the low power of the speed, but sufficiently important to counteract definitely the natural influence of the normal frictional loss.

If two such loss effects exist and can—even imperfectly—be separated, it would be of interest to secure data as to the order of frictional resistance at high velocity speeds, and also whether these are at those speeds proportional to the square of the speed as they are at moderate speeds.

As regards the convergent nozzle, which is, by the way, the

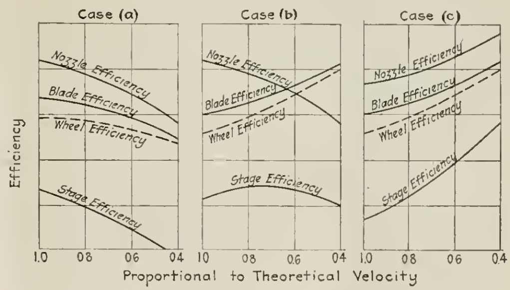

Fig. 2 Efficiency-Curve Forms

type most generally used in modern practice, there is direct experimental evidence that a velocity of efflux closely agreeing with that of sound presents the best condition, and the authors ask whether this is due to some particular virtue in this high speed, and whether this characteristic fact applies to the action on the blading or is peculiar to the nozzle alone.

Is it in brief the effect of the speed or something peculiar to the expansion? Fig. 2 shows three possible combinations of rational curve forms that could be used as a result of more or less accurate deductions from test figures, where nozzle and blade effects cannot be definitely separated. The wheel-efficiency curves represent a change of form due to the necessary consideration of mechanical losses. As regards the stage-efficiency curves, case (*a*) requires the highest speed, case (*b*) a figure somewhat lower, and case (*c*) very moderate values indeed.

All turbine designs may be classified under one of these cases. Case (*a*) depends for its development on the availability of better materials that would make possible the use of higher blade speeds; case (*b*) comprises designs based on the assumption that practically the best conditions have already been reached, while the designs of case (*c*) rely for the attainment of the ends on the multiplication of stages. Marine impulse turbines belong to this class, which may be partly due to the influence of some such conditions as are embodied in case (*c*), but also to the somewhat lower blade speed supposed allowable in marine applications.

The experimental method used by the authors consists simply in passing a search tube along the axis of the expanding jet, in conjunction with which accurate measurement of the mass flow is made. These observations are carried out on any given nozzle under fixed initial conditions of supply, which are so arranged that the expansion is confined to the superheat field.

The reheating effect on the fluid due to the losses in the expansion is determined from the equation—

$$0.718\left(\frac{V_1}{P_1}\right)^{1/2}\frac{G}{A} = \frac{r\left(1 - k - r^{\frac{n-1}{n}}\right)^{1/2}}{k + r^{\frac{n-1}{n}}} \qquad \ldots\ldots\ldots [1]$$

in which P_1 = pressure of supply, lb. per sq. in.
V_1 = specific volume, cu. ft. per lb.
G = mass flow, lb. per sec.
A = flow area, sq. in.
$r = P/P_1$ = pressure ratio at any point where pressure is P
k = reheating or loss factor
n = index of the law (PV^n = constant) for the reversible adiabatic in the field of expansion
= 1.3 for superheated steam.

Here k depends on A, which in certain cases may be measured and in other cases determined otherwise.

Either side of Equation [1] expresses the value of what has been termed the jet function, since certain important quantities that outline the jet conditions are embodied therein. Which side is used in any particular instance depends upon which variable is being considered. Thus to write the jet function F as—

$$F = 0.718\left(\frac{V_1}{P_1}\right)^{1/2}\frac{G}{A} \qquad \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

provides a form in which the flow area of the jet is the essential variable, and it is seen that this is simply inversely proportional to F. If the function is written—

$$F = r\,\frac{\left(1 - k - r^{\frac{n-1}{n}}\right)^{1/2}}{k + r^{\frac{n-1}{n}}} \qquad \ldots\ldots\ldots\ldots\ldots [3]$$

a form is obtained in which the loss factor is the important quantity considered. The relationship between k and F is not very direct, but, with F and r known, k can always be computed.

Again, it is easy to show that—

$$\left(1 - k - r^{\frac{n-1}{n}}\right)$$

is proportional to the kinetic energy of the jet; while—

$$\left(1 - k - r^{\frac{n-1}{n}}\right)^{1/2}$$

is similarly proportional to the velocity. Also the factor—

$$\left(\frac{k + r^{\frac{n-1}{n}}}{r}\right)$$

is in direct proportion with the specific volume of the fluid. These meanings for the detail factors are rather useful, and besides the fundamental importance of Equation [1], it is probably advisable to emphasize the following:

$$\text{If volume factor} = \frac{k + r^{\frac{n-1}{n}}}{r} = m$$

then

Jet flow area varies as $\dfrac{1}{F}$

Actual jet energy varies as $(Fm)^2$

Actual flow velocity varies as (Fm).

The absolute results of the various quantities so represented by mere ratios can be readily obtained at any time, since all are referable to the initial conditions, thus:

$$\text{Energy (ft-lb. per lb.)} = \left(\frac{144n}{n-1}\right)P_1V_1\left(1 - k - r^{\frac{n-1}{n}}\right)$$

$$\text{Velocity (ft. per sec.)} = \left\{\left(\frac{288gn}{n-1}\right)P_1V_1\right\}^{1/2}\left(1 - k - r^{\frac{n-1}{n}}\right)^{1/2}$$

$$\text{Specific volume} = V_1\left(\frac{k + r^{\frac{n-1}{n}}}{r}\right)$$

From the forms of these it follows that the loss of energy per lb. is—

$$\frac{144n}{n-1}P_1V_1k$$

and this energy being dissipated in heat causes the specific volume to be

$$\frac{V_1}{r}k$$

in excess of what it would be theoretically.

These considerations show that if by experiment or otherwise the jet function is established for any point on the jet by means of relation (2) then, by means of experimental values of r and Equation [3], it becomes possible to determine the velocity and volume conditions at the point considered, and the total expansion loss that has accrued up to that point.

Strictly speaking, k is a reheating effect rather than a loss effect, but under the conditions of single-nozzle testing the difference between these is entirely negligible and need not be considered. Consequently the terms reheat and loss are used indiscriminately in specifying the quantity that k represents.

In addition to this, the authors show how various coefficients employed in nozzle work may be obtained from the general expression. This applies in particular to the coefficient of discharge and coefficient of velocity.

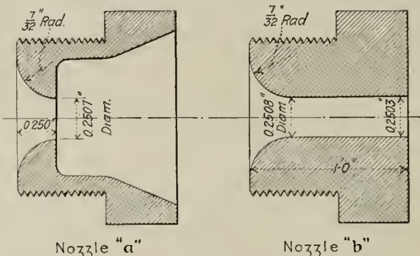

FIG. 3 CONVERGENT-NOZZLE FORMS

In the actual tests two convergent nozzles were used and the main tests were carried on with initial pressure of 75 lb. per sq. in. abs. and initial temperature of 560 deg. fahr. (An initial temperature of 400 deg. fahr. was also used in some tests, but the difference in the results for the two conditions proved to be very small.)

The two nozzles are shown in Fig. 3. Table 1 gives the various data; the function values included are for definite flow areas only, that is, for plane cross-sections in the parallel regions. The definite sets of figures in each case are obtained by variation of the back pressure, and the flow and function values are therefore obtained in terms of the pressure ratio of operation of the nozzle.

TABLE 1 DATA ON TESTS OF TWO FORMS OF CONVERGENT NOZZLES

Nozzle	Initial pressure, lb. per sq. in. (abs.)	Initial temperature, deg. fahr.	Steam flow, lb.	Duration of test, sec.	Nozzle pressure ratio[1]	Values of F at throat	Values of F at outlet
Simple Convergent Nozzle (a)	76.0	559	46	1301	0.580	....	0.2193
	76.0	565	46	1304	0.574	....	0.2195
	76.0	568	46	1314	0.593	....	0.2181
	76.0	569	43	1311	0.710	....	0.2044
	76.0	567	35	1321	0.834	...	0.1650
Convergent Parallel Nozzle (b)	76.4	558	59	1742	0.498	0.2088	0.2100
	76.4	566	49	1460	0.495	0.2077	0.2088
	76.4	565	45	1355	0.582	0.2055	0.2066
	76.4	565	40	1301	0.717	0.1903	0.1914
	76.4	567	33	1349	0.852	0.1515	0.1524

[1] Outlet pressure divided by initial pressure.

In conjunction with these, fall-of-pressure curves have been obtained for each condition. The expansion curves are very smooth lines and no material pressure fluctuations within the

place without loss.

The authors point out that the experimental points in Fig. 4 lie on quite a smooth curve. They also find it is allowable to omit from further consideration the two and three sets in each case, and that in order to cover the full range of action dealt with experimentally, it is sufficient to consider only the case represented by the points marked (*i*), (*ii*) and (*iii*) on each flow curve.

The three different outlet conditions for each nozzle may now be assumed as being completely established, and the probable internal conditions for any and all of these cases may be considered. This, however, is not quite as simple as it looks.

Thus, if we consider nozzle *a*, the problem takes the form of a determination of the F curves which represent the internal conditions along the jet. Again, Equation [2] gives F as a function of A, and if A could be calculated at various points from the nozzle sectional areas the problem would be simple. The authors show, however, that this cannot be done, because where the temperature is changing rapidly the pressure is not uniform over a plane cross-section and the area for any given pressure is not the same. The best way to obtain the correct forms of the F curves is by trial and error, using a rather complicated equation which the author gives as a check. It was in this way that the three curves shown in Fig. 4 for nozzle *a* were obtained. These curves are not continued beyond a ratio of 0.9. They seem, however, to be converging together and are very close to the theoretical. The above method of derivation is not employed to carry the curves further, because the method ceases to be at all sensitive when transition is made from the steep portions of the pressure-ratio curves to the flat top parts.

As regards the convergent parallel nozzle *b*, it is found that when throat values are plotted each practically lies on the corresponding F curve of nozzle *a*, which would tend to confirm the correctness of these curves.

On the whole, the F curve in Fig. 4 may be used for the purpose of determining the forms of the loss curves throughout the various expansion ranges, but in passing from the F values to the loss which these values denote, it becomes necessary to bear in mind that the resultant figures are affected by experimental errors. While these errors are small in so far as their effect on the F values is concerned, this is not so in reference to the difference between theoretical and actual F figures, and it is on these differences that the losses depend.

The losses for different r values can be determined from the F curves of Fig. 4 by means of Equation [3], and the work may be facilitated by employing calculating charts based on that equation.

The authors discuss in detail the subject of the boundary loss and the convergent loss and come to the following general conclusions:

The losses in a nozzle are referred to by a factor k which, in continued product with the initial pressure and volume conditions, gives the energy loss per pound. If this factor is strictly constant for any given ratio of expansion, independent of supply conditions, then the flow per square inch of area is accurately proportional to:

$$\left(\frac{P_1}{V_1}\right)^{1/2}$$

Any dependence of k on P_1 and V_1 upsets this proportionality, but the discrepancy will be the smaller if only a portion of the total k is thus affected. General experimental work shows that mass flow is closely proportional to the above factor, but not exactly so, the disagreement being of much the same order as experimental error.

It has been shown that in the expansion of a fluid through a nozzle there are at least two distinct types of loss. One, an effect of friction, seems demonstrated with fair conclusiveness; the other is apparently an inherent feature of the convergent portion of the expansion.

hydraulic mean depth and of a speed factor that varies only with the ratio of expansion. The constant involved will, of course, cover the influence of the surface finish.

This boundary loss may conveniently be considered as due to a scattering of flowing molecules resulting from impingement on the irregularities of the surface, with consequent retransformation of their flow motion into heat motion.

The second type, called the convergence loss, is caused by the rapid convergence in the entrance. It is shown that this effect is too great to arise from the work done against the deformative stresses created by viscous action; and it is indicated that the cause probably lies in effectual mass motions within the streaming body of fluid. The loss factor is shown to be largely dependent

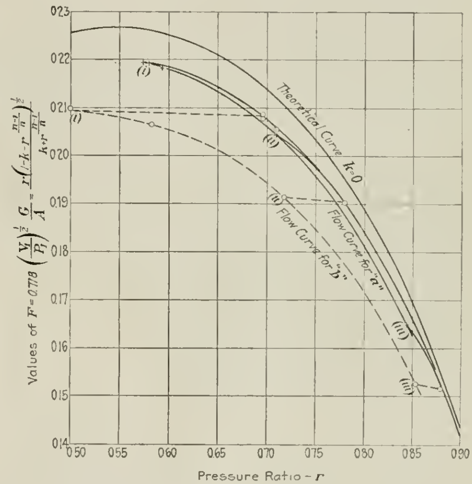

Fig. 4 F Curves

on the velocity developed in the convergent portion of the jet, but it must also be influenced by the actual nozzle form; and therefore any expression given the loss must contain some function of the convergence. Since with a fixed convergence the velocity is primarily important, the loss is affected by initial conditions of supply, and therefore departure from the practial rule that flow is proportional to the square root of P_1/V_1 must be expected. This departure will be the greater in those cases where this particular loss is a large proportion of the whole, e.g., in the purely convergent types, and this is in rough agreement with the experimental evidence available.

This convergence loss is then attributable to the establishment of molar currents in the main stream by and in the convergence. The damping out of these as the jet narrows to a straight path would cause a reheating effect by retransformation of kinetic energy.

It will be seen that the separation of frictional and convergence effects gives at once, through their different natures, a definite reason why the nozzle coefficients should fall as the expansion range is narrowed. The latter effect, measured per pound, is not reduced so rapidly as the available energy, and therefore has an increasingly important influence as the pressure ratio of action rises.

The rate of fall of the coefficient, whether of discharge or velocity, will depend on the relative magnitudes of the two losses. With any convergent type having a fixed inlet form the fall should be

less rapid as the straight tail length is increased, owing to the ready manner in which the frictional effects acquire a dominant influence. With nozzles of equal tail length, however, the more objectionable convergence will cause the more rapid fall. Thus, considering the convergent types used in actual turbine work, the forms at inlet are such as would compel belief that their convergence loss is more severe than that of the simple circular straight types, since there is rectangular formation, curvature of axis, and distinct differences in curvature between the two pairs of opposite sides. In this connection it is significant that the very scanty data obtainable on practical nozzles confirm this finding, the curves derived by Christlein, for instance, having an extremely rapid fall.

Again, the size of the nozzle would presumably have an influence on this loss, as the disturbing currents might then be supposed to be more extensive. If so, the slope downward of the coefficient curves would be more noticeable for the larger nozzles. There are practically no large-scale steam experiments, but reference to Fig. 1 will show that Professor Gibson's curve for air displays this feature. Now these experiments were made with diameters of the order of $1^1/_2$ in., that is, several times the size of experimental steam nozzles, and it would therefore seem that there is a definite dimensional influence.

The effect of dimensions on the convergence loss will be opposite to that on the boundary loss. It must be clearly in view that the frictional occurrences are apparently inversely dependent on the hydraulic mean depth, and therefore small-scale experiments are most suitable for the examination of these. Thus, in the authors' experiments the introduction of an $^1/_8$-in. diameter search tube into a $^1/_4$-in. bore nozzle increases the surface by 50 per cent and reduces the flow by 25 per cent, i. e., the search tube doubles the effect and therefore makes it the more readily determinate. For the same reason efficiencies obtained from such small nozzles are not directly applicable to larger sizes, and therefore to say that the experiments are faulty because in practice better values are apparently shown, is no sound charge. Application to the practical forms can only rationally be made when the constant factors in the different loss effects are known.

It may be taken, then, that the total loss to any point x along the jet within the boundary form is given by—

$$k_t = a_1 \int_o^x (Fm)^2 \frac{l}{A}\, dx + a_2(P_1V_1)^{\frac{1}{2}} \int_o^x \left\{ f(c, x) \frac{d}{dx} (Fm) \right\} dx \quad \text{. . [26]}$$

This expression is too involved to be of much practical value, but considerable simplification is possible with only moderate loss of accuracy. It may be permitted to charge the frictional loss against the tail piece only, and relate this to the average velocity factor therein; while the entrance loss may be made directly dependent on the speed established in the convergence, thus:

$$k = a \times \frac{L}{\eta} (Fm)_0^2 + b(P_1V_1)^{\frac{1}{2}} (Fm)_c \quad \text{. . . . . [27]}$$

where a = constant for surface
L = length of parallel portion
h = hydraulic mean depth of parallel portion
$(Fm)_c$ = velocity factor at end of convergence.

Although (Fm) contains k as a term, the influence of this is not great and (Fm) might be taken as equal to the theoretical—

$$\left(1 - r^{\frac{n-1}{n}}\right)^{\frac{1}{2}}$$

Actually, however, it will be found that by using a suitable chart for calculation rather closer approximations to the real values can be obtained.

Taking the actual nozzles used, the constants are of the following order: $a = 0.0055$; $b = 0.0005$. The constant a is for a moderately well-finished bored-out brass nozzle, while b covers the convergence effect for a small nozzle having a straight axis and a radius of entry nearly equal to the diameter.

For practical application further experimental investigations seem necessary, and a few final remarks on the best forms for these might be given.

The boundary loss will be most readily obtained from examination of the action in straight parallel lengths. The value of the jet function F is constant along such a path, and the growth of loss is closely represented by a straight line. For these reasons pressure readings are only necessary at entrance to and outlet from the parallel portion. Again, this frictional loss is most clearly shown by flow experiments on small-size nozzles.

Consequently for the determination of frictional constants a few long parallel nozzles—of small bore and having different surfaces—might be used; provision also being made for the observation of at least two pressure values.

Examination of the convergence loss requires determination of the conditions in a clearly defined area at the termination of the entry curve. Any chosen convergence must then be fitted with a very short parallel outlet; although with the more awkward form rather greater lengths might be necessary to insure fairly stabilized conditions. There are effects both of curvature and size, and it is probable that experiments with air flow might give a more ready means of examination.

For the convergence effects, then, a few standardized entrance forms might be used—each with short parallel outlet—each form, say, in triplicate, differing only in linear dimensions. Mass-flow determination accompanying pressure reading at outlet would then allow of establishment of the general variation of this loss, and any odd form that might be used at times in practice could be reasonably covered by interpolation from the known standard results. AIR MACHINERY

Pressure Regulation in Air Receiver or Line—Operating Air Compressors in Parallel

The Automatic Regulation of Air Compressors, Robert Nitzschmann. In compressor operation it is usually necessary to maintain a constant air pressure. In some cases, particularly with small and medium-size units, hand regulation is employed for governing the delivery air pressure either by varying the amount

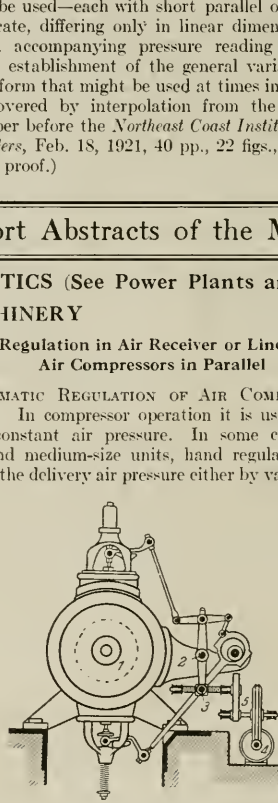

Fig. 1 Device for Automatically Regulating Air Pressure of an Air Compressor

of inlet air (throttling regulation) or by operating directly on the steam supply to the driving prime mover. For larger installations automatic regulation is necessary, which again may be of two kinds; namely, operating by the air pressure directly, or through some kind of a servo-motor.

In the present article a device is described which makes it possible to regulate the air-compressor output not only from the pressure at the compressor directly but also in accordance with the pressure with air lines fed by the compressor.

Fig. 1 shows the governing device as applied to a steam-driven air compressor. Here, 1 is the steam cylinder; 2, the valve-gear shaft; 3, the lever of the valve-gear shaft with the crosshead;

4, an electric motor; and 5, an intermediary element between the electric motor 4 and the lever 3.

The operation of the device is as follows: When the air pressure in the receiver varies, an appropriate relay (Fig. 2) sets the motor 4 in motion in such a way that, for example, the motor 4 rotates the shaft 2 of the valve gear governing the steam admission to cylinder so that the admission decreases, which results in a corresponding decrease in the speed of operation of the compressor. This variation of admission lasts until the desired pressure is reestablished in the receiver. In the case of falling off of pressure in the receiver, a similar operation takes place but in the reverse sense.

Fig. 2 shows the arrangement of the pressure relay employed with a polyphase servo-motor. According to the position occupied by piston 1 of the relay, the contact arms 2, 3 and 4 press against either the contacts 5, 6 and 7(pressure too high and the motor

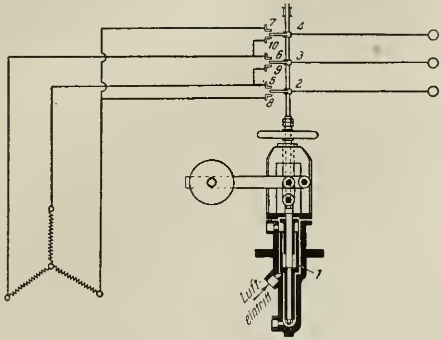

Fig. 2 Electrical Relay Employed with the Device Shown in Fig. 1
(*Lufteintritt* = Air Inlet)

decreases admission of steam to the steam cylinder) or contacts 8, 9 and 10 (pressure too low in the receiver and more steam is caused to flow into the steam cylinder).

Where an extensive system of piping and machinery has to be supplied with compressed air, especially from several air compressors located at different points, it is often important that a certain predetermined amount of air be supplied at a constant

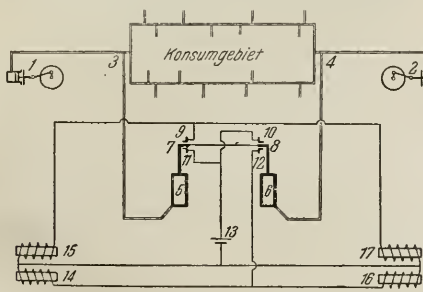

Fig. 3 Device Shown in Figs. 1 and 2 Applied to a System Employing two or More Compressors
(*Konsumgebiet* = Piping and Machinery Fed from the Compressors)

pressure. Fig. 3 shows the connections to the regulating motors to cover such a case.

In this figure 1 and 2 are two air compressors located at different points; 3 and 4 are the points at both ends of the system supplied by compressed air at which the given pressure is maintained; 5 and 6 are the pressure relays belonging respectively to 3 and 4 with pistons carrying the electric contact arms 7 and 8; 9, 10, 11 and 12 are respectively the stationary contacts of the pressure relays; 13 is a source of electric current; and finally 14, 15, 16 and 17 are the electric relays operating the servo-motors located respectively at each of the compressors 1 and 2 and governing the admission of steam to the steam cylinders in the manner described.

With this system of governing, the operation is as follows: If, for example, at the point 3 of the piping system fed by the compressors, the air pressure becomes excessive, the movable contact 7 is forced against the stationary contact 9. The two motors 1 and 2 at the compressors remain idle and the equalization of pressure takes place right in the piping system without calling on the automatic regulation. It is only when the pressure at 4 also exceeds the desired limit that the circuit is closed, the electric relays 15 and 17 are energized, and the steam supplied to the engines driving the compressors 1 and 2 is simultaneously reduced. The regulation is similar when the air pressure in the line falls below the desired limit.

With appropriate variations the same method of regulation may be applied to rotary compressors and may be used to govern the compressor output instead of the receiver pressure. (*Feuerungstechnik*, vol. 9, no. 9, Feb. 1, 1921, pp. 74–75, 3 figs., *d*)

FUELS AND FIRING

What Determines the Clinkering Ability of Ash ?

Constituents in Ash that Cause It to Fuse, G. A. DeGraaf. The discussion applies in particular to bituminous coal. Among other things, the author shows that sulphur in bituminous coal occurs mainly in the form of iron pyrites, which, when burned

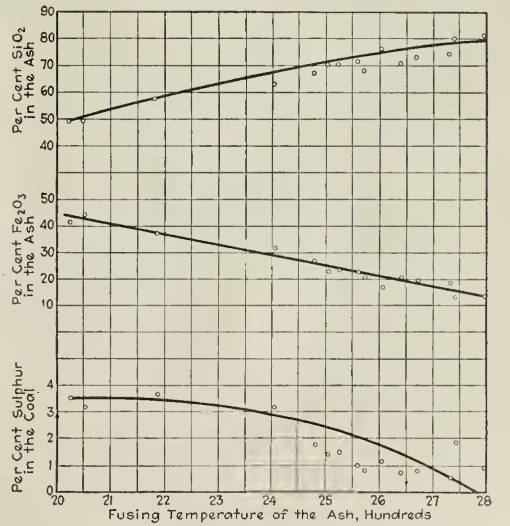

Fig. 4 Curves Showing Relation of Fusing Temperature of Ash to Percentage Content of Silica, Iron Oxide and Sulphur

with the coal in the fuel bed, forms iron oxide; a material which by itself would not produce clinkers. If, however, this iron oxide is exposed to high temperatures in the presence of silica and silicates usually also available in the ash, clinker in the form of fusible silicates may be produced.

It is temperature of the grate and of the fuel bed near the grate that determines whether a certain coal will form troublesome clinker or no clinker at all. Because of this, it is important to keep the grate and the part of the ash bed near it at as low a temperature as possible during operation.

On the other hand, however, if coal contains pyrites in large lumps they may fuse before they are completely burned and start the formation of clinkers. The conclusion to which the author comes is, therefore, that although high sulphur content may increase the possibility of clinker formation, it is not a definite indication that clinkers will be produced, as the action depends upon the form in which the sulphur is present.

The author calls attention to the fact that the complexity of the content of the ash makes it difficult to draw a conclusion as to its tendency to form clinker. Fusibility of ash depends apparently upon the ratio of the silica to the iron, aluminum, calcium, etc., present. As a rule, ash high in silica contains little iron and will not fuse easily, but if the silica decreases and the iron increases, fusing will take place at a lower temperature. The author does not believe that a definite relation between the clinkering properties of coal and the chemical composition of well-mixed ash can be found, especially as in addition to the chemical analysis there are many other factors which influence clinkering, such as the construction of the furnace, combustion space, draft, cooling of the grates, etc., as well as the methods of firing.

Fig. 4 is of interest as giving an idea of the relation of fusing temperature of ash to the percentages of silica, iron oxide and sulphur.

The author explains the methods of carrying out fusibility tests of ash and in particular the use of Seger cones. (*Coal Age*, vol. 19, no. 12, pp. 534–539, 5 figs., *pe*)

LUBRICATION (See also Power Plants)

Tests on Lubrication with Emulsified Oils

LUBRICATION OF STEAM CYLINDERS WITH OIL EMULSIONS, Dr. Eng. Hilliger. Data of tests bearing on performance and consumption of lubricant by steam engines lubricated with plain oil and oil emulsions, carried out at the Salbke Works of the R. Wolf Company, Magdeburg, Germany, on a 25-hp. non-condensing locomobile engine.

In the course of these tests either plain oil or an emulsion of oil with saturated lime water was used, the lime water having a content of 1.2 grams (18.4 grains) of lime per liter (0.26 gal.) of distilled water.

The plain oils, which were all of mineral origin, had viscosities (Engler, at 50 deg. cent.) varying from 33.6 to 39.4. The content of lime water was in excess of 40 per cent but below 50 per cent.

The steam cylinder of the locomobile engine was provided with pressure lubrication of the usual type feeding 16 grams (246 grains) of oil per hour. The engine gear was abundantly lubricated in order to reduce friction losses as far as possible. Previous tests have shown that the usual indicator method of measuring cylinder performance was not sensitive enough for the present purpose and the governor was so set that at each revolution the amount of steam flowing into the cylinder was dependent exclusively on the boiler pressure. The relation between the boiler pressure and the average indicated pressure was derived through very careful indicating of the various steam pressures and was repeatedly tested during the course of the experiment.

It was found that for an operating pressure of 12 atmos. the mean indicated pressure was 5.06 atmos. with saturated and 4.93 atmos. with superheated steam. In the course of the tests the boiler pressure was maintained constant and the load varied by means of a resistance formed by a bank of incandescent lamps.

Method of Testing. In order to compare the lubricating ability of various oils, it is necessary to produce in the cylinder a very thin oil film, such that its wear may be observed through an increase in the energy consumed by friction. The better the lubricant the better it will adhere to the rubbing surface and the longer it will withstand the wear produced by the friction of the rubbing parts. In order to produce a sufficiently thin film of oil, the lubrication was begun in each test by supplying the usual amount of lubricant to the cylinder and then cutting it off entirely. During the period when the lubricant is supplied at the usual rate, a film of oil is built up on the inner walls of the steam cylinder. At the same time small quantities of oil collect in the piston rings and in several other dead spaces in the cylinder. When the supply of lubricant is discontinued, the film on the cylinder walls is at first maintained by supplies from these small oil reserves and its distribution from them depends on the quality of the oil. Gradually, however, the oil film is worn away by the rubbing of the parts, which causes a falling off of mechanical efficiency, which may be represented in the form of an efficiency curve. The length of the period that this decline of mechanical efficiency continues is an indication of the ability of the oil to adhere to the walls, and also of the ability of the oil to act as a lubricant even when present on the walls of an engine cylinder only in films of exceeding thinness.

In this way the lubricating qualities of the oil and its economy of consumption may be expressed in comparable figures. The economy of consumption of oils may also be determined from their minimum consumption, which means the amount of oil at which the mechanical efficiency of an engine attains its maximum value and is not improved by further additions of oil. Tests along these lines have been carried out in addition to the tests referred to above. When the supplies of oil in the cylinder were

exhausted, a predetermined amount was forced into the cylinder and the resulting increase of efficiency determined. These tests also served to prove that the decrease in efficiency found from the previous tests was due exclusively to the gradually decreasing amount of lubricant supplied to the cylinders. If a given amount of oil forced into the cylinder was found insufficient to bring the mechanical efficiency of the engine to its original value, the amount was gradually increased until this took place. The amount of oil finally delivered which resulted in the efficiency of the engine being brought back to its original value, was the minimum amount necessary for a regular operation of the engine. In all experiments the engine cylinder at the beginning of the test was carefully washed out with a mixture of some other lubricant with gasoline.

Data of Tests. Figs. 5 and 6 show efficiency curves of an oil and an emulsion with saturated and moderately superheated steam. From this it would appear that the emulsion is a much better lubricant than the plain oil, especially at moderate superheat. [By moderate superheating is meant such that the steam temperature is 330 deg. cent. (626 deg. fahr.), while at high superheat it is 430 deg. cent. (806 deg. fahr.).]

made therefrom, not only at moderate but also at the higher superheats.

From the results obtained in these tests it would follow generally that emulsions are better lubricants than the oils from which they are made, and that they maintain their lubricating properties longer when working with higher superheats. In order to bring this out more clearly Figs. 7 and 8 have been plotted, where the curves represent data of tests with an oil and an emulsion (different from those with which the tests in the two previous figures were made) with saturated, moderately superheated, and highly superheated steam. From these figures it would appear that the tests with oils produce quite divergent results, while the efficiency curves from the tests with emulsions lie very close together. From this it may be concluded that the lubricating properties of the emulsion are much less affected by the increase in the degree of superheat than those of plain oil.

In order to facilitate the comprehension of the data collected in the course of these tests, the author employs a characteristic number for denoting the variation in efficiency instead of an efficiency curve, namely, the time in minutes during which a falling off of 1 per cent takes place in the mechanical efficiency. Such numbers which may be used for comparing various lubricants are derived directly from the curves and are presented in Table 1 for saturated, moderately superheated, and highly superheated steam. From this table, again, it is readily seen that the lubricating values of the emulsions are much higher than those of the original oils from which the lubricants were made. It also appears

TABLE 1 TIME IN MINUTES DURING WHICH EFFICIENCY DECREASES BY 1 PER CENT

Oil No.	Saturated Steam Oil	Saturated Steam Emulsion	Moderately Superheated Steam Oil	Moderately Superheated Steam Emulsion	Highly Superheated Steam Oil	Highly Superheated Steam Emulsion
1	31	55	9	37	...	15
2	70	112	38	85	31	65
3	..	...	...	...	84	150
4	..	...	193	250	178	225

clearly that high superheat affects oils more than emulsions containing them.

As regards the comparative consumption of oils and emulsions, it would naturally be expected that this would depend on the lubricating ability of the material. In all tests the oil feed was found to be sufficient for operating the engine in the usual manner. Data of the tests having for their purpose the determination of the minimum sufficient amount of oil are presented in Table 2. Where the plus sign is affixed to a value it shows that the amount given would have to be slightly increased in the regular operation of the engine. From this table it would appear that emulsions are much more economical than the oils from which they are made.

TABLE 2 MINIMUM SUFFICIENT CONSUMPTION OF LUBRICANT IN GRAMS PER HOUR

Oil No.	Saturated Steam Oil	Saturated Steam Emulsion	Moderately Superheated Steam Oil	Moderately Superheated Steam Emulsion	Highly Superheated Steam Oil	Highly Superheated Steam Emulsion
1	16	8	16+	8	....	16+
2	8+	8	8+	8	16+	16
3	....	..	....	..	16	16
4	....	..	16	8	16	16

The number of tests, however, was not large enough to furnish data sufficient to express numerically the degree of economy presented by the emulsions. (*Zeitschrift des Vereines deutscher Ingenieure*, vol. 65, no. 10, Mar. 5, 1921, pp. 248–249, 5 figs., *eA*)

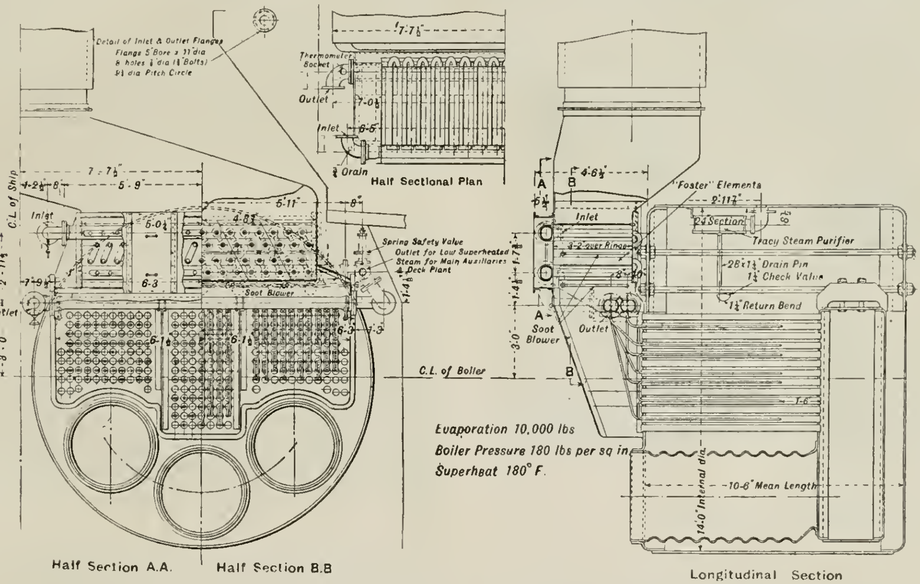

Fig. 9 Foster Double-Stage Superheater Applied to Cylindrical Marine Boiler

MACHINE SHOP (See Special Tools)

MARINE ENGINEERING

A Superheater Giving Steam of Two Different Degrees of Superheat

Foster Double-Stage Superheater. Description of a combined flue-type and smoke-tube superheater giving a superheated steam to marine engines and low-superheated steam to auxiliaries, manufactured by a British company.

In the ordinary flue-type superheater the ends of the tubes nearest the combustion chamber are very liable to corrode through, which is said to be due mainly to the impinging at high velocity of the small particles of moisture which pass from the stop valve into the superheater elements. The risk of failure from this cause is somewhat reduced by the usual thickening of the tube ends, but it rather increases danger on account of the high temperature reached by the superheater elements at the bend necessary to provide the desired steam temperature inside the tubes.

The Foster double-stage superheater, Fig. 9, has a number of waste-heat elements arranged in the uptake into which the steam

from the boiler in led, as a result of which it passes into the flue elements absolutely dry and at a temperature about 60 deg. fahr. above saturation point. In addition to this, the steam as it leaves the boiler is passed through a Tracy purifier where it is freed from the impurities which otherwise would be deposited on the interior surface of the superheater.

From the waste-heat elements the steam is led to the main headers in front of the boiler leading to the flue-tube superheater elements, but before reaching the headers the steam passes through a pipe fitted with a spring-loaded safety valve and a stop valve from which steam for the main auxiliaries and the deck machinery can be drawn. This enables these engines to work economically with low-temperature superheated steam and without the disadvantages which are found to accompany a high degree of superheat.

As the steam entering the headers already contains approximately 60 deg. fahr. of superheat, the number of superheater elements is smaller, and the elements instead of being brought practically to the combustion chamber are stopped at a distance of about 1 ft. 6 in. from the ends of the tubes, and hence the tubes are not subjected to the maximum temperature of the furnace gases.

In the Foster superheater the end of the superheater tube carries a standard $^3/_4$-in. type thread (Fig. 10). The steel nut carrying a

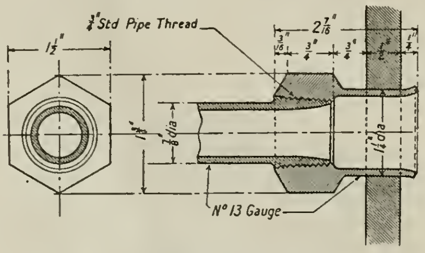

FIG. 10 CONNECTION OF SUPERHEATER ELEMENTS TO HEADERS IN A FOSTER SUPERHEATER

$1^1/_4$-in. diameter mouthpiece is expanded into the header. If the tube should fail, the mouthpiece can be readily removed in the usual way and only the nut will be damaged. (*Shipbuilding and Shipping Record*, vol. 17, no. 10, Mar. 10, 1921, pp. 285–286, 2 figs., *d*)

PAPER INDUSTRY (See Power)

PIPE

CENTRIFUGALLY CAST STEEL PIPE, George K. Burgess. Abstract of a report of tests carried out by the author in 1918 at the Bureau of Standards on samples from hollow steel cylinders made by the W. H. Millspaugh process.

No data as to the process itself are given, except that the cylinders were cast in a machine revolving about its horizontal axis. The cylinders are said to have walls from $^1/_2$ in. to $3^1/_2$ in. thick. The outer surfaces were fairly smooth but the interior surfaces were rough. Plain carbon- and nickel-steel cylinder castings were investigated in the condition as cast and after various heat treatments.

Results of the radial surveys for hardness and chemical analyses show there is a gradual increase in carbon from the outside to the inside surface for all castings. This increase ranges from 0.02 to 0.09 per cent and appears to be roughly proportional to the carbon content, so that the percentage in variation remains practically constant. The nickel and phosphorus appear to follow the carbon very closely in their behavior as to segregation; manganese and silicon, on the other hand, are nearly constant across the radial section, while sulphur, although somewhat erratic, in general is distributed similarly to carbon.

The hardness surveys follow closely the chemical segregation, the higher numbers occurring on the inside layers. Stresses across section of tubes were measured by cutting out rings, and it would appear that the internal stresses are of the order of the elastic limits of the material, the outer zone of the casting being in compression and the inside ring in tension.

Various attempts were made to improve these castings by heat treatment, the data of which are given in the form of tables. Most samples show good tensile strength for their composition and treatment, and there does not appear to be any marked difference in values for longitudinal and transverse specimens.

Certain of these treated steel castings would appear to compare favorably in their properties with those of forged material of the same composition. For example, the physical properties of some of the castings are equal to or better than ordnance requirements for gun forgings.

The only evidence of unsoundness of the metal was the presence of small blowholes in the inner zone, usually within $^1/_{16}$-in. of the surface.

The microstructure of some, at least, of these castings is better than that of ordinary castings; certain ones show pronounced ingotisms (dendritic structure). The nickel steels contain more slag inclusions than is usual in ordnance steel, showing that this centrifugal process may not clear up a basic steel. The ingotism and coarse-grained structures of these centrifugal castings can, in general, only be removed by prolonged and repeated heat treatments., i.e., normalizing followed by double quench and draw. (*The Iron Age*, vol. 107, no. 12, Mar. 24, 1921, pp. 764–766, 5 figs., *eA*. In this connection, attention is called to an editorial in the same issue, p. 789, discussing the centrifugal casting of steel as a metallurgical development which may become of importance.)

MANUFACTURE OF WROUGHT PIPE FOR HIGH PRESSURES. For hydraulic purposes very strong pipe is required because the high pressures of hydraulic lines exert enormous bursting forces and the potential energy of the water under such working pressures closely approaches that of the thrust of a steel rod working as a piston under similar pressure.

The pipe must therefore be made with unusual care, and furthermore, to be efficient in the face of the friction developed by fluid flowing under enormous pressures and high velocities, the pipe must be clean and smooth and must be capable of bending without excessive distortion of the internal diameter. These conditions require that the pipe be welded and rolled according to the best mill practice, and from metal possessing the usual combination of high tensile strength and great ductility. The practice described below is that followed by the National Tube Company, Pittsburgh, Pa.

To make pipe for hydraulic purposes the solid ingot is rolled down to plates of the required dimensions, which eliminates laminations occurring in plates rolled from built-up bars and insures homogeneity of the pipe wall. Defects such as blisters or blowholes are obviated in the skelp from which pipe is made by a mechanical process of working the metal in bloom form known as "Spellerizing." It is a kneading process which consists of subjecting the heated bloom to the action of rolls having regularly shaped projections on their working surfaces.

High-pressure pipe of smaller sizes is manufactured by the butt-welding process. The hot plate is welded into pipe at a point close to the end of the furnace by drawing it through a die shaped like a bell with a hole in one end. The pipe is reheated several times and drawn through dies having gradually decreasing diameters until the proper size is obtained. This is done in order to weld thoroughly the very thick abutting edges of the seam and to provide the necessary strength at this point. When pipe is not intended for high-pressure service, it is drawn through only one or two dies.

The larger sizes of pipe for high-pressure purposes are made by a process in which the edges of the plate are overlapped by the seam. The plates are properly rolled, heated and bent into rough tubes (skelp), and are then charged into a furnace where they are heated to a welding temperature. From the furnace they go into the revolving rolls of the welding apparatus, so grooved that they form a circular opening between them of approximately the same

size as the outside diameter of the pipe. In this opening is a bullet-shaped mandrel, and as a skelp comes from the furnace it is caught by the rolls which force it forward over the mandrel and press the overlapping edges together into a sound weld.

To make one length of the strong pipe used for certain purposes, two lengths of pipe are welded in this manner and then telescoped, this being arranged in such a way that the welds of the telescoped pipes are at diametrically opposite points. In this position they are reheated to a welding temperature and are both passed at once through the welding rolls, thus forging them into a single length of heavy-walled pipe.

After the pipe has been welded it is passed through rolls which give it the required outside diameter, and through cross-rolls to straighten it and give it its true circular shape. The pipe is then slowly cooled on a continuously traveling table, after which the tags and the ends which have become damaged in manufacturing are trimmed off and the pipe is subjected to a hydraulic test to prove the soundness of wall and weld. The test pressures vary from 700 to 3000 lb. per sq. in. according to pipe size and type of weld.

Hydraulic pipe is made in nominal sizes of 9, 10, 11, and 12 in., and is tested with hydraulic pressures of from 1200 to 1800 lb. per sq. in., depending upon the size and upon the wall thickness. Each of these sizes is made in four different thicknesses and weights.

Making wrought pipe for high pressures is extremely exacting work, and such is the necessity of keeping the closest possible control on all the materials going into its manufacture that, e.g., at the plant of the National Tube Company—the largest manufacturers of this pipe in the country—everything from the ore to the finished product is made in the plant. (*Machinery*, vol. 27, no. 8, Apr. 1921, pp. 755–756, 5 figs., *d*)

POWER

Gear Drives in British Textile Mills

The Individual Gear Drive for Heavy Looms, G. F. Sills. Plenty of evidence is available in British practice to uphold the advantages claimed for the individual gear drive. As an instance, it is stated that the largest electrical individually driven weaving shed in the country up to the time of the armistice had 1162 plain, narrow-reed-space Lancashire-type looms individually belt-driven, each with its own motor. When a large extension was contemplated the owners went into the matter carefully and finally ordered a further 570 individually driven units equipped with a more expensive gear drive, in spite of the fact that the looms were of a

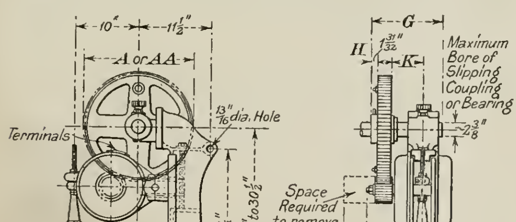

Fig. 11 Standard Loom Motor with Gear Drive ($^3/_4$ to $1^1/_4$ Hp.)

relatively cheap type and were weaving an article which did not command a high market price.

Fig. 11 shows a view of the latest electrical individual gear drive suitable for equipment up to $1^1/_4$ hp., made by the English Electric Company. (A number of similar equipments of only $^1/_2$ hp. have been supplied to the textile trade.)

This form of gear drive is claimed to be better built than was the case formerly. The pedestal section is stiffer and the pedestal casting is so arranged as to give heights of centers from the floor varying between $26^1/_2$ in. and $30^1/_2$ in. This means that the pedestal casting would be the same for the horsepower range from $^3/_4$ hp. to $1^1/_2$ hp.

Other improvements are the stiffer conical pin which holds the motor clamp in position, and an eyebolt which is supplied to fit on to this pin for carrying the stiffening rod back to the loom frame. A boss is also provided on the pedestal for carrying a second stiffening rod to the loom frame. The centers of the holding-down foundation bolts are the same as those on the old-type pedestal, thus allowing the new-type pedestal to replace the old-type without any considerable amount of alteration. This pedestal is also designed to allow of a loom crankshaft speed of 76 r.p.m. This particular gear drive is suitable for the ordinary loom.

Where the power required is over $1^1/_2$ hp. a much more substantial form of drive is used than that shown in Fig. 11. In this type the motor is not supported centrally, but has special end shields which are clamped to two side supports coming up from the pedestal. This has the advantage of transmitting shocks and power from the pinion to the ball bearings, thence to the end shields, and finally to the pedestal without in any way straining the stator of the motor.

In this extra heavy type of drive a slipping clutch is used for absorbing the shock of the motor pinion in the event of a "bang-

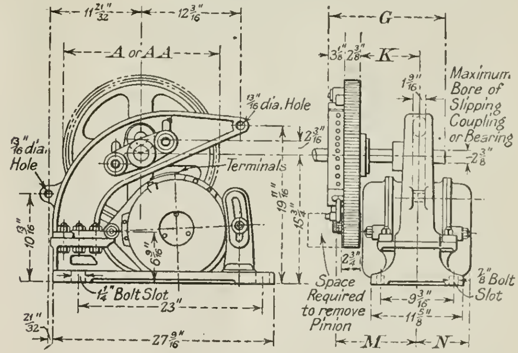

Fig. 12 Extra Heavy Individual Gear Drive for Looms with Low Centers

off," as there is considerable momentum stored in even a small motor rotor running at 965 r.p.m. The central cast-iron boss is a light force fit on the loom shaft to which it is keyed, and is also provided with three studs. The spur wheel is bored to be a loose revolving fit on a portion of the central boss, previously referred to, but is kept from turning on this by the spring bands which are adjustable for tension. At starting there should be no slip, and the correct setting is obtained by making a chalk line to cross the spur wheel and central boss with the loom stationary. The loom should be started up and stopped in the ordinary way, when the spur wheel and central boss should still be in the same relative position to one another. If there are any signs of slipping, which is clearly indicated by the chalk line just mentioned, the springs should be tightened until there is no movement. With this setting there should be a relative movement of from 1 in. to $1^1/_2$ in. on a "bang-off."

For looms with low centers (some as low as $15^3/_4$ in.) the drive shown in Fig. 12 is used. Loom motors are made specially for the purpose and are totally enclosed and equipped with ball bearings and grease lubrication requiring no attention for long periods. The starting torque of a loom motor is about $2^1/_2$ times that of the normal type. The temperature rise is only 35 deg. cent. as against 50 deg. cent. for the same type of commercial motor. (*The Electrician* (London), vol. 86, no. 2229, Feb. 4, 1921, pp. 150–153, 8 figs., *d*)

POWER GENERATION

Economic Features of Superpower Schemes

Industries and Superpower, Harold Goodwin, Jr. The cost of fuel and purchase of power for all the industries in the United States amounts to only about $2^1/_2$ per cent of the value of the products and is only about $4^1/_2$ per cent of the value of the materials going into these products. (These figures apply to the country at large and not to individual industries.) Nevertheless the subject of power generation and distribution is, of course, of the highest importance.

As regards the determination of the future load, Dr. George Otis Smith, Director of the U. S. Geological Survey, has pointed out that the steam engine has been the cause of centralization of industry, while electricity has already been the means of decentralization, and the greatest mission of the superpower system should be the aiding of industry in its economic decentralization.

Fig. 13 shows the method of determining the limit of saturation

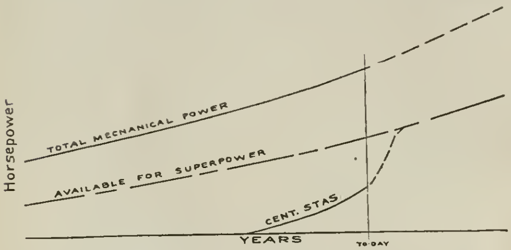

Fig. 13 Growth of Industrial Mechanical Power

of industries with power. The upper curve shows the growth of the total mechanical power and the growth which may be predicted for it in the future, while the next curve shows the proportion of the load which could be economically supplied by central-station service. The lower curve shows the growth of central-station power and the way its logarithmic extension would continue. It is evident that the limit of central-station supply of mechanical power should be reached if the present rate of growth is maintained for a few years, and that after the point of saturation has been reached the growth will be much more gradual.

This consideration would show that it is not safe to predict the load of the superpower system simply by the extension of the present growth curve of central stations.

The location of industries is determined by many factors, such as labor, transportation, raw-material supply, etc. In some cases there seems to be a tendency for industry to move to the nearest supply of labor; while in others plants have made arrangements for drawing labor to them instead of carrying the plant to the labor. Availability of power through the superpower scheme may be of assistance in facilitating the location of plants on sites otherwise desirable. If there is a tendency of industry to decentralize, availability of power will be one of the controlling factors in the building up of new industrial centers. (*The Journal of the Engineers' Club of Philadelphia*, vol. 38–2, no. 194, Feb. 1921, pp. 63–68, 5 figs., *g*)

Superpower Stations for Central Indiana, Frederick L. Ray. General outline of the needs, advantages and possibilities of a system of generating stations located in coal-mining districts and supplying the entire central part of the state. Credit for many of the ideas advanced is given to John A. Stevens, Mem. Am.Soc.M.E.

In this project primarily developed for central Indiana but which could be extended to cover practically all of Indiana and the eastern half of Illinois, it is intended to locate the power plant on the Wabash River because a project of this kind cannot be considered unless there is an abundance of water for condensing purposes, a condition which is fully satisfied by the Wabash River. The intention is to erect several plants of about 150,000 kw. capacity each in the coal field on the river between Terre Haute and Vincennes.

A table in the original article shows the approximate kilowatt-hours generated per month for some 25 cities of central Indiana, from which it appears that the total output is close to 45,000,000 kw-hr. per month produced at a cost of about 95,000 tons of coal, with a consumption of coal per kw-hr. varying from 3.20 to as high as 9.66 lb. and averaging about 4.5 lb. per kw-hr.

This current could be generated in a modern plant for 2.12 lb. of coal per kw-hr., including 30 per cent transmission losses up to the consumer, which would mean a saving estimated at more than 48,000 tons of coal per month, equivalent to a saving per year of approximately 600,000 tons.

The general outline of the design of the plant is given. It is intended to make provision on each boiler for the burning of powdered coal to the extent of 50 to 200 per cent of the normal demands. Then in an emergency it would be possible to increase the output to 400 per cent without crowding the stoker. The mixture of the flame from the powdered coal with that of the flame from coal and stoker would greatly improve combustion, and the trouble of ash removal with powdered-coal burning would be eliminated, for the ashes from the powdered coal would fall upon the ash and refuse from the stoker and could be readily dumped to ash pit and removed.

The railroads in this district should be electrified as quickly as possible, but not until all other industries have been taken care of. (Paper read before the Indiana Engineering Society, abstracted through *Power Plant Engineering*, vol. 25, no. 5, pp. 262–264, 1 map, *g*)

Superpower Zone in Canada, Robt. G. Skerrett. The author claims that Canada has set the pace for the United States in the creation of what may properly be termed a superpower zone, referring to the work of the Ontario Hydroelectric Power Commission.

Ontario, which is one of the most densely populated sections of the Dominion, is practically devoid of its own sources of fuel but has a large potential supply of water power. It was to develop this that the Commission was created in 1906. (Its powers and organization have been since modified by a number of subsequent acts of the Canadian Parliament.)

At the beginning, the main attention of the Commission was devoted to the development of the Niagara project. Later on, however, eleven other districts were covered and last year the transmitting wires distributed more than 315,000 hp., while it is expected that by the close of 1921 the total output for public use will amount to 750,000 hp. and will be approximately doubled in the next two years.

The charges for electric energy are such as to cover the expense of the service and create a sinking fund which in 30 or 40 years will leave each constituent community the owner of its plant.

Generally speaking, 1 hp. raised by steam entails an outlay in Canada today of from \$40 to \$60 annually, whereas the Commission is able to sell a hydroelectric horsepower for only \$18 for a twelvemonth.

An interesting feature of the rate-making system of the Commission is found in the fact that in each community the small user pays for energy the same price as the large consumer, and the rate in each locality is determined on its individual merits. The dominating purpose of the Commission is that there shall be an equality of right to power in all areas within range of the current generated in any of its plants.

In the early days the Commission bought all its supplies from dealers. Now, however, with its expanded organization, it buys lamps and other equipment in large quantities direct from manufacturers, giving the consumer the benefit of the cheaper price.

The installations owned by the Commission (not including franchise valuations) represent a cash value of close to \$57,000,000. The Niagara power development cost \$15,000,000 and the combined valuation of the Commission is well in excess of \$100,000,000. (*Scientific American*, vol. 124, no. 13, Mar. 26, 1921, pp. 246 and 258, 1 map, *d*)

POWER-PLANT ENGINEERING (See also Lubrication and Marine Engineering)

Canals as Sources of Condenser Water for Large Plants

The Cooling of Water in a Canal, L. C. Kemp. Description of a recent series of experiments carried out in England, and of interest because of a number of large power stations which are being erected on canal sites.

The Lero Road power station of the city of Leicester is situated on the banks of a canal, upon which it relies entirely for the cooling of circulating water for the condensers. It has approximately 9500 kw. of plant installed, comprising a turbine and reciprocating machinery supplied from different circulating systems. The inlet and outlet circulating-water ducts are separated by less than 200 yd. but sufficient cooling is available to operate the station satisfactorily.

The tests were carried out primarily to determine in a qualitative sense the conditions assisting the dispersal of heat in the canal, and also to establish, if possible, heat-gradient charts and an approximate dispersal factor which would be of value as a basis in determining the probable performance of proposed new power stations for similar sites. In the tests the following quantities were determined:

The heat quantity entering the canal from various sources.
Temperature of the canal surface in the area affected by the heat currents.
Atmospheric conditions.
Heat carried away through the lock.
Heat stored or released from the bulk of the water quantity affected, due to difference in average temperature before and after the test.
Cooling effect of cold river water entering the system to provide make-up for the water evaporated.

During the test the temperature of water showed a net increase at all points, and in order to gage the quantity of heat thus stored it was decided to measure approximately the total volume of the water in the area affected. To do this soundings were taken at selected sections of the basins, pool and stream.

As the temperature variations in certain portions of the area would be greater than in others, it was decided to divide the total area into zones over which the temperature variations were not large. Then:

$$\left.\begin{array}{l}\text{Total heat stored}\\\text{in the four zones}\end{array}\right\} = \Sigma \left\{\begin{array}{l}\text{Weight of water}\\\text{in each zone}\end{array}\right\} \times \left\{\begin{array}{l}\text{Net rise in}\\\text{temperature}\end{array}\right\}$$

The net rises in temperature between 10 a.m. and 4 p.m. have been obtained from an average of the rises recorded in Fig. 14.

The approximate dispersal factor was determined in the following manner:

Let ρ = dispersal factor of the day in B.t.u. per sq. ft. of water per hour per inch Hg difference in the vapor pressures corresponding to the water-surface temperature and the atmospheric wet-bulb temperature.

Average wet-bulb temperature reading = 49 deg. fahr.
Corresponding vapor pressure (V. P.) = 0.334 in. Hg.

$$\begin{array}{l}\text{Total heat quantity}\\ \quad X \text{ dispersed from}\\ \quad\text{the canal surface}\end{array} = \rho \times \Sigma \left\{\begin{array}{l}\text{(Area of each zone in sq. ft.)} \times\\ \text{(V. P. Hg corresponding to average}\\ \text{surface temperature—V. P. corre-}\\ \text{sponding to atmospheric wet bulb)}\\ \times \text{(Time in hours)}\end{array}\right.$$

$$\begin{aligned}461.8 \times 10^6 &= 31{,}200\,\rho \times (1.04 - 0.334) \times 6 \text{ (Basin A)}\\ &\quad + 23{,}900\,\rho \times (1.15 - 0.334) \times 6 \text{ (Pool)}\\ &\quad + 13{,}000\,\rho \times (0.93 - 0.334) \times 6 \text{ (Basin B)}\\ &\quad + 42{,}400\,\rho \times (0.82 - 0.334) \times 6 \text{ (Upstream zone)}\\ &= (132{,}000 + 117{,}000 + 46{,}500 + 123{,}500)\,\rho\\ &= 419{,}000\,\rho\end{aligned}$$

or

$$\text{Dispersal factor } \rho = \frac{461.8 \times 10^6}{419{,}000} = 1100 \text{ B.t.u. per sq. ft. per hr. per in.}$$

Hg difference in the vapor pressures corresponding to water-surface temperature and atmospheric wet-bulb temperature.

This factor represents the rate of cooling which actually took place during the test period and is therefore applicable only where the atmospheric and geologic conditions are similar. In conjunction, however, with heat-gradient charts its may be useful as a foundation on which to base an estimate of the degree of assistance which may be expected under particular conditions at other canal sites.

The investigation demonstrates strikingly that cooling is effected largely outside the circuit followed by the water between the circulating-water discharge and intake. The distance between these may be relatively small, but the heat will leave the circuit followed by the water and flow for a considerable distance along the canal,

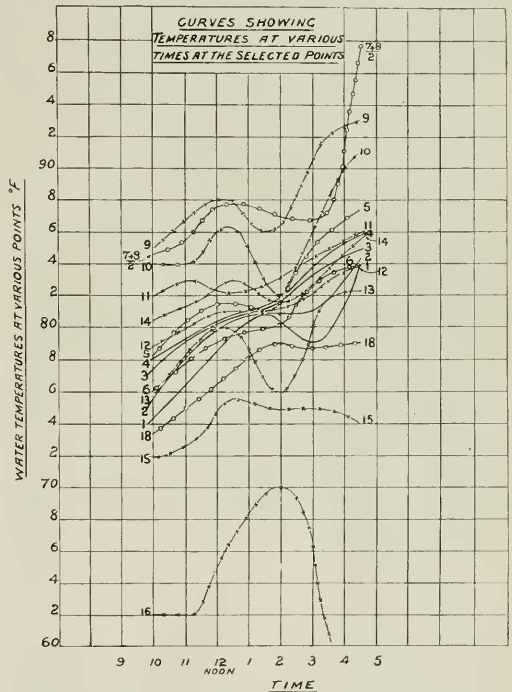

Fig. 14 Curves Showing Temperature at Various Times at Selected Points in the Canal Used as a Source of Condenser Water

thus increasing the cooling zone more or less adequately. In this case the heat actually flowed upstream for nearly a quarter of a mile against a slow current. (*The English Electric Journal*, vol. 1, no. 5, Jan. 1921, pp. 210–222, 8 figs., *ep*)

Proportioning Chimney Heights, Robt. Sibley and C. H. Delany, Members Am.Soc.M.E. The authors propose a method for ascertaining the diameter and height of chimneys in which a table and diagram given in the original article are used. It is claimed that by these means the fundamental dimensions of a chimney to produce a given amount of draft can be determined regardless of the kind of fuel used, provided the quantity of flue gas passing per hour can be approximately estimated.

In its turn the weight of flue gas passing per unit of time is said to depend for practical purposes on the weight of fuel burned and the percentage of excess air used in burning it.

This method is of interest as, in addition to giving the dimensions, it also apparently indicates the various combinations of heights and diameters of stacks to produce a given draft for the particular weight of flue gas considered.

The rule for altitude correction is given, and examples for calculating chimneys at sea level and at altitudes presented. (*Journal of Electricity and Western Industry*, vol. 46, no. 6, Mar. 15, 1921, pp. 299–300, 1 fig. and 1 table, *p*)

POWER PLANTS

Centrifugal Oil Cleaner. Description of a device developed at McCook Field, Dayton, Ohio. It consists of a spun copper bowl 5 in. in diameter and $1^1/_2$ in. high, mounted in a modified Liberty oil pump. It is driven by a steel shaft splined into the lower oil-pump gear of the Liberty-12 oil pump. The speed of this shaft is $1^1/_2$ times the crankshaft speed.

The oil is led from the oil tanks to the inside of the bowl which is rotating at 2550 r.p.m. when the engine is turning at 1700 r.p.m. The oil is set into centrifugal motion and all foreign matter of greater specific gravity than the oil is thrown and held to the inside edge of the bowl. A number of runs were made both with mineral lubricating oil and castor oil. In this latter test cold oil was mixed with fine emery powder, metallic filings and sand, which changed the color of the oil to a dark gray. After being run through the cleaner once the mixture emerged as clear as it was before it was mixed, and all of the emery, metallic particles and sand remained in the bowl.

The next test was made on a Liberty-12 engine run for 10 hr. at 1650 r.p.m. on a testing stand. The oil was not renewed during the run and after it was concluded the oil was emptied and the inside of the bowl carefully examined. It was found to be covered with a gummy deposit, in which a variety of substances were imbedded.

A study of the grit collected from the run reveals a large amount of iron and steel, which must have come from the piston rings and cylinder. There was also a large percentage of a very fine aluminum powder, which must have come from the pistons. A small quantity of bronze powder was observed, also babbitt bearing metal. Small chips resembling those from machining processes were present and also sand varying from very fine powder to small pebbles, and carbon in various forms and sizes. The sand may have come from the core sand that could not be cleaned out of the casting. There were also fine, brown particles that looked like sand but crushed easily and were presumably made up of dust taken in through the breather. The power required by the cleaner at 2250 r.p.m. varies from 1 hp. at 75 deg. fahr. to 0.35 hp. at 190 deg. fahr. (*Oil News*, vol. 9, no. 4, Feb. 20, 1921, pp. 21–22, 2 figs., *d*)

SPECIAL TOOLS

Boreas Cast-Iron Refuse Briquetting Machine. Description of a pneumatic press for briquetting cast-iron refuse.

It is claimed that by converting cast-iron filings and turnings into briquets not only can this material be usefully employed but the quality of the melt can be improved by making possible the introduction of silicon or manganese into castings in definite and concentrated form.

In the manufacture of the briquets cast-iron turnings and slaked lime are used, and the following mixture is quoted: 2 cwt. cast-iron turnings, 5 per cent slaked lime and 5 per cent water. The briquets made from this mass are placed on drying trays, allowed to remain there for some days, after which they are sufficiently hard to be piled for tempering. This latter, which generally takes from two to four weeks, depending on the water, can be done in the open air.

In dry weather it is advisable to water the briquets occasionally. Moisture in combination with the iron and lime gives a chemical reaction which forms a hard shell around the briquet. This is desirable as a final result, because it renders the briquet more suitable for handling, but must be avoided in the beginning as it might prevent the proper hardening of the inside.

If used in the cupola, they can be placed by means of a shovel, first of all filling in raw iron and old iron, thereafter the briquets, and lastly the cinders which act as a buffer to the following layer of raw iron and prevent the briquets from being crushed.

The "Boreas" press is adapted for pneumatic power and also for belt drive. In the first type the machine is a knee-joint press with the cylinder for compressed air suitable for pressure of 6 to 7 atmos. The belt-driven press is also of the knee-joint type but has a spindle instead of the air cylinder. The press makes three strokes per minute at a pulley speed of about 275 r.p.m., the power consumption being about $4^1/_2$ hp. The weight of the apparatus is approximately a ton and a half. (*Foundry Trade Journal*, vol. 23, no. 229, Jan. 6, 1921, p. 20, 1 fig., *d*)

STEAM ENGINEERING (See also Marine Engineering)

Rotary Steam Engines with Michell Thrust Bearings

Michell Crankless Steam Engine. Description of a high-speed engine designed by A. G. M. Michell, inventor of the Michell thrust block, for the purpose of testing whether by the use of these blocks it was practicable to construct crankless internal-combustion or steam engines which would presumably be lighter than engines of conventional type.

In the Michell engine the crank is replaced by a swash plate,

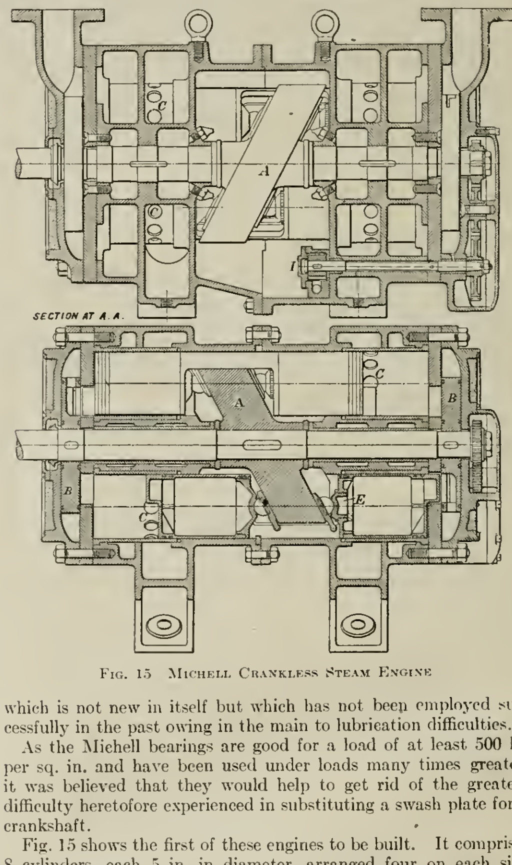

Fig. 15 Michell Crankless Steam Engine

which is not new in itself but which has not been employed successfully in the past owing in the main to lubrication difficulties.

As the Michell bearings are good for a load of at least 500 lb. per sq. in. and have been used under loads many times greater, it was believed that they would help to get rid of the greatest difficulty heretofore experienced in substituting a swash plate for a crankshaft.

Fig. 15 shows the first of these engines to be built. It comprises 8 cylinders, each 5 in. in diameter, arranged four on each side of the swash plate *A*, which is keyed to the driving shaft of the engine, which in its turn carries at each end a rotary valve *B* controlling the admission of steam to the cylinders. The engine works on the uniflow principle, the exhaust being discharged through ports *C*, of which there are eight for each cylinder, each $1^1/_8$ in. in diameter.

The pistons on opposite sides of the swash plate are rigidly connected in pairs to form a single unit, the weight of the unit being adjusted to that of the swash plate so as to secure perfect running balance. (Formula given in the original article.)

The thrust of the pistons is transferred to the swash plate through Michell blocks which are mounted on spherical seats,

and an ample supply of oil is maintained by means of a gear-driven pump.

Provision is made for adjusting the distance between the Michell blocks on opposite sides of the swash plate as at E. To permit this, one of the ball sockets is mounted on a screwed sleeve which can be adjusted by turning it by the notched head.

The engine was designed to run at 1200 r.p.m., but the tests have shown that this limit can be greatly exceeded. In the tests the steam was supplied at a gage pressure of 150 lb. per sq. in. and exhausted to a condenser in which a vacuum of 26 in. was maintained.

The swash plate was held at an angle of $27^1/_2$ deg., but Mr. Michell intends to reduce this in future engines to $22^1/_2$ deg., since the tests showed that the larger angle was unnecessary. The horsepower developed was 0.92 i.hp. per cylinder per 100 r.p.m., and it is believed the engine can be run at speeds up to 1500 revolutions. (*Engineering*, vol. 111, no. 2880, Mar. 11, 1921, pp. 290–291, 5 figs., *dA*)

TEXTILE INDUSTRY (See also Power)

Attention is called to the issue of *The Electrician* (London), vol. 136, no. 2229, February 4, 1921, containing several articles of interest to the textile industries, one of which, on Individual Gear Drive for Heavy Looms, is abstracted on a previous page under the heading Power. The other articles are: Some Considerations in the Application of Electricity to Textile Mills, by J. T. Randles, discussing estimates of power requirements, switch gear, electrification of new mills, balancing of group drives and the advantage of constant speed and steady turning which electric driving gives; Modern Methods of Driving Machines in Jute Manufacture, by T. Wodehouse and P. Kilgour, which discusses among other things the speed problem, methods of driving, carding processes, preparation of the warp and weft, cop winding and the various drives such as dressing-machine, loom and calender drives; and Continental Practice in the Electrical Driving of Textile Factories, by W. Dundas Fox, which is illustrated by numerous curves taken on various machines.

Flotation Method of Separating Coal from Slate and Rock

Froth Flotation Applied to the Separation of Coal. Various methods of separating coal from slate and rock have been tried, such as separation by heavy liquids, air separation, etc. At present the most usual system is washing the coal in jigs, but the Mineral Separations Company, which made a big success of the flotation process as applied to the separation of metallic ores, is now trying to employ the same principle for coal.

The new system comprises several separate operations. In the first place the coal has to be ground so that the particles will pass through a screen of $^1/_{10}$ linear inch aperture. It is then mixed with from four to six times its weight of water and the mixture agitated, either by means of a rotary agitator or by an injection of air, while a small quantity of a special reagent is added. The reagent may be an oil or a coal-tar product, and it is stated that some industrial waste products may be so used. Approximately a pound or so of the reagent is required for each ton of material treated.

The agitation in presence of the reagent produces a multitude of minute air bubbles which attach themselves to the coal particles and bring the latter to the surface, while the ash-forming slate sinks to the bottom. The process is of a continuous character, the material circulating through the plant until all the economically recoverable coal has been extracted.

It is claimed that the process is applicable to the removal of dirt and of non-combustible matter from crushed coal destined for coking purposes, the preparation of clean coal for the manufacture of briquets, and the recovery of coal from screenings or old pit heaps.

As regards the plant itself, it appears that the dimensions of one having a capacity of 600 to 1000 tons per 24 hr. are: length, 37.5 ft.; width, 16 ft.; and height, 15.5 ft.

A feature of the flotation system is the facility with which one grade of coal, by means of reagent control, is separated from another grade without screening or classification. Thus a coal comprising pure coal (i. e., no free ash, only fixed ash), bone coal and shale is separable into its component parts, so that the pure coal can be separated and the bone coal left with the shale; the bone coal can be separated from the shale and included with the pure coal, or else separated from the shale for boiler, locomotive, or producer use. Apart from the separation and recovery of the good coal contained in waste and low-grade coal, there are certain special advantages as regards the application of the system to the cleaning of coking coals. Ash reduction reduces cost of handling and permits of a larger efficient charge to the coke oven; richer gas and larger quantities of by-products are yielded, and a harder, denser and sufficiently porous metallurgical coke is obtained.

The following typical separation was effected in the cleaning of a coking coal carrying 10.14 per cent of ash in the raw state:

	Pure Coal	Bone Coal	Shale
Per cent by weight	87.20	2.4	9.5
Ash content, per cent	3.25	19.2	72.1

Obviously the bone coal can be mixed with the high-grade coal if required, but in this particular case it was proposed to make from the pure coal a high-grade coke carrying from 5 to 5.5 per cent of ash and to employ the bone coal for boiler or producer use, rejecting the shale as waste. (*The Iron and Coal Trades Review*, vol. 102, no. 2763, Feb. 11, 1921, p. 197, *g*)

Trial Flights and Acceptance Tests for New Types of Aeroplanes. A. G. H. Fokker. The ideal test pilot is, or should be, the designer of the machine. Unfortunately, this combination is very rare, and the designer has usually to rely on reports of others as to the properties of his machine. Until reliable recording instruments are in our possession, the "personal element" will predominate in the tests and "scientific" pilots are not always available.

The following are the main characteristics which an aeroplane should possess, and on which the test pilot should concentrate his attention:

Getting Off. The machine should possess sufficient directional stability while running along the ground. As soon as the flying speed is reached it should be able to get off without the use of the elevator.

In Flight. There should be no hunting, either in the horizontal or the vertical direction. The changing over from "power-flight altitude" to "gliding-flight altitude" should be automatic and quick. Even at the lowest flying speeds wing-flap controls should be possible. When executing curves there must be no tendency to go into a nose dive or spin. When side-slipping the machine should still be controllable. All rudder organs should be properly balanced.

Landing. Smooth landing depends very much on the type of landing wheels and their position. By proper construction, any tendency to leave the ground again can be checked. (*Het Vliegveld*, Jan. 1, 1921, abstracted through *The Technical Review*, vol. 8, no 11, Mar. 15, 1921, p. 256, *g*)

WASTE UTILIZATION (See Special Tools)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Sir Robert Hadfield Prize

Sir Robert Hadfield has offered through the Institution of Mechanical Engineers of Great Britain a prize for the best design of an apparatus to determine the hardness of materials accurately and suitable for application in metallurgical work for cases in which present methods partially fail. The award or awards will be made by the Council of the Institution. The present funds amount to £154 sterling. A portion of the fund may be awarded for communications which advance the knowledge of the methods of testing hardness. Communications should be accompanied by scale drawings or by models or examples of the apparatus. If the communication is likely to be of commercial value, provisional protection should be obtained before submitting it. Address the Secretary, Institution of Mechanical Engineers, Storey's Gate, St. James Park, Westminster, London, S. W. 1, marked "Method of Determining Hardness." Communications should reach him by December 1, 1921.

Research Associations in Great Britain

The number of British Research Associations under the license of the Board of Trade acting through the Department of Scientific and Industrial Research now totals twenty-three. Sixteen of these associations have already been listed in the issues of Mechanical Engineering for March, August and November, 1920 (pp. 181, 470 and 638). The seven additional associations are:

The British Leather Trades Research Association, 26 Thomas Street, London, S. E.; Secretary, Miss M. A. Stevens.

The British Launderers' Research Association, 62–5 Bank Chambers, 329, High Holborn, London, W. C. 2; Secretary, J. J. Stark.

The British Electrical and Allied Industries Research Association, 19 Torhill St., Westminster, London, S. W. 1; Director of Research, E. B. Wedmore.

The British Silk Research Association, The Silk Association of Great Britain and Ireland, Inc., Kingsway House, London, W. C.; Secretary, A. B. Ball.

The British Motor and Cycle Car Research Association, "The Towers," Warwick Road, Coventry; General Manager, H. R. Watling.

The British Cutlery Research Association, P. O. Box 49, Sheffield; Secretary J. M. Denton.

The British Music Industries Research Association, Northern Polytechnic Institute, Holloway, London, N. 7; Director of Research, Dr. R. S. Clay.

The British Jute Industry Research Association and the British Cast Iron Research Association have been approved by the Department of Scientific and Industrial Research, but as yet have not been licensed by the Board of Trade.

The British Aircraft Association and the British Association for Liquid Fuels for Oil Engines have proposed their memoranda and articles of association. Certain other associations are engaged in preliminary considerations.

The International Research Council at Brussels has started an inquiry regarding the possibility of an international auxiliary language for the purpose of reporting scientific matters.

Research Résumé of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which, in the opinion of the investigators, do not warrant a paper.

Apparatus and Instruments A3-21. Resistance Thermometers. The experience of the Bureau of Standards in the construction of resistance thermometers and a description of the resistance thermometers in use have recently been published as a scientific paper. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Apparatus and Instruments A4-21. Sampling Tubes for Steam. Tests to indicate the best position of sampling tubes have been made at West Virginia University by Carl H. Cather and H. S. Dilcher. To determine the true value of the quality of the steam for which different calorimeters had been used in connection with various forms of sampling tubes, the entire steam remaining in the pipe from which the samples were taken was allowed to discharge through a 1/4-in. orifice into a 5-in. drum 15 in. long. The temperature of this steam after the throttling action had taken place was determined by a resistance thermometer placed in the drum. The average pressure of the steam at the top and bottom of the drum was also determined. By assuming that the quality of the steam determined by this device, which was called a standard calorimeter, was correct, the errors of the various calorimeters could be found. The results show that in many cases an error of almost 2 per cent can be obtained. From certain sampling tubes errors of both positive and negative value were determined. The results indicate that the best form of sampling tube is one in which the holes are drilled in straight lines and the holes are 1/8 in. in diameter. The results are more uniform and have a smaller value when used in a descending current of steam. Small holes 1/16 in. in diameter are not as good as holes of larger size. Address Prof. John B. Grumbein, West Virginia University, Morgantown, W. Va.

Cellulose and Paper A1-21. Testing of Paper. Circular No. 107 of the Bureau of Standards is devoted to paper testing. It may be obtained from the Superintendent of Documents at 10 cents per copy. It describes the method of testing paper and the apparatus used for routine work. Instructions are given for making tests of various kinds for the quantitative determination of ash, sizing and rosin, as well as qualitative tests for the kinds of loading and the various sizing materials. A bibliography is also included giving useful books, periodicals and Government publications on the subject. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Cement and Other Building Materials A5-21. Concrete Mixer. A research performed at the Experiment Station of Purdue University on the best conditions for operating concrete mixers in regard to water control and speed. The report includes the strength and consistency of concrete, the time records for various operations, and the measurement of electrical power input. The report is published in the February 1921 issue of the American Concrete Institute. Address A. A. Potter, Director, Engineering Experiment Station, Purdue University, Lafayette, Ind.

Fuels, Gas, Tar and Coke A5-21. Fuel Research. Technical Paper No. 1 on the Assay of Coal for Carbonization Purposes: A New Laboratory Method, by Thomas Gray and James D. King, has been prepared by the Fuel Research Board. This describes the development of a method of coal assay from which the yield can be quickly and accurately determined. Experimental results of the paper explain how the method supplies this information. Price by post, 7d. Address Imperial House, Kingsway, London, W.C. 2.

Heat A7-21. Heat Transmission. The following papers by Dr. T. S. Taylor deal with work done by the Research Department of the Westinghouse Electric and Manufacturing Company in connection with the study of heat transfer:

A Hot-Wire Anemometer with Thermocouple, Am. Inst. Min. & Met. Engrs., Chicago Meeting, September, 1919.

Thermal Conductivities of Various Insulating and Other Materials. Am. Soc. M. E., New York Meeting, Dec. 2–5, 1919.

The Thermal Conductivity of Coil Wrappers. *Electrical World*, vol. 75, no. 7, Feb. 15, 1920, p. 369.

The Dissipation of Heat by Various Surfaces in Still and Moving Air. Am. Soc. M. E., St. Louis Meeting, May 24–27, 1920.

The Relative Conductor Temperature of Square and Round Insulated Cables, *Electrical World*, March 1920.

The Flow of Air through Small Brass Tubes. Am. Soc. M. E., St. Louis Meeting, May 24–27, 1920.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Air B1-21. Ventilation. Tests to determine the amount of air moved under various conditions. Carnegie Institute of Technology, Pittsburgh, Pa. Address David C. Saylor.

Air B2-21. Windmills. A new type of cam mechanism for use on windmills. University of Texas, Austin, Texas. Address Prof. Hal C. Weaver.

Apparatus and Instruments B2-21. DYNAMOMETERS. An investigation to develop a method of measuring power by electric means to eliminate the use and construction of expensive dynamometers. Brown University, Mechanical Engineering Department, Providence, R. I. Address Prof. W. H. Kenerson.

Apparatus and Instruments B3-21. FLUID METER. An investigation to develop an automatic liquid volumetric meter. Address Prof. Charles S. Brown, Vanderbilt University, Nashville, Tenn.

Electric Power B3-21. TRANSMISSION LINES. Trunk transmission lines is the subject of a bulletin in preparation by C. E. Magnusson, of the Engineering Experiment Station, University of Washington, Seattle, Wash.

Heat B1-21. HEAT TRANSFER. The Engineering Experiment Station at Pennsylvania State College has been working on the total transmission and conductivity of building materials. In their small "cubical" test box they have recently made special tests on the effect of flowing water on the transmission through concrete and brick. They have recently installed a new testing plate with blanks 2 ft. square over the measured surface. Special attention has been given to the measurement of temperature by thermocouples at various points on the plate and guard ring. Address Engineering Experiment Station, State College, Pa. R. L. Sackett, Dean.

Heat B2-21. HEAT TRANSMISSION. Bulletin 30 of the Engineering Experiment Station of Penna. State College on Heat Transmission through Cork Board and Air Space, by Arthur J. Wood and E. F. Brundhoefer, has been recently issued. The bulletin contains 38 pages of text and a large number of tables, curves and results, with a bibliography of 268 titles on heat transmission. The complete bulletin covers 139 pages. The tests show that conduction and transmission increase in a straight line with increase in temperature difference. The most reliable conductivity for Nonpareil cork board was 8.4 B.t.u. per sq. ft. per 24 hr. for 1 in. of thickness at 90 deg. fahr. difference in temperature. It was also found that the thickness of air spaces affected their insulating value. The experiments showed that the resistance due to multiple air spaces is not proportional to the number of air spaces. Address Prof. A. J. Wood, Pennsylvania State College, State College, Pa.

Heat B3-21. HEAT TRANSMISSION. Investigation relating to the heat transmission through a fiber insulating material known in the trade as "lith" and used in buildings as a heat insulator. University of Minnesota, Minneapolis, Minn. Address Prof. J. J. Flather.

Heat B4-21. HEAT TRANSFER. An investigation to determine the heat-transfer coefficient through various refractory materials. This necessitated the development of a method of measuring temperature for various phases of the steel industry. Carnegie Institute of Technology, Pittsburgh, Pa. Address David C. Saylor.

Heat B5-21. STEAM RADIATORS. Experiments covering 400 tests on different kinds of radiators and under different conditions have been made at Mason Laboratory, Sheffield Scientific School, Yale University. In connection with these tests the laboratory is coöperating with the Research Bureau of the American Society of Heating and Ventilating Engineers to find a standard method for testing radiators. Address Prof. E. H. Lockwood, Mason Laboratory, Sheffield Scientific School, Yale University, New Haven, Conn.

Heat B6-21. HEAT. Radiation and Convection from Radiators. An investigation to separate the heat transmitted from steam radiators by radiation and by convection is contemplated at the Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Heat B7-21. DISSIPATION OF HEAT. Dissipation of heat from wires and surfaces of various kinds, including the separation of the parts due to radiation and convection. The dissipation of heat from coils placed in parallel and in series and the effect of spacing. Research Department, Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa. Address C. E. Skinner, Manager.

Heat B8-21. HEAT TRANSMISSION. The Westinghouse Electric and Manufacturing Company is studying the subject of heat transmission through insulating materials and heat dissipation, which are important in the general study of the ventilation of electrical machines. Although much work has been done and reported (see *Heat A7-21*), much yet remains and the Research Department of the company is studying this question very minutely, giving special attention to the deteriorating effect on insulation. A number of papers have been published by Dr. T. S. Taylor, and a recent paper by Mr. Fetchheimer in the March *Journal A.I.E.E.* is based on the work carried out in the laboratory. Research Department, Westinghouse Electric and Manufacturing Company. Address C. E. Skinner, Manager.

Heat B9-21. PIPE COVERINGS. A bulletin giving the results of exhaustive tests on efficiencies of various kinds and combinations of commercial pipe covering is in preparation by the Engineering Experiment Station, State College of Washington. The tests are being made with equipment built especially for the purpose by which temperatures may be held constant 1/150 deg. by utilizing the expansive quality of hot oil with which the testing machine is filled. The oil-filled space constitutes the bulb of a large thermometer, the stem of which is a glass tube 1/8 in. in diameter.

Temperature measurement is made by a new White potentiometer built for thermocouple work. A study has been made of new methods of applying commercial pipe covering to secure greatest economic efficiency. This promises to be of considerable value.

Curve sheets are being prepared showing relations between temperature, thickness, yearly cost and savings for different kinds and combinations in commercial coverings. Address Dean H. V. Carpenter, Pullman, Wash.

Heat B10-21. HEAT TRANSFER TO OIL. A study is being made of the transfer of heat from steam to oil through steel pipes. The study is made to determine the heat transfer in warming pipes placed in oil tanks. Rensselaer Polytechnic Institute, Troy, N. Y. Address Arthur M. Greene, Jr.

Heat B11-21. HEAT TRANSFER THROUGH GLASS. A determination of the constant of heat transmission for glass is being investigated at the Rensselaer Polytechnic Institute, Troy, N. Y. Address Arthur M. Greene, Jr.

Heat B12-21. THE JOULE-THOMSON EFFECT IN SUPERHEATED STEAM. The Joule-Thomson effect in superheated steam is being investigated by a candidate for a doctor's degree at Harvard University. The method used is that developed by Trueblood at Harvard some years ago. It is hoped to cover a temperature range to about 600 deg. fahr. and a pressure range up to that corresponding to the saturation pressure of about 600 deg. fahr. Address Prof. Harvey N. Davis, Harvard University, Cambridge, Mass.

Heat B13-21. CRYOGENIC ENGINEERING. The research group in cryogenic engineering at the Harvard Engineering School are working on problems connected with the liquefaction of air for commercial application of fractionating this liquid to obtain pure nitrogen for fixation and pure oxygen for welding and cutting, with the commercial production of helium from natural gas, and the separation of hydrogen from water gas for commercial purposes. Theoretically the oxygen from 1000 cu. ft. of air should be separated by a power consumption of 3 hp-hr. It actually takes from 50 to 75 hp-hr. Work is being done to improve the output. An endeavor is being made to support a non-competitive research by the three larger companies building apparatus for producing liquefied gases. The Research Corporation of New York endowed by Dr. Cottrell has granted certain funds for the prosecution of research work in cryogenic engineering at Harvard. Those doing this work have devised, constructed and perfected apparatus for measuring latent heats at atmospheric pressure and are just finishing this investigation for pure oxygen at the end of the range. The same is true for apparatus for handling coexisting phases up to pressures of 300 to 400 lb. per sq. in., and this apparatus should by this time be in operation on nitrogen-methane mixtures used in the helium problem.

An air-flow meter which will give reliable results at pressures as high as 3000 lb. per sq. in. is now being used. Heat-transfer coefficients and friction heads for high temperatures, low temperatures and high velocities will be determined by this investigation. A tentative temperature-entropy and Mollier chart of air is being prepared. Address Prof. Harvey N. Davis, Harvard University, Cambridge, Mass.

Hydraulics B1-21. FLOW OF AIR. A study of the pulsating flow of air is being made for the Flow Meter Committee of the A.S.M.E. by Prof. Horace Judd and Mr. Bucher. Ohio State University, Columbus, Ohio. Address Prof. W. T. Magruder.

Hydraulics B2-21. DRAFT TUBES. A study of the distribution of velocity across draft tubes at different angles and the continuity of flow. Rensselaer Polytechnic Institute, Troy, N. Y. Address Professor Arthur M. Greene, Jr.

Internal-Combustion Motors B1-21. NEW CYCLE. The performance of an internal-combustion engine operating on new cycle. Yale University, New Haven, Conn. Address Prof. E. H. Lockwood.

Internal-Combustion Motors B2-21. SOLID-INJECTION OIL ENGINE. The development of a solid-injection fuel-oil engine to determine a correct valve gear and the methods of feeding fuel oil directly into cylinder. An investigation on materials suitable for high-pressure work. Carnegie Institute of Technology, Pittsburgh, Pa. Address David C. Saylor.

Lubrication B1-21. OIL GROOVES IN BEARINGS. A test to determine the effect of oil grooves in bearings under various conditions of load, size of shaft and other details. Carnegie Institute of Technology, Pittsburgh, Pa. Address David C. Saylor.

Machine Design B1-21. FILLETS. An investigation to discover the strength of fillets. Mechanical Engineering Department, Ohio State University, Columbus, Ohio. Address Prof. W. T. Magruder.

Metallurgy and Metallography B6-21. PHOSPHORUS AND SULPHUR IN STEEL. The Joint Committee on investigation of phosphorus and sulphur in steel has recently made a third statement regarding its work. The Committee on Statistics has supplemented its bibliography on this subject, which is available on application to H. L. Whittemore, Bureau of Standards, Washington, D. C. This committee is anxious to obtain samples of material which have been used under commercial conditions and have given good service or failed in service with ordinary and high sulphur and phosphorus contents. The Committee on Manufacture is making two series of tests: one series covering six grades of material of varying phosphorus and sulphur content, and one series in which the sulphur is added in the later stages of manufacture. Dr. G. K. Burgess is Chairman of this Committee.

The Committee on Tests under the chairmanship of Dr. F. C. Langenberger is making excellent progress on testing rivet bars.

Independent tests are being made at the Watertown Arsenal and the U. S. Experiment Station at Annapolis, as well as at the Bureau of Standards. A committee on Service Tests is being appointed. Address C. L. Warwick, Sec.-Treas., A.S.T.M., 1315 Spruce St., Philadelphia, Pa.

D—RESEARCH EQUIPMENT

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession

of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

The Barrett Company D1-21. The Barrett Company has a research laboratory at their Shadyside plant at Edgewater, N. J. This plant is equipped for the physical study of coal tar and for making synthetic chemical investigations. A description of the laboratories and the new laboratory building was given in *Chemical and Metallurgical Engineering* for Jan. 26, 1921. The company is at work on various organic problems and at present the research laboratory has a possible total floor space of 5400 sq. ft. accomodating more than 210 chemists, in addition to those at some of their other plants. Each laboratory in which inflammable organic material is used is provided with two exits and shower bath heads are placed in each laboratory room. Extinguishers are found in each room as well as sand pails and fire hose. The laboratory is also provided to care for large-scale work.

The laboratory is under the charge of a chief chemist and assistant chief chemist and the work is divided into ten divisions, among which are the tar and oil division, organic, research, experimental, plant, engineering and clerical. The Barrett Company, Edgewater, N. J. Address C. R. Downs, Chief Chemist.

Cutler-Hammer Manufacturing Company D1-21. The Research Department of the Cutler-Hammer Mfg. Co. is equipped with the usual apparatus for studying the discharge of electricity through gases and machinery of various descriptions and for testing the functioning of controlling apparatus. A supply of direct and alternating current of various voltages and frequencies, a supply of air and gas under pressure and a complete equipment of vacuum pumps, gages and electrical measuring instruments are found in the laboratory. The laboratory is equipped with primary standards for testing all measuring apparatus, and also with a glass-blowing shop and a machine shop for the construction of apparatus. The laboratory investigates physical phenomena relating to the development of electrical controlling apparatus and electrical phenomena in connection with their manufactured products. Cutler-Hammer Manufacturing Company, Milwaukee, Wis. Address Arthur Simon, Engineering Department.

E—Research Personal Notes

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

New York University E1-21. The Department of Mechanical Engineering of New York University is to coöperate in the investigations of the American Society of Heating and Ventilating Engineers. Its laboratory will investigate the question of pipe sizes for steam-carrying capacity and is also planning to do research work on economizers. Address Collins P. Bliss, Professor of Mechanical Engineering, New York University, University Heights, N. Y.

State College of Washington E1-21. The Engineering Experiment Station Staff of the State College of Washington at Pullman, Wash., includes Dean H. V. Carpenter as director and fifteen members of the faculty of the College of Engineering, of which one is giving his full time to research.

University of Utah E1-21. The Legislature of Utah has appropriated $25,000 for use in metallurgical research in the School of Mines and Engineering, University of Utah. This appropriation covers the expense of research during the last two years. Address J. F. Merrill, Director.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file at the offices of the Society.

Chemistry, Analytical F1-21. Water Softening. A bibliography of 13 pages, Search 3305. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

Fuels, Gas, Tar and Coke F1-21. Petroleum. History and Properties of Petroleum Fuels. A bibliography of 8 pages. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

Heat F1-21. Heat Transmission. A bibliography of 268 titles on heat transmission, prepared by Arthur J. Wood and E. J. Brundhoefer of Pennsylvania State College. Address Prof. A. J. Wood, State College Pa.

Metallurgy and Metallography F1-21. Phosphorus and Sulphur in Steel. A bibliography on the action of phosphorus and sulphur in steel has been prepared by the Sub-Committee on Statistics of a Joint Committee investigating this subject. Address H. L. Whittemore, Bureau of Standards, Washington, D. C.

Steam Power F1-21. Superheated Steam on Fittings. Effect of Superheated Steam on Steam Pipe and Fittings. A bibliography of 2 pages. Search 3302. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

THE INTERPRETATION OF BOILER-WATER ANALYSES

(Continued from page 320)

5 Determine by titration—
- *a* Acidity or
- *b* Alkalinity to phenolphthalein
- *c* Alkalinity to methyl orange.

6 Calculate from (5)—
- *a* Acidity as minus CO_3
- *b* Alkalinity as plus CO_3
- *c* Causticity as (OH).

7 Analyze and calculate—
- *a* Suspended matter
- *b* Total dissolved solids
- *c* Loss by ignition (indicate qualitatively if there is any blackening of the residue during heating)
- *d* Inorganic dissolved solids
- *e* Calcium
- *f* Magnesium
- *g* Aluminum
- *h* Iron and manganese as iron
- *i* Silica
- *j* Sulphates
- *k* Chlorides
- *l* Nitrates (nitrometer)
- *m* Ammonium (free)
- *n* Bicarbonates (HCO_3)
- *o* Carbonates (CO_3)
- *p* Hydroxides (OH)
- *q* Calculated inorganic dissolved solids [sum of (7-*e*) to (7-*p*), inclusive].

8 When hypothetical combinations are required, calculate as follows and make out a careful balance sheet:
- *a* Iron, magnesium and aluminum as sulphates
- *b* Calcium as carbonate
- *c* Any remaining calcium as sulphate
- *d* Any remaining calcium as nitrate
- *e* Any remaining calcium as chloride
- *f* If any carbonate remains, calculate as much of the available magnesium to carbonate as possible
- *g* Any remaining magnesium to sulphate
- *h* Any remaining magnesium to nitrate
- *i* Any remaining magnesium to chloride
- *j* Any remaining anions to corresponding sodium compounds, the value for sodium being assumed
- *k* Express silica as such.

9 Apply to (7) and (8) the following criteria:

a If the silica exceeds 5 parts per million (p.p.m.) and the causticity 30 p.p.m., report as industrial pollution and discontinue. If silica exceeds 5 p.p.m. and the causticity is low, report as having passed through sanitary filtration for verification.

b If the calculated inorganic dissolved solids (7-*q*) are less than 60 p.p.m. or acidity is indicated under (5-*a*), determine acidity or alkalinity by an electrometric titration and report as (9-*b*).

c If the calculated inorganic dissolved solids (7-*q*) lies between the limits 60–300 and the sum of (8-*b*), (8-*c*), and (8-*k*) is less than 60 per cent of this total, or if (7-*k*) exceeds 25 p.p.m. or (7-*l*) exceeds 10 p.p.m., determine a real value of sodium-potassium and report as sodium under (9-*c*).

d If the calculated inorganic dissolved solids (7-*q*) exceed 300 p.p.m., discontinue.

e If the sum of the calculated inorganic dissolved solids (7-*q*) is less than 60 p.p.m., apply the sanitary analysis which follows.

10 Determine—
- *a* Oxygen consumed by permanganate on two samples within the temperature range 60–80 deg. fahr., one at the end of 15 minutes, one at the end of 3 hours.
- *b* Nitrites (qualitatively)
- *c* Nitrates [transfer (7-*l*)]
- *d* Free ammonia
- *e* Albuminoid ammonia
- *f* Kjeldahl nitrogen.

11 Interpret the limits as follows:
- *a* Oxygen consumed: High = 4 p.p.m.; low = 0.6 p.p.m.
- *b* Nitrites (qualitatively): High, distinct, faint, very faint trace, none
- *c* Free ammonia: High, 1 p.p.m.; low, 0.1 p.p.m.
- *d* Albuminoid ammonia: High, 0.2 p.p.m.; low, 0.02 p.p.m.
- *e* Nitrates: High, 10 p.p.m.
- *f* Chlorides: High, 25 p.p.m.

12 Apply the limits of (11):

	Free Ammonia	Albuminoid	Chlorine	Inference
a	High	Moderate	Low	Sewer gas
b	High	High	High	Sewage
c	High	Low	High	Human pollution
d	Moderate	Low	Very low	Vegetable matter

e High oxygen consumed, particularly in the presence of low acidity, is confirmatory of sewage.

f If the albuminoid nitrogen is approximately one-half the Kjeldahl nitrogen, it is confirmatory of high organic purity. If it is appreciably greater than one-half, it indicates pollution.

A.S.M.E. Locomotive Boiler Code Adopted by Council

An important step in engineering standardization was taken March 23 at the Boston meeting of the Council of The American Society of Mechanical Engineers, when it adopted in its final form that portion of the A.S.M.E. Boiler Code known as the Locomotive Boiler Code. This Code is a noteworthy contribution to the cause of the engineering profession by the eminent engineers who made up the committee. The work of preparation has been long, and the designers and users of locomotive boilers as well as the general public should be sincerely grateful for the Committee's whole-hearted devotion to this work with the consequent heavy sacrifice in time and money.

The necessity for such an addition to the Boiler Code arose from the fact that, while the boilers of locomotives operated on railways engaged in interstate service are covered by the construction and inspection rules of the Interstate Commerce Commission, there was found to be a vast mileage of industrial and short-line railroads in operation in the various states which, by virtue of their location, are not subject to the Interstate requirements. As a result of calls for a Code to cover the construction of boilers of this class, the Sub-Committee on Railway Locomotive Boilers was appointed in 1916. This Committee consisted of F. H. Clark, Chairman, F. J. Cole, A. L. Humphrey, S. F. Jeter, Wm. F. Kiesel, Jr., and H. H. Vaughan. The work of this Sub-Committee was interrupted somewhat by the war, but its preliminary report was submitted to the Boiler Code Committee in April 1919. A month later it was printed and distributed at the Spring Meeting in Detroit, and accepted at the business meeting of the Society. It was thereupon published in the August issue of Mechanical Engineering. The Sub-Committee has been coördinating the points of view of all who would be affected by such a code and the final result approved by the Main Committee and the Council is now ready for use. H. V. Wille and Kenneth Ruchton of the Baldwin Locomotive Works were brought into the Committee, and with F. J. Cole and James Partington, appointed in place of A. L. Humphrey resigned, represented the locomotive manufacturers. Constructive assistance was given by the mechanical division of the American Railway Association through its representatives A. W. Gibbs, mechanical engineer of the Pennsylvania Railroad, W. I. Cantley of the Lehigh Valley Railroad, and N. A. Ferrier of the New York Central Railroad. A. G. Pack, chief mechanical engineer of the Interstate Commerce Commission at Washington, has expressed great interest in the Code, and with his staff of engineers has been in frequent attendance at meetings of the Sub-Committee.

During the past two years Mr. Clark, the original chairman of the Committee, has been in China as technical adviser to the Ministry of Communications at Pekin, and Mr. Vaughan has carried on the work of the Committee as acting chairman.

The new Code deals with the chemical and physical properties of materials of locomotive practice and includes the necessary formulas and methods of construction in detailed specification form for manufacturing safe boilers. Attention is given to the desire of the locomotive builders to maintain the lowest possible weight consistent with strength. As compared with stationary boilers with a safety factor of five, the allowable factor for locomotive shells is four. Requirements in the use of safety valves and their method of test are rigid, as are the hydrostatic tests specified.

The new Code becomes Part I, Section III, of the A.S.M.E. Boiler Code.

Boilers constructed in compliance with the Code may be stamped with the official A.S.M.E. Boiler Code stamp, which is obtainable at the headquarters of the Society.

The stamp will be applied to the dome of the boiler and will be accompanied by name of state, manufacturer's state standard number, name of manufacturer, state's number, year put in service, working pressure when built.

Address all inquiries on this Code to C. W. Obert, Secretary of the Committee, 29 West 39th St., New York, N. Y.

Boiler Code Interpretations

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 324, 328, 329 (reopened), and 331 to 341 inclusive, as formulated at the meeting of February 3, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 324

Inquiry: In the formation of the header element of a water-tube boiler to operate at 500 lb. pressure, with a tubular header 2 in. O. D., is it necessary that the ligaments between tube openings, where $1^1/_8$-in. cross-tubes are inserted on $1^1/_2$-in. pitch, shall be designed under the requirements of Par. 192?

Reply: It is the opinion of the Committee that while the strength of the construction may be calculated by the ordinary formula for cylinders, there are elements in the particular design which may result in the ability to carry higher pressures than would be allowed by the ordinary formula. The Committee therefore recommends that a test be made as provided for in Par. 247 of the Code. It further recommends that in making the test the pressure that will cause the material to be stressed to the yield point, be determined.

Case No. 328

Inquiry: Is it necessary, in the manufacture of boiler and superheater headers of open-hearth steel pipe, that the tensile strength be calculated on the basis of 55,000 lb., or is steel of lower tensile strength allowable in material of this form as permitted under Par. 28*c* of the Boiler Plate Steel Specifications?

Reply: If the material in the header conforms to a steel specification other than the steel-plate specification and shows a lower tensile strength than 55,000 lb. per sq. in., it is the opinion of the Committee that it is permissible to calculate the header design on the basis of this lower value the same as is permitted for steel-plate material as indicated in Par. 28*c*. See also Case No. 218.

Case No. 329 (Reopened)

Inquiry: What tensile strength shall be used for the calculation of the maximum allowable working pressure of pressure parts formed of steel castings of Class B grade or of seamless steel tubing material?

Reply: It is the opinion of the Committee that the tensile strength used in the calculation of pressure parts formed of steel castings of Class B grade or of seamless steel tubing shall be the minimum tensile strength determined from tests made on the test specimens located and taken as given in Par. 88 of the Code. While the Code contains no specific statement as to the tensile strength of the material used in seamless tubing, it is the opinion of the Committee that 50,000 lb. could be used as a basis for calculating the safe working pressure.

Case No. 331

Inquiry: Is it permissible, under Par. 311*a* of the Boiler Code, to use in the blow-off connection a valve and a cock formed in a single body casting, instead of two separate valves or a valve and a cock as specified in that paragraph?

Reply: It is the opinion of the Committee that the use of two valves, or a valve and a cock, combined in one body, does not meet the requirements of Par. 311*a* of the Boiler Code.

Case No. 332

Inquiry: Is it permissible under the requirements of the Boiler Code to attach a nozzle outlet to a pipe header manifold by inserting the nozzle through a hole in the header and peening the edges over inside the header, as shown in Fig. 10, the nozzle being autogenously welded to the header on the outside for steam-tightness?

Reply: It is the opinion of the Committee that this construction will not meet the requirements of Par. 186, as peening over of the inserted edges of the nozzle will not afford greater strength to withstand the steam pressure on the cross-sectional area of the nozzle than flaring as specified in Case No. 235.

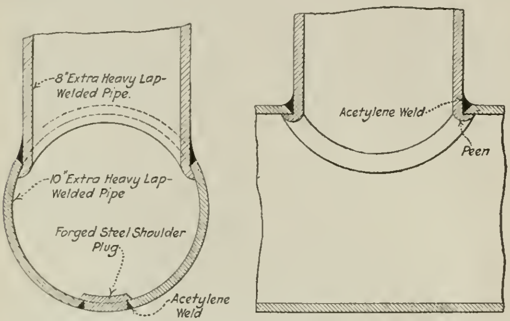

Fig. 10 Proposed Construction of Outlet Nozzle for Pipe Header with Inserted Edges of Nozzle Peened Over

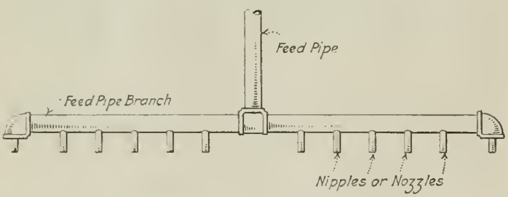

Fig. 13 Proposed Form of Internal Feed Pipe with Short Nipples for Outlets

Case No. 333

Inquiry: (*a*) Where a steam nozzle or safety-valve nozzle is placed upon a boiler drum in which the shell is made thicker than that required for giving a factor of safety of 5, do the requirements of Pars. 260 and 261 apply, which specify that the strength of the reinforcing ring shall be at least equal to the tensile strength of the maximum amount of the shell plate removed by the opening and the rivet holes for the reinforcement, and that the strength of the rivets in shear on each side of the reinforcement shall equal the tensile strength of the maximum amount of the shell plate removed by the opening?

(*b*) Does Par. 325 respecting allowable shearing and crushing stress on rivets used for attaching lugs or brackets apply to other than h.r.t. boilers for constructions where the weight is more evenly divided between the lugs than in the case of h.r.t. boilers?

Reply: (*a*) The requirements in Pars. 260 and 261 are based on the use of a shell having a thickness corresponding to a factor of safety of 5 at the seams, or weakest part of the shell. Where the thickness of the shell is greater than necessary to give a factor of safety of 5, the openings through the shell, to meet the requirements of Pars. 260 and 261, need not be reinforced to any greater amount than that required for such a shell.

Aside from the requirements in Pars. 260 and 261, the flange of the nozzle should be made substantial enough to withstand cross-strains to which it may be subjected through expansive strains of the piping, etc.

(*b*) Par. 325 applies to all types of boilers irrespective of the number of lugs employed.

Case No. 334

Inquiry: Is it permissible, under the requirements of Par. 332, to apply the A.S.M.E. Code boiler stamp to a boiler whose construction cannot be completed in the shop so as to subject the drum or any of its parts to hydrostatic test? Such a test would only be practical after the boiler has been erected in the field.

Reply: It is the opinion of the Committee that those boilers which cannot be completed and hydrostatically tested in the shop may have the stamping applied before shipment, final certification to be made after hydrostatic test is made in the field.

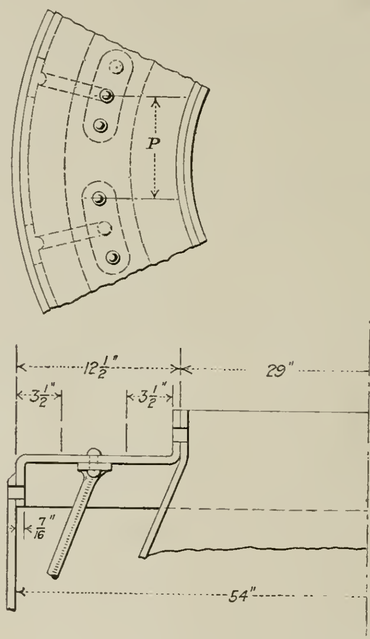

Fig. 14 Bracing of Top Head of Vertical Submerged-Tube Boiler

Case No. 335

(In the hands of the Committee)

Case No. 336

Inquiry: An interpretation is requested of the term: "or other opening," in Pars. 260 and 261 of the Boiler Code. Does it apply to openings cut for steel nozzles and boiler flanges?

Reply: It is the opinion of the Committee that the term, "or other opening," applies to openings cut for steel nozzles and boiler flanges, over 3-in. pipe sizes. (See last sentence of Par. 268)

Case No. 337

(In the hands of the Committee)

Case No. 338

Inquiry: Is it necessary in the construction of a 54-in. drum of a vertical water-tube boiler, which is formed of $1^3/_{16}$-in. plate with $3^1/_{32}$-in. tube holes, giving a ligament efficiency of 47.3 per cent, to use a butt strap $^7/_8$ in. thick as indicated in Table 1 of the Boiler Code? It is evident that the shell above the ligaments is much stronger than necessary for the desired working pressure

of 225 lb. per sq. in., and that $^{23}/_{32}$ in. thickness of shell is all that is necessary outside of the ligaments.

Reply: It is the opinion of the Committee that in the design of a joint for such a drum where the shell thickness is purposely made thicker than necessary for the working pressure in order to increase the ligament efficiency, the butt straps and riveting need not be proportioned for a greater strength than that necessary to carry the working pressure for which the drum is designed.

Case No. 339

Inquiry: Will an internal feed pipe formed of a main feed pipe with numerous small short nipples tapped into one side and with elbows at either end bushed down to similar small nipples, as shown in Fig. 13, meet the requirement of Par. 314 of the Boiler Code? This arrangement is made to force a certain amount of water to flow through the nipples instead of all through two nozzles.

Reply: It is the opinion of the Committee that the construction proposed does not meet the intent of this requirement, which specifies open ends of the pipe in order that incrustation may not under any circumstances cause stoppage.

Case No. 340

Inquiry: Is it permissible under the requirements of the Boiler Code to construct a 66-in. h.r.t. boiler for hot-water heating, to operate at pressures exceeding 50 lb., in which (*a*) handholes only are provided for cleaning and inspection, or (*b*) with manhole below the tubes only and tubes filling the entire upper space of the shell, there being no steam space required?

Reply: In the opinion of the Committee, this Case is fully covered by Par. 264, and the construction would be in accordance with the Code if sufficient provision was made for adequate inspection.

Case No. 341

Inquiry: What is necessary to determine the pitch of the braces to stay an annulus in the top head of a vertical submerged-tube boiler shown in Fig. 14 in which the annular space is $5^1/_2$ in. wide by 36 in. in inside diameter, and the boiler is to be operated at 100 lb. per sq. in.?

Reply: There is no specific rule in the Code applying to such construction. Par. 203*a* indicates the permissible coefficient *C* for the formula in Par. 199, from which the maximum distance between centers of rivets should be determined. Table 5 gives the permissible stress for braces which, in conjunction with the total pressure on the annulus (making proper allowance for angularity of the braces), designates the total brace area necessary. See also Case No. 308.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

The Largest Storage Reservoirs of the Western Hemisphere

To the Editor:

In the March issue of Mechanical Engineering, Robert Sibley, in a discussion of Recent Hydraulic Development on the Pacific Coast, stated that the storage reservoir of the Elephant Butte Dam in New Mexico is the largest in the western hemisphere, having a capacity of 2,600,000 acre-feet.

Perhaps Mr. Sibley by a slip of the pen wrote "western hemisphere" instead of "the United States of North America."

The Gatun Dam reservoir holds 4,201,000 acre-feet and the Gouin Dam reservoir at La Contre on the St. Maurice River, P. Q., Canada, 3,673,000 acre-feet. Thus their respective capacities are 62 and 41 per cent greater than that of Elephant Butte Dam reservoir. C. H. Ellacott.

Tampico, Mexico.

Calibration of Nozzles for the Measurement of Air Flowing into a Vacuum

To the Editor:

On further investigation of Mr. DeBaufre's paper, I have found that the apparent extreme accuracy of the discharge coefficient to which I called attention in my communication published in the April issue of Mechanical Engineering, was due to the fact that the experimental values were faired up before the table was compiled, and that the great variation from the average of the flow efficiencies given in column 6 of Table 2 actually represented the experimental results, even when the more usual coefficient of discharge was worked out.

I would therefore withdraw my previous remarks and at the same time call attention to the unsuitability of the shaped nozzle, such as was used in these experiments, for standard work. In this set of experiments, which were obviously carried out with great care, and for which the nozzles were obviously made as nearly geometrically similar as possible, the experimental discharge coefficient or flow efficiency varies by about $1^1/_2$ per cent. In my own work I always use geometrically similar square-edged orifices for standard measurements, as these are easy to reproduce with accuracy.

I find that such orifices can be reproduced so as to give coefficients of discharge that agree within $^1/_2$ per cent, and that calibration of a small orifice, say, one inch in diameter, can be applied with accuracy (i.e., to within plus or minus $^1/_2$ per cent) to orifices in the neighborhood of 30 in. in diameter.

My own tests on shaped nozzles fully bear out Mr. DeBaufre's results. It is impossible to predict the coefficient of discharge of such a nozzle within 2 or 3 per cent. John Hodgson.

Luton, England.

A New Hydraulic Turbine

To the Editor:

A new hydraulic turbine, the invention of Professor Banki of the Polytechnicum in Budapest, has recently attracted considerable attention in continental Europe. Simplicity, high efficiency, high rotating speed and low manufacturing costs are claimed for the new machine.

The principle of the Banki turbine is clearly shown in Fig. 1, where it is seen that the water passes through the blades of the runner *twice*, entering at the left and being discharged radially at the right, and imparting to the runner the greater part of its kinetic energy. The turbine runner is very simple in construction, consisting only of two end disks, a shaft and the blades, which latter are straight cylindrically curved plates with a center angle of about 72 deg.

It is claimed that the Banki turbine is equally efficient at low and high heads, and for low and high speeds, and that the speed and diameter can be selected to suit the requirements without sacrificing efficiency.

All types of Francis and Pelton turbines have a specific speed at which the efficiency is a maximum, and as the runner diameter and speed largely depend upon the quantity of water the turbine has to handle, the designer is restricted in their selection unless he is

willing to sacrifice the efficiency of the turbine. In the Banki turbine, however, the diameter of the runner is independent of the quantity of water passing through the turbine, so that the starting point of the designer can be the most advantageous speed, according to the nature of the drive, and the diameter may be determined to suit this speed.

Professor Banki states that the runner diameter may be obtained from formula: $D = 72.86\sqrt{H}/n$, where D is the diameter of the runner in feet, H the effective head in feet, and n the desired r.p.m.

The fact that the speed is independent of the quantity of water

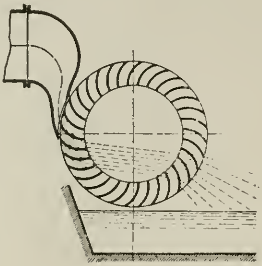

FIG. 1 THE BANKI HYDRAULIC TURBINE

is of very great advantage in hydroelectric power plants, where the cost of the electric generator decreases almost proportionally with the increase in speed.

The quantity of water determines the width b of the runner, which latter may be obtained from the formula: b = (0.024 to 0.03) nQ/H, where b is the width in feet and Q the quantity of water in cubic feet per second.

On account of its construction the setting of the Banki turbine may be very simple. It can be built in as easily as a water wheel and can replace existing water wheels without much change in the setting. It is claimed, moreover, that it is equally efficient at the low heads used until now in connection with water wheels, and at high heads of 500 ft. or more.

Several series of tests have been made in Budapest on Banki turbines of different diameters, under varying heads and different speeds, and efficiencies ranging between 80 and 90 per cent have been obtained, which compare favorably with those shown by other highly developed turbines. M. BURGER.

Elmhurst, L. I., N. Y.

Making Railroad Branch Lines Pay

TO THE EDITOR:

Commenting on the paper entitled Feeders for Railroads,[1] in which the author outlines the difficulties with which branch lines have to contend under present conditions and discusses the abandonment of unprofitable lines, practically the only solution of the problem that railroad officials have offered is to "raise the rates."

Presumably branch-line operation is unprofitable because of the limited volume of business—this bringing in insufficient returns for wages and maintenance.

Ordinarily the number of freight cars moved and the number of passengers carried may be computed in advance for each branch line. Unless new developments are forthcoming, the number of cars of freight in and out will be practically a constant from year to year; and the one train up one day and back the next that the author speaks of is sufficient to constitute good service. When milk is carried, or to take advantage of terminal facilities, or when more business develops, this becomes one mixed train a day each way. In a more thickly settled territory the demands for better passenger service are met by the addition of other trains, some of them mixed. These trains are a compromise between good service and bad, the public objecting to the slow, inadequate schedule and the railroad objecting to having to furnish service at so obvious a loss.

Mixed-train service is an abomination to passengers—its slow speed and the long waits, together with the infrequent trips, bring down their just wrath upon that intangible thing called "the company." Give these same people more frequent trains on a faster schedule and they will be willing to forego some comfort or pay more for the ride; also they will ride oftener.

To accomplish this, freight and passenger business should be separated as far as train service is concerned. By cutting freight service to not more than one train a day, the interests of all shippers would be served in a most satisfactory manner and at the minimum cost to the railroad As this would be strictly a freight train, its speed would be slow, making it possible to get along without the heavier rails and other trackwork necessary to heavy trains at high speed.

Now as to passenger service, why try to operate with steam trains? There seems to be no good reason why gasoline cars of three or four tons weight cannot be placed on all branch lines aside from the fact that officials do not want to do this. Railroad

GASOLINE CAR USED FOR PASSENGER SERVICE

men say that such cars are too light, will not stand up under continuous service, have to be repaired all the time, do not have carrying capacity. But these excuses seem ridiculous in view of the facts that locomotives have to be withdrawn at stated intervals for general overhauling (at, say, $4000 a shopping), have to be run monthly to shops for boiler work, are inspected and oiled and have minor repairs made at the end of each run.

A gasoline car can make as much speed as any branch passenger train. By the use of more than one car, or of trailers in conjunction with motor cars, a carrying capacity may be maintained to suit the traffic—and the operating expense is always in *direct proportion* to the load. The greatly reduced cost per passenger-mile makes it possible to provide more frequent trains for less money, and frequent service is the one thing that will induce more riding on branches.

Running out of Middletown, N. Y., there are two 15-mile roads—one an independent line and the other a branch of a trunk road. The branch line serves a more populous territory. Each road runs three trains a day each way, two of them mixed. The running time of the branch's mixed trains is an hour and a half, while a good bicycler can beat the passenger trains, pedaling over the automobile road that parallels the rails. The public has objected, as it always does, about slow, infrequent service and mixed trains—why shouldn't they when a gasoline car could shuttle the line continuously at 35 m.p.h. at less cost for the day's work than one steam-train trip? Traffic on this branch line remains about the same year in and year out, but with the public "served" using their autos as much as possible.

The short independent road is progressively managed—and therein may lie the reason for condemning branches generally, i.e., that the management has to do (get along) with the anti-

[1] Presented at the Annual Meeting, December, 1920, of the A.S.M.E. and abstracted in MECHANICAL ENGINEERING for January, 1921.

quated equipment given them and has to operate a road hundreds of miles away without the advantage of knowing actual needs, such as does one who is always on the ground. Upward of three years ago this independent road decided to try gasoline cars running out of Middletown.

Two cars like the one in the accompanying illustration were put on the road. The winter of 1920 severely taxed even the steam locomotives of all lines and this road maintained such service as it could, which was even more than the traffic warranted. There was no attempt to run the gasoline cars and they were sold to a southern road where they are running today. But as proof of the work of these cars, three more are being fitted up to start running this spring on the line out of Middletown.

The general manager has stated that it cost from 12 to 14 cents a mile to operate the cars, including gasoline and oil, repairs, two men at 40 cents an hour, and depreciation in four years. From this, one can reason that the cars could be junked at the end of four years and new ones bought without incurring any loss!

Moreover, the number of passengers carried while these cars were in service was double that of any previous similar period, which proves that people will ride more when they get service. While the number of steam trains was cut to two each way, there were added five gasoline trains and these latter (only) made stops at four wayside stations, maintaining the same schedule of 15 miles in 35 minutes.

This independent line is also paralleled by a good automobile road and the population, while less than along the branch line named, is distinctly of a better class financially and better able to ride in their own cars. There people knew that they were not being provided with Pullman service—they did not want it—but they knew that they were getting safe and speedy service and at intervals that served their convenience. They took pride in the "buses," as they persisted in calling them.

This was an interesting opportunity to compare two methods of doing the same thing. It is an engineer's comparison. Here are two roads as nearly alike as could be selected. One provides service as it has for forty years—the kind that is unsatisfactory to all concerned—and would abandon the line because receipts have not kept pace with increasing expenses. To abandon such a feeder would mean nothing to the trunk line, for it had a profitable through business.

But the independent road had no through business at all. Its little road constituted its entire stock in trade. To meet increasing costs, unconventional methods were adopted and a leaf borrowed out of the motor-truck book. Business was increased, net revenues increased, and the population turned into boosters. That is engineering. DONALD A. HAMPSON.

Middletown, N. Y.

Supplementary Reading for Students in Industrial Management

In the Correspondence Department of the January issue of MECHANICAL ENGINEERING, Prof. Bruce W. Benedict, director of shop laboratories of the University of Illinois, requested suggestions as to a list of books for supplementary reading by students in industrial management. In a second communication in the February issue, Professor Benedict appended a list used at the University of Illinois and urged again that the subject be discussed through this Department. Communications on this subject have been received from Robert B. Wolf and Walter N. Polokov, consulting engineers, of New York City, and from Hugo Diemer, director of LaSalle Extension University.

Mr. Wolf states that it is just as impossible to solve an industrial problem without a knowledge of the principles which have to do with the development of the individual centers of creation as it is to work in astronomy or mechanics without a knowledge of the laws of gravitation. For students who want to get at the problems of management evolution he suggests a study of evolution in the inorganic world, by taking up geology and by reading

- The Origin of the Species, by Darwin.
- Creative Evolution, by Bergson.
- The Art of Creation, by Carpenter.
- The Dore Lectures, by Troward.
- Science and Religion, by Keyser.

Mr. Polakov also believes that management deals primarily with men, therefore physiology and psychology should occupy the ranking place in a reading program. He states further that since management of industry aims at production of goods and wealth, a thorough grounding in economics is absolutely essential; and that, dealing with profound human problems, correctness of thinking and breadth of ideas are paramount, hence one must be well versed in mathematics and philosophy. With this end in view he submits the following list, divided into five groups:

Man:

- Mechanistic Conception of Life, by Loeb.
- Heredity and Environment in the Development of Man, by Conklin.
- Forced Movements, Tropisms and Animal Conduct, by Loeb.
- Psychology, by James.

Man and Society:

- Capital, by Marx.
- An Outline of the History of the Western European Mind, by Robinson.
- Vested Interests, by Veblen.
- America and the New Epoch, by Steinmetz.

Philosophy and Mathematics:

- Human Worth of Rigorous Thinking, by Kayser.
- Novum Organum, by Bacon.
- Human Engineering, by Korzybski (in preparation).

Managerial Principles and Practice:

- Organizing for Work, Industrial Leadership, and Work, Wages and Profits, by Gantt.
- Foremanship, standard course by Y. M. C. A.
- Industrial Manager To-day, by Webb.
- Principles of Scientific Management, by Taylor.
- Twelve Principles of Efficiency, by Emerson.
- Mastering Power Production, by Polakov (in preparation).

Miscellaneous:

- Scientific Management and Labor, by Hoxie.
- Industry and Humanity, by King.
- Fatigue Study, by Gilbreth.
- Fatigue and Efficiency, by Goldmark.
- Commercial Economy, etc., in Power Plants, by Smith.
- Time Studies and Rate Setting, by Merrick.
- Profits, Wages and Prices, by Friday.
- The Life and Work of H. L. Gantt, papers of 1920 Annual Meeting, A.S.M.E.

The list presented by Mr. Diemer was recommended by several members of the staff of La Salle and is as follows:

- Expense Burden, by Church.
- Business Statistics, by Copeland.
- Factory Organization and Administration, by Diemer.
- Twelve Principles of Efficiency, by Emerson.
- Office Management, by Galloway.
- Work, Wages and Profits; Industrial Leadership; and Organizing for Work, by Gantt.
- Motion Study, by Gilbreth.
- Principles of Industrial Engineering, by Going.
- Fatigue and Efficiency, by Goldmark.
- Human Factor in Works Management, by Hartness.
- Administration of Industrial Enterprises, by Jones.
- Hiring the Worker, by Kelly.
- Principles of Industrial Organization, by Kimball.
- Graphic Production Control, by Knoeppel.
- Getting the Most Out of Business, by Lewis.
- Time Studies as a Basis for Rate Study, by Merrick.
- Cost Accounting, by Nicholson and Rohrback.
- Applied Methods of Scientific Management, by Parkhurst.
- An Approach to Business Problems, by Shaw.
- Principles of Scientific Management, and Shop Management, by Taylor.
- Scientific Management, by Thompson.
- Purchasing, by Twyfort.

It is hoped that other discussion and other lists will be forthcoming, from which a "Three-Foot Shelf of Books" may be made up and kept on file at the headquarters of the Society.

Character and Knowledge in Engineering

Raymond Walters

QUALITIES of character as the prime factor in engineering success were stressed in the Carnegie Foundation report of 1915 in which were presented the opinions of 7000 engineers, all members of the four national engineering societies. In 94.5 per cent of the replies to a questionnaire sent these engineers the character group of qualities—character, judgment, efficiency, understanding of men—received a total percentage rating of 75, while knowledge of fundamentals and technique were rated at 25 per cent.

Good-scholarship in collegiate days as a mark of the eminent engineer is revealed in a recent study made under the auspices of the American Association of Collegiate Registrars, in which facts about the scholastic training of a group of distinguished engineers are given.

It is of interest to note at the outset that the criterion of eminence employed in this new study is the selection by the four national engineering societies of their officers and important committee members and representatives over a period of five years. This arbitrary criterion is of course not perfect. It leaves out success which is independent of professional activity and recognition, and tends somewhat to emphasize scientific and ethical aspects. However, reasonable limitation is a gain. Highly successful engineers outside of the societies are likely to be remiss in the obligation which Roosevelt once declared every man owes to the upbuilding of his profession. The scientific and ethical aspects are those which most profit the nation.

The most optimistic believer in the interrelation between good scholarship in college and good work in later life would hardly have ventured so high an estimate as the facts show the correspondence to be for the group of eminent engineers investigated. The facts are, that of the 392 collegiate graduates listed as eminent by the Registrars' Association and who represented the four national engineering societies,

182, or 46.4 per cent, stood in the highest fifth of their classes upon graduation;

109, or 27.8 per cent, stood in the second highest fifth of their classes upon graduation;

72, or 18.3 per cent, stood in the middle fifth;

14, or 3.6 per cent, stood in the next to lowest fifth;

15, or 3.8 per cent, stood in the lowest fifth;

The figures for the A.S.M.E. representatives in the "eminent" list are of particular interest to the readers of Mechanical Engineering. Of the 117 representatives of this Society, 54, or 46.1 per cent, were in the highest scholastic fifth; 30, or 25.6 per cent, were in the second highest fifth; 24 or 20.5 per cent, were in the middle fifth; 5, or 4.3 per cent, were in the second lowest fifth; and 4, or 3.4 per cent, were in the lowest fifth.

It was found that for five engineering schools which furnished more than half of the engineering graduates in the "eminent" list, the proportions were different as to the upper scholastic fifths. The second highest fifth led. The middle fifth more nearly approached the two higher fifths. The two low scholastic fifths had the same low percentage as in the total grouping.

The forty-seven other engineering schools which furnished 163 representatives and the twenty-three colleges having forty bachelor-of-arts representatives on the engineers' "eminent" list had exceptionally large percentages in the two highest scholastic fifths and small percentages in the low scholastic fifths.

Included in the Collegiate Registrars' study was an analysis of the scholastic training of all of the 730 eminent engineers embraced in the list. This disclosed that 580, or 79.5 per cent, were college graduates; 35, or 4.8 per cent, were college non-graduates; 115, or 15.8 per cent, had secondary-school training only. The student who starts and does not finish his collegiate course is shown in a particularly unpromising light.

Satisfactory returns could not be obtained covering the extra-scholastic activities of the eminent engineers in their college days—athletics, literary and engineering activities and social activities. No safe generalizations can be drawn. The one service the figures perform is, by contrast, to stress how definite and uniform for all groups considered is the correspondence between good scholastic work and good professional work.

Is there a contradiction between the Carnegie Foundation report of popular engineering opinion and the Registrars' Association findings as to scholastic standings? It does seem, from the Collegiate Registrars' facts, that popular opinion is overenthusiastic in its three-to-one proportion in favor of character qualities over knowledge of fundamentals and technique. This opinion might have been distinctly different had those who expressed it been aware of the very high scholarship records of the men they and their fellow-members have in the past elected to professional society leadership.

Aside from modification of overemphasis upon qualities of character, the Registrars' Association study does not contradict the Carnegie Foundation report. It combines with the latter in significant fashion. Taken together, the vote emphasizing personal qualities in engineering leaders and the study attesting the intellectual powers of engineering leaders (as shown by scholarship rank and later achievement) furnish an instance of the positive correlation between intellect and character which Prof. E. L. Thorndike, of Columbia, once expressed thus: "The brains and ability of the world have been, and still are, working for the profit of others."

For students in engineering colleges and for young engineers there are striking lessons in the results of these investigations.

Young men should beware of the notion that the student who does poor work or mediocre work has as good a chance for later eminence as the good student. Not *opinion*, but *facts*, explode this myth.

In the attainment of engineering success, as of all other success, time and chance, as a very old book tells us, cannot be entirely ignored. But luck is no persistent factor. The elements that tell in the long run are knowledge and character and the habit of action. The lesson for youth is a fresh emphasis upon these elements and upon the development of them in the one sure way—the efficient, whole-souled doing of each day's work.

Raymond Walters.[1]

[1] Registrar, Lehigh University, Bethlehem, Pa.; Secretary, American Association of Collegiate Registrars.

Lubrication and Hot Bearings

FROM time immemorial the bugbear of mechanics has been hot bearings. Most of us were brought up to fear heat in the bearings of machinery, and most of us have spent a good part of our lives in struggling to obtain a bearing and conditions that would allow that bearing to work without any heat at all.

Inspired by a paper on Practical Lubrication,[1] by Lieut. G. S. Bryan, U. S. N., I conducted some experiments with a pair of journals running in half-boxes with the upper side of the journal all exposed. A recess on the leading side of the journal was made in the box to receive oil and the corner was rounded to induce oil to run between the journal and the box. This recess was filled with a heavy oil. When the journal was revolved very slowly, nearly all the oil in the recess rolled under the journal and remained upon its surface. As the speed of the journal was increased oil was left in the recess, until at a speed of a thousand feet per minute of the journal nearly all of that oil was scraped off from the journal into the recess. Even at this speed there was sufficient oil left on the journal so that it did not abrade the metal. The temperature was so high that it would burn the flesh when the fingers were touched to the surrounding metal. Still that journal continued to run for a long time until the experiment was considered to be complete.

This heavy oil was then thoroughly cleaned from the journal and the boxes and kerosene oil put in its place. The spindle was revolved slowly and the kerosene oil left the recess and deposited itself on the journal. As the journal was gradually speeded up to a thousand feet per minute, the kerosene oil still appeared to remain on the journal; none was deposited in the recess and the journal revolved practically cold through quite a long period. While the heat from the first experiment with thick oil came very quickly, the kerosene-oil experiment was run for a considerable time, without excessive heating.

When an ordinary machine oil was placed in the recess and the journal revolved slowly, that oil all ran under the journal and seemed to remain on its surface. As this speed was gradually increased up to a thousand feet per minute, a portion of this machine oil was scraped off the journal and remained in the recess. Some heating was developed, but not enough to burn the flesh. This experiment was allowed to run through the same period of time as the others, but the heat did not increase above the original point, which was just where it was uncomfortable to the fingers held on the iron around it.

This oil was then removed and a so-called universal spindle oil was put in the same place. All of this oil left the recess at whatever speed the journal revolved and seemed to remain on the journal running continually between the journal and the box. So little heat was developed that it was just barely warm, regardless of the length of time it ran.

These experiments seem to show that Lieutenant Bryan is right when he says:

> The first effect of a high temperature in a bearing, then, is to thin the oil and thus decrease the friction. The effect of cooling the bearing is to increase the friction. There is no virtue in keeping a bearing at a very low temperature by the use of a considerable amount of cooling water, and there is no reason why a bearing should not be allowed to run at a high temperature as long as it is in good condition and is getting plenty of good, clean oil.

He further tells of one case of an average temperature of 205 deg. fahr. that was maintained for thirty days; and also of bearings which run regularly at temperatures of 190 deg. and 210 deg. that never cause any trouble.

Another thing that these experiments seemed to prove was that oil grooves in bearings are of no value. In most cases they are injurious, in that they reduce the bearing surfaces by just that amount. They also seemed to prove that instead of using graphite and various kinds of heavy oils when heat troubles arise, the best thing to do is to use a thin oil. This applies, of course, to high-speed bearings where the bearing is of sufficient area to sustain the load on the oil.

A further point brought out by these experiments—also brought out by Lieutenant Bryan—is that with oil constantly running on a bearing the oil can be exceedingly thin, because what is forced out by the load is constantly replaced by new oil and the bearing surfaces never come together.

But my thought in connection with this is that we have been deceived into a state of fear because there is heat in a journal. Any journal that will revolve long enough without abrasion to allow us to manifest this fear and worry, I consider to be perfectly safe.

Thousands of dollars are wasted every week in this country by the fact that mechanics stand and discuss and worry, and that engineers, superintendents and managers write letters, send telegrams and hold up the production in their works because the bearings of a machine are hot; and it is all useless fear.

C. H. NORTON.

Lester G. French

As the May issue of MECHANICAL ENGINEERING is being released for printing, word has been received of the death of Lester Gray French, on April 18, at the French Hospital in the city of New York. For the past thirteen years Mr. French has been editor and assistant secretary of The American Society of Mechanical Engineers, which organization he has faithfully and ably served throughout that period, developing the publications of the Society to a very high standard.

Mr. French was born in Keene, N. H., in April 1869. He received his technical education at the Massachusetts Institute of Technology, from which he was graduated in 1891 with the degree of S.B. Since 1897 Mr. French has been associated with technical publications; in that year he became editor-in-chief of *Machinery*, continuing in this position until 1906, when he resigned to take up the publication of technical books, among them being one of the earliest American treatises on the steam turbine, of which he was the author.

A more detailed account of Mr. French's professional career will appear in the June issue of MECHANICAL ENGINEERING.

Americans to Greet British Engineers

There is a very deep sense of gratitude on the part of the engineering societies of the United States for the part played by the engineers of Great Britain in the war.

The inability of Sir Robert Hadfield to come to the United States to receive the John Fritz medal developed the idea in the minds of the trustees of the John Fritz Medal Board of Award that the occasion of presenting this medal in England might be made the opportunity for expressing greetings by the engineers of the United States to the engineers of Great Britain.

The idea has been worked out and a deputation will be sent to the summer meeting of the Institute of Civil Engineers. This deputation will consist of a delegate from each of the four societies represented on the John Fritz Medal Board of Award. Dr. Hollis will accompany the deputation and carry the message from the American engineers. The delegates that have been selected are Charles T. Main, representing the American Society of Civil Engineers, Col. Arthur S. Dwight, representing the American Institute of Mining and Metallurgical Engineers, Ambrose Swasey, representing the John Fritz Medal Board of Award and The American Society of Mechanical Engineers, and Dr. F. B. Jewett, representing the American Institute of Electrical Engineers.

Digging Panama Canals Underground by Hand

IN his various addresses upon the subject of industrial waste, Herbert Hoover has repeatedly referred to the bituminous-coal industry as one of our worst-functioning industries. "These mines," he said at the Syracuse meeting of the American Engineering Council, "operate seasonally and erratically. They proceed from gluts to famines, from profiteering to bankruptcy."

This seasonal operation means for the miner less than 200 days'

employment each year; and what is of even greater import, he does not know from week to week when he will have work to do, nor how much work there will be.

For this condition the mining industry is not wholly to blame. Coöperation by the railroads and large consumers of coal are necessary if a more regular output is to be secured; and to accomplish this some governmental or other central agency is urgently needed as a directing force.

Coupled with this bad economic functioning is the friction and strife between the coal operators and the miners, and more particularly the miners' union, The United Mine Workers of America, as told in the almost daily dispatches from the coal fields of West Virginia. Apparently, the situation is a deadlock, with intolerable conditions existing, for the relief of which no constructive policy has yet been proposed by the mine owners.

In this connection, and as a comment on the present status of the coal-mining industry, our attention has been directed to a paper presented before the American Economic Association by Arthur J. Mason, of Chicago, in which he contends that the present unsatisfactory conditions could be greatly alleviated by abolishing the arduous (and probably useless) labor of shoveling the coal by hand into the mine cars after the face has been shot in the mine. He would introduce machines for loading the coal, which, while primarily a mechanical problem with apparently little bearing on the general economic situation, he believes would have a most important psychological effect on the whole industry.

Mr. Mason is an ore engineer and approaches coal mining as an outsider, influenced more by the accomplishments in his own field than by the habits and precedents of the coal-mining industry. He has lived through the period of the remarkable development of the mechanisms for the handling of ore with which engineers are familiar and sees the possibility of an equally useful development in coal mining.

He gives the rather startling figures that 1,000,000 men in the United States pass their working lives down in the mine or near the pit mouth, and as part of their work shovel each year nearly 700,000,000 tons of coal into railroad cars from its resting place in the mine. "It is," he states, "as though we were to go back to spading our land in agriculture instead of plowing it."

How much coal is 700,000,000 tons? According to Dr. Mason's calculations, the coal mined in the months of January and February alone would fill the whole Panama Canal; and according to figures given out at the time the Canal was completed, the actual excavation for the Canal was about one-third the volume of coal now mined in this country each year!

The relation which mechanical loading might be expected to have to the general mining operation may be thus briefly summarized:

For each 1,000 tons brought up from the mine, 100 acres is provided below as a labyrinth of entries, rooms, tracks, switches, ventilation devices, so that in a big mine, raising 5,000 tons, almost a section a mile square is so organized—a bewildering city underground. This area largely arises from the pseudo-ownership which every miner acquires of his room or rooms, technically known as his "place."

In a coal mine, like any tunnel, the work will proceed with the frequency with which a face is shot. In Southern Illinois faces are shot about once in four days. If faces were shot every day, it would follow that the area to be kept alive, with all the agencies mentioned, would be correspondingly reduced. Two and one-half acres would become the equal of 10 acres, and the cost of mining over what is paid the so-called miner (about twice the miner's wages) would be reduced accordingly.

Machine loading would necessarily abolish the institution of "places" in coal mining. A group of six men with a loading machine and motor should average 100 tons of coal per hour loaded in mine cars, the crew passing from room to room.

In spite of the large economic waste in the coal industry in various directions, Mr. Mason believes that the greatest waste is in manhood. Hours needlessly spent in a mine is not what men most desire. "Can one conceive," he says, "a proposal more splendid than to bring to the surface and the light of day thousands of men to do some finer and better work, and to bring upward with them their families and dependents?"

Submarine Against Submarine

In his entertaining book, The Victory at Sea, Rear-Admiral Sims gives what to many will be a new conception of the efficacy of the submarine in hunting and destroying the submarine during the war. The belief is general that the most successful hunter of the submarine was the destroyer, and so far as absolute figures are concerned this is true. Destroyers, with their depth charges and gun fire, sank more U-boats than any other agency; but relatively the submarine itself proved a more destructive enemy of the submarine than did the destroyer.

The Allied destroyers, about 500 in number, sank 34 German submarines; auxiliary patrol craft, such as trawlers, yachts, etc., about 3000 in number, sank 31; while the Allied submarines, only 100 in number, sank 20. It is therefore evident that the latter surpassed in their effectiveness the most formidable of the surface anti-submarine vessels.

Admiral Sims regards this work of the Allied submarines as in a way the most astonishing development of the naval operations of the war. "It is particularly interesting," he says, "because from that day in history when the submarine made its first appearance the one quality which seemed to distinguish it from all other kinds of warship was that it could not be used to fight itself." It was supposed to be a vessel valuable almost exclusively to the weaker sea powers. It could destroy battleships and cruisers, but not vessels of its own kind, and for that reason has not been popular with nations having strong navies. Early in 1800 Robert Fulton endeavored unsuccessfully to sell to England the inventions incorporated in his submarine *Nautilus*. St. Vincent, then First Lord of the Admiralty, refused, saying, "Why encourage a kind of warfare useless to those who are masters of the sea and which, if successful, will deprive them of this supremacy?"

In connection with the recent war, Admiral Sims says it is important that we keep in mind the fact that the submarine is only occasionally a submarine; and that for the greater part of its career it is a surface boat. In the long journeys which the German U-boats made to the hunting grounds which lay in the Atlantic trade routes, they traveled practically all the time on the surface of the water. The ability to submerge was merely a quality which was utilized only in those crises when the submarine either had to escape a vessel which was stronger than itself, or planned to attack one which was weaker.

The simple fact that the submarine can accomplish its destructive work only when submerged, and that it can avoid its enemy only by diving, makes it plain that it must always hold itself in readiness to submerge at a moment's notice and remain under water the longest possible time. Its storage batteries, therefore, must not be wasted by needless under-water travel—in other words, it must spend all its time on the surface where it can be propelled by its Diesel engine, except during those brief periods when it is attempting to attack a ship or escape an enemy.

The situation with the Allied submarines, however, was quite different. The Allied submarine commander did not have to maintain such constant readiness to submerge and to remain submerged, for there were not German surface vessels operating on the high seas and he had no enemies to fear. The British and American fleets were attending to that. For this reason he was not compelled to economize his electric power so strictly and he could, in fact, spend a considerable part of his time under water. This gave him a great advantage in hunting U-boats, for he could cruise around all day at slow speed, with only the periscope of his submarine showing. "Just as the German U-boat could 'spot' an Allied destroyer at a great distance without being itself seen," says Admiral Sims, "so could the periscope of the Allied boat spot the German submarine on the surface long before this tiny object came within the view of the U-boat conning tower. Our submarine commander could remain submerged, sweep the ocean with his periscope until he picked up the German enemy; then, still under water, and almost invariably unseen, he could steal up to a position within range and discharge a torpedo into its fragile side The German submarine received that same treatment which it was itself administering to harmless merchantmen; it was torpedoed without warning; but, as it was itself a belligerent vessel. the proceeding violated no principle of international law."

Industrial Relations and the Engineer

Basic Principles Presented at Joint Meeting of New York Section of A.I.E.E. and Metropolitan Section of A.S.M.E.

"WHEN the mariner has been tossed for many days in thick weather and on an unknown sea, he naturally avails himself of the first pause in the storm, the earliest glance of the sun, to take his latitude and ascertain how far the elements have driven him from his true course. Let us imitate this prudence and before we float further, refer to the point from which we departed that we may at least be able to conjecture where we are now."

This quotation from Daniel Webster's speech against Hayne—made by Dr. Ira N. Hollis with particular reference to the present status of industrial relations—expressed the purpose of the joint meeting of the New York Section of the American Institute of Electrical Engineers and the Metropolitan Section of the American Society of Mechanical Engineers on March 25. The program included dispassionate statements of the conditions on which correct industrial relations must depend and emphasized the necessity for analytical considerations of these conditions by engineers.

In his opening remarks, the chairman of the meeting, Walter Rautenstrauch, vice-president of the J. G. White Management Corporation and professor of mechanical engineering at Columbia University, emphasized the importance of the fundamental principles upon which permanent industrial relations should be based. He outlined these as: (1) The need for relationship between employer and employee, which is well founded economically; (2) the establishment of principles relative to the obligations of the parties involved as well as their rights; (3) a foundation of justice; (4) the organization of both parties for work, emphasizing production and service rather than organization for the acquisition of something.

The first speaker of the evening was Dr. F. H. Giddings, professor of sociology at Columbia University, who presented the social background of the problem of industrial relations. Professor Giddings made a distinction between the social background and the economic foreground. Economic questions enter into all disputes between organized labor and organized capital. A sound judgment of industrial relations rests equally, however, on an understanding of the social phases which relate to life itself, for the support and amelioration of which wealth is the means. He stressed as important the fact that the fundamental trouble with capitalism is that it is not capitalistic enough, in that wealth is not being used productively but is being wasted or even immorally squandered. The sensitive spot is not found in the distribution of wealth, therefore, but in the reactions of present-day industrial relations upon the wage earner himself. Men develop full lives not only through creative work but through relations with fellowmen as members of society. Through membership in numerous organizations and as citizens, opportunity for usefulness, happiness and self-expression are found. Therefore, quite normally, wage-earning groups desire a larger opportunity to share in the organization and control of things industrial. This desire is recognized in the present talk on industrial democracy. In closing, Professor Giddings emphasized the importance of a careful consideration of all the factors and the bringing forth of a solution by unprejudiced people. He outlined the place the engineer should have in bringing forth this solution on the basis of an intellectual rather than an emotional approach to the problems to be solved.

The address by Doctor Hollis, which will be printed more fully in a future issue of MECHANICAL ENGINEERING, developed the rise of the industrial worker coincident with the development of mechanical power. In it he analyzed the true measure of the rise of the industrial worker, in increase in numbers, increase in power of organized workers, gain in wealth, increase in opportunity and the development of a satisfaction through work for others, and dwelt on this last item almost entirely. He measured the rise of any human effort or agency by its tendency to minister to the satisfactions of life. No gain in numbers, power or wealth that does not accomplish this is a permanent gain.

Dr. S. M. Lindsay, professor of social legislation at Columbia University, related the recent enactments of state legislatures affecting industrial relations. He outlined the steps taken to protect women and child workers, compulsory safety enactments, and the laws passed to establish arbitration in industrial conflict.

Bringing up to date a paper delivered before the Spring Meeting of The American Society of Mechanical Engineers in 1919, L. P. Alford, editor of *Management Engineering*, presented the recent developments in organizing personal relationships in industry. Mr. Alford's previous paper reviewed the major lines of development of the 35 years preceding 1919.

Under the heading of Profit-Sharing Plans, Mr. Alford differentiated true profit sharing from allied schemes such as stock subscriptions, wage bonuses, saving methods, etc., and presented the conclusions of the National Industrial Conference Board Report of an analysis of 41 experiences of profit sharing, as follows: (1) From experience with profit sharing in the past with plans now in operation, profit sharing has been successful for limited periods; (2) judging by the long list of abandoned plans, and the comparatively small number that have endured more than a few years, the effectiveness of profit sharing in surviving the many vicissitudes of an industrial enterprise is decidedly uncertain; (3) in the light of the high percentage of abandonments due to dissatisfaction among the workers, it is reasonable to conclude that wise and efficient management plays a very important part in the success of profit-sharing plans.

Considering Methods of Wage Payment, two tendencies during the past two years were noted: (1) To pay an addition to earnings based upon an established wage-payment system; and (2) to return to piece-rate payments during the past few months.

Under Methods and Laws to Reduce Hazards in Industry, Mr. Alford reviewed the enactments in the various states. Progress was indicated by the reduction in accidental deaths from 35,000 in 1912 to 22,000 in 1919. In contrast the deaths on American highways have increased from 35,000 in 1912 to 100,000 in 1920.

Employment management made rapid strides in 1919 and 1920. At the present time with unemployment in industry estimated at 4,000,000 workers, employment departments are being disbanded or curtailed in proportion to reductions of working forces. Present conditions are leading to a study of the economic justification of employment work that will bring about a more substantial basis for the employment and personnel functions in the future.

Mr. Alford listed the declared rights of labor recognized by the proclamation creating the National War Labor Board which were written into the Versailles Peace Treaty. There have been no new developments in this regard in the past two years because of lack of Senate action concerning the Peace Treaty.

In his consideration of the Mutual and Joint Control Methods, he referred to the report of President Wilson's Second Industrial Conference in December 1919, and to the developments leading to the establishment of the Kansas Industrial Court.

In closing, Mr. Alford emphasized the engineering character of recent attempts in organizing human relationships in industry and pointed out the important responsibilities of the engineer in organizing and treating human activities on the same basis of knowledge as prevailing in the more technical aspects of the engineer's work.

The final paper of the evening was presented by Mr. A. L. De Leeuw, consulting engineer, who gave a critical analysis of the human tendencies that must be recognized in industrial relations. Working from the premise that the engineer must know the properties of the materials with which he builds, Mr. DeLeeuw outlined the situations brought about in industry by the two outstanding human tendencies, or sets of qualities, with which we have to reckon—the individualistic and the social. The necessity for leadership was expressed and the importance of well-informed, well-balanced labor leaders was emphasized. In closing, Mr. De Leeuw stated the need for some form of definite understanding between employee and employer by which the product and compensation are properly fixed and their relative relation maintained.

A.S.M.E. to Meet in Chicago May 23-26

Preceded by Trip to McCook Field and Followed by Excursion to Rock Island, Chicago Program Has Diversity, Interest and Value

THE 1921 Spring Meeting of The American Society of Mechanical Engineers bids fair to be the most popular of any of the recent Spring Meetings. The excursions to McCook Field and Rock Island Arsenal offer interesting opportunities which, coupled with the main sessions at Chicago, will attract the mechanical engineers of the entire country.

Excursion to McCook Field

The membership is afforded a fine opportunity to become acquainted with the nerve center of aeronautic development in this country. On Saturday, May 21, the Aeronautic Division, jointly with the S.A.E., is to visit McCook Field, Dayton. The morning is to be spent in an inspection of the shops and experimental laboratories, looking over the latest designs in aeroplanes and motors, parachutes, radio apparatus, cameras, etc. After lunch, to be served at the cafeteria, there will be a flying program. The evening will be spent at the Engineers' Club, when the gathering will be addressed by some of the leaders in aeronautic development.

Rock Island Excursion

Following the meeting at Chicago, two days—May 27-28—will be spent at Rock Island Arsenal with the Army Ordnance Association. The Ordnance Division will present an interesting program, and an inspection of the plant will be made. The visit to the Arsenal is limited to citizens of the United States who are not engaged in the manufacture of munitions for foreign governments. Saturday the 28th will be given over to a golf tournament to be held on the Rock Island links.

The Chicago Meeting

The four days, May 23-26, to be spent in Chicago are planned to include a remarkable collection of valuable professional sessions, attractive entertainment and interesting plant visits. The Professional Divisions have coöperated with the Committee on Meetings and Program to provide the strongest program possible. In so far as is practical, the plants to be visited have been selected with the idea of supplementing the technical program.

Chicago itself, the fourth largest city in the world, with its stock yards, its immense terminals, its remarkable schemes for municipal development, its wonderful educational institutions, and its fine parks, is well worth a visit, even without the attraction of the Spring Meeting. This virile metropolis—the center of a large number of A.S.M.E. members who are earnestly planning for the comfort of their guests—will undoubtedly attract the largest number thus far assembled at a spring gathering of mechanical engineers.

The tentative program given on the following page presents a great diversity of interest and is worthy of careful study.

Chicago Session

In accord with past practice, a session will be devoted to the consideration of the vital problems pertaining to the section of the country adjacent to the Spring Meeting city. The Chicago transportation problem has been selected as a subject of commanding interest, not only locally but nationally. In this session the Western Society of Engineers is coöperating, and its Terminal Committee has arranged a program touching on the problems of Chicago as a Mid-Interior Rail-Water Gateway. This program is valuable to all engineers in that it gives insight into the magnitude and complications of one of the earth's greatest railroad centers. Various phases of this subject will be presented by J. R. Bibbins, consulting engineer, Dept. of Transportation and Communication, Chamber of Commerce, Washington, D. C.; E. J. Noonan, engineer of the Chicago Terminal Commission; Hugh E. Young, engineer of the Chicago Planning Commission; and Bion J. Arnold, consulting engineer, of Chicago.

Industrial Education and Training

Realizing the growing need for development in education and training in the industries, an evening session has been assigned for a powerful presentation of this subject. The Committee on Training for Industries plans to have able speakers give their experience in developing successful schemes of training in the various industries, and with the important points brought out hopes to develop considerable activity in the future educational work of the Society. The fact that a recent Congressional Committee reported that the United States had fallen from first place to seventh in its educational standing among the nations, has emphasized the vital need of a careful consideration of this subject by the engineering profession.

Business Session

The important topic for discussion at the business session will be the extended changes planned in the Constitution and By-Laws.

Power Test Codes Hearing

Three codes will be presented for discussion and adoption during the Spring Meeting. These Codes are those dealing respectively with Reciprocating Steam Engines, Evaporating Apparatus, and General Instructions.

Sessions of Professional Divisions

Forest Products

At the Spring Meeting the Forest Products Division plans to complete its organization and will present three papers on phases of the development of engineering in the utilization of forest products.

Fuel

The general topic of the Fuel Session is the utilization of Mid-Western Fuel, and, as indicated on the program, the presentation will be made by men who have had broad experience in this field. An excursion to the successful pulverized-coal-burning plant of the Milwaukee Electric Railway and Light Company is planned in connection with this session.

Machine Shop

The Machine Shop Division is to discuss the development in machine tools and machine-shop practice brought about by the automobile industry, which has increased the sizes of machine-tool units, developed new requirements in accuracy, and revolutionized methods of manufacture.

Management

An interesting paper on the Organization of an Engineering Society, by Morris L. Cooke, will be presented at the Business Session. Its discussion, however, will be carried on during the Management Session, inasmuch as this paper was procured through the Management Division. It is also planned to receive the preliminary report of the Committee on Terminology which has been appointed jointly by the Taylor Society, the Society of Industrial Engineers, National Association of Cost Accountants, Industrial Relations Association of America, and the American Institute of Accountants. This committee has been working for several months on the preparation of a dictionary of terms used in management engineering, and the adoption and use of these terms will do much to clarify management literature and assist in the development of the art of management. L. W. Wallace will present an account of the work of the American Engineering Council Committee on the Elimination of Waste.

Materials Handling

The application of material-handling machinery to road building has been adopted by this Division for its Spring Meeting topic. The country needs better and cheaper highways, and the province of the mechanical engineer in providing machinery to satisfy these needs is well defined. This session should therefore be of great

interest not only to the designers of road-building machinery, but to the users as well. Motion pictures of modern road-building machinery will be shown.

Power

The Power Division is to coöperate with the Chicago Section of the A.I.E.E. and the mechanical and electrical sections of the Western Society of Engineers to provide the program for this session. The general subject will be Power Resources of the Middle West, and two strong papers will be presented.

Railroads

The Design of Large Freight Locomotives is the general subject selected for the Railroad Session. The three papers provided on this subject will furnish the basis for an interesting discussion of the needs and problems of the motive-power departments of the railroads.

General Papers

Five valuable papers will be presented at the two General Sessions. Mr. White's paper on the hydraucone regainer gives the history of the development of this device which has proved valuable in increasing the effectiveness of hydroelectric installations. Mr. Johnston's paper presents the results of a number of tests of oxy-acetylene welding and cutting blowpipes. These tests were made by the Bureau of Standards for the War Department shortly

(Continued on page 356)

TENTATIVE SPRING MEETING PROGRAM

Chicago May 23-26, Headquarters at Congress Hotel

(Other subjects or changes to be announced later)

Monday Afternoon, May 23

Business Meeting: Discussion of Changes in Constitution and By-Laws
On the Organization of an Engineering Society, M. L. Cooke

Monday Evening, May 23

Reception and Dance at Congress Hotel

Tuesday Morning, May 24 (Simultaneous Sessions)

FUEL SESSION

Recording Ash-Pit Loss from Chain-Grate Stokers, E. G. Bailey
Boiler Tests with Pulverized Coal, Henry Kreisinger and John Blizard
Limitations of Mechanical Stokers Utilizing Mid-West Coals, E. H. Tenney
Capacity and Efficiency Limitations of Stokers Using Mid-West Coals, John E. Wilson
Discussion of Smoke Problem with Reference to the Health of the Community, Dr. John D. Robertson
Latest Requirements of the City of Chicago in Furnace Design, with Special Reference to Hand-Fired Boilers and Limits of Each Design, Frank Chambers

MACHINE-SHOP SESSION

Influence of the Automobile on Gear Cutting and Gear-Cutting Machinery, H. J. Eberhardt
Influence on Power Presses, Dies and Special Tools as a Result of the Demands of the Automobile Industry, Henry J. Hinde
Lathe Design, R. E. Flanders
Interchangeable Manufacture, C. B. Lord

MANAGEMENT SESSION

Industrial Waste, L. W. Wallace
Report of Committee on Management Terminology
On the Organization of an Engineering Society, (Discussion) M. L. Cooke

GENERAL SESSION

Capacity Tests of Dry-Vacuum Pumps, by the Low-Pressure Nozzle, S. B. Redfield
Report on Efficiency Tests of a 30,000-kw. Steam Turbine, H. B. Reynolds

Tuesday Afternoon, May 24

Excursions

Tuesday Evening, May 24

Session on Training for the Industries

Wednesday Morning, May 25 (Simultaneous Sessions)

CHICAGO SESSION

Some Aspects of the Problem of Chicago as the Mid-Interior Rail-Water Gateway, J. R. Bibbins
Development of Air Rights in Connection with City Freight Houses, E. J. Noonan
Freight Movement by Motor Trucks, Wiewpoint of Carrier and Public, Hugh E. Young
Freight-Tunnel System as a Terminal Distribution Agency, J. R. Bibbins and E. J. Noonan
The Function of the Terminal Survey, J. R. Bibbins
The Relation of Steam Roads to Rapid-Transit Development, Bion J. Arnold

GENERAL SESSION

Investigation of Oxy-Acetylene Welding and Cutting Blowpipes, R. S. Johnston
Interpretation of Boiler-Water Analyses, J. R. McDermet
The Hydraucone Regainer, Its Development and Applications in Hydroelectric Plants, W. M. White

PUBLIC HEARING ON POWER TEST CODES

This Session will be devoted to the discussion of the proposed Power Test Codes on General Instructions, Reciprocating Steam Engines, and Evaporating Apparatus.

Wednesday Afternoon, May 25

Excursions

Wednesday Evening, May 25

Dance at Congress Hotel

Thursday Morning, May 26 (Simultaneous Sessions)

RAILROAD SESSION

Design of Large Locomotives, M. H. Haig
The Needs for the 2-10-2 and Other Heavy Freight Locomotives for Road Service, A. F. Stuebing
Necessity for Improvement in Design and Operation of Present-Day Locomotives, H. W. Snyder

MATERIALS HANDLING SESSION

Planning and Organizing a Road Job for the Mechanical Handling of Material, C. D. Curtis
Road-Construction Plants, B. H. Piepmeier
The Mechanical Side of Highway Construction, R. C. Marshall, Jr.

FOREST PRODUCTS SESSION

Woodworking Education, Dean Moon

POWER SESSION

Power Resources of the Middle West.
(Authors to be announced later)

Thursday Afternoon, May 26

Excursions and Moving Pictures

Secretary Hoover Resigns from Presidency of F.A.E.S.

Executive Board of American Engineering Council Meets at Philadelphia—New Member Societies—L. W. Wallace Representative on U. S. Board of Surveys and Maps

An important meeting of the Executive Board of the American Engineering Council of the F.A.E.S. was held at the Engineers' Club of Philadelphia on April 16. The closing action of the session was the acceptance of Herbert Hoover's resignation as president of the Council. As a member of the Executive Branch of the Government Mr. Hoover felt that he could not consistently direct the activities of an organization which is engaged in furthering national activities involving legislation. In a resolution of regret at Mr. Hoover's retirement the Board voted its appreciation of his leadership during the organization period of the Council and his initiation of policies and effort.

In regard to the question of Government reorganization, it was voted to renew the activities of the National Public Works Department Association for the establishment of a National Department of Public Works. Committees of the Association in every state will coöperate with the Smoot-Reavis Committee of Congress in a movement to reorganize the Department of the Interior by placing the public-works functions of the Government under central control. The Council will also support the Smoot-Reavis Committee in its program for the revision of the governmental machinery to promote economy and efficiency in departmental administration.

A progress report of the Committee on the Elimination of Waste in Industry said that a series of intensive assays of more than 100 industrial plants has been completed, and that the field workers have made their reports. These reports are being collated and will be made public sometime in June.

Following the meeting of the Executive Board, a dinner, attended by 600 engineers, was given at the Bellevue-Stratford Hotel by the Engineers' Club of Philadelphia and its fourteen affiliated societies, comprising a membership of more than 4600 in Philadelphia and Eastern Pennsylvania. The presiding officer was Guilliaem Aertsen of the Midvale Steel & Ordnance Company and president of the Engineers' Club of Philadelphia. The toastmaster was Major Joseph A. Steinmetz, past-president of the Engineers' Club and chairman of the Aeronautic Division of the A.S.M.E. Mr. Aertsen, as president of the Club, presented Herbert Hoover, president of the F.A.E.S., with a certificate of honorary membership in the Engineers' Club of Philadelphia. Following the presentation Mr. Hoover delivered an address on the Reorganization of Government Departments.

Other speakers were Dean Dexter S. Kimball of Cornell University, vice-president of the F.A.E.S., whose subject was The Federated American Engineering Societies; J. C. Trautwine, Jr., editor of Trautwine's Hand Book, whose topic was The Engineers of Philadelphia, and George W. Pepper, lawyer and publicist. A summary of Mr. Hoover's address follows:

One problem of the new administration that has received the attention and thought of the organized engineers of America for many years is that of the reorganization of the Federal Government. To any student of Federal organization, one sweeping and fundamental necessity stands out above all others,—that the administrative units of the Government must be regrouped so as to give each of the great departments more nearly a single purpose. Such functions as public domain, public works, assistance to veterans, public-health functions, aids to navigation, to industry, to trade, purchasing of major supplies, are each and every one scattered over from four to eight departments, most of which are devoted to some other major purpose.

Economies can be accomplished from a public point of view by an elimination of the overlap in these different units of administration through unification into groups of similar purpose. The real economy to the nation, however, does not lie here, however great this may be, but it lies in their more effective functioning in their daily relation to the public.

As a result of the war the responsibilities for the major purposes of the Treasury, War and Navy Departments have been enormously increased. In the interests of efficiency they should not be called to responsibility for the administration of matters not pertinent to their major functions.

There is also some confusion between executive, advisory, and semi-judicial functions. One of the tendencies of government, both local and national, during the last twenty years, has been to add executive functions to commissions and boards created primarily for advisory or regulatory purposes. Executive functions cannot rise to high efficiency in the hands of Government boards in which each member has a separate responsibility to the public and is primarily engaged in a semi-judicial function.

Furthermore, during the last few years there has been a great growth of independent agencies in the Government reporting directly to the President, until his office is overburdened almost beyond the point of endurance, and coördination with executive departments is rendered extremely difficult. It is neither possible nor advisable to place all these outside organizations within the departments, but much could be done to mitigate the situation.

The economic changes in the world, growing out of the war, and their reflex upon our trade and industry make it vital, if we are to maintain our standards of living against increasing ferocity of competition, that we shall concentrate and enlarge our national effort in the aid, protection, stimulation and perfection of our industrial and commercial life.

We want no paternalism in government. We do need in government aids to business in a collective sense. In a department we do not want to either engage in business or to regulate business. We need a department that can give prompt and accurate diagnosis from both a foreign and domestic point of view of economic events, of economic tendencies and of economic ills; that can promptly and accurately survey economic opportunity, economic discrimination and opposition; that can give scientific advice and assistance and stability to industry in furnishing it with prompt and accurate data upon production, supplies and consumption; that can coöperate with it in finding standards and simplifications; that can by broad study promote national conservation in industry and the elimination of waste; that can study and ventilate the commercial side of our power possibilities; that can study and advise national policies in development of rail, water, and overseas transportation; that in fact covers, so far as government functions can cover, the broad commercial problems of trade, industry, and transportation. This can be accomplished more by coördination of existing governmental facilities than by increased expenditures.

Three More Societies Join F.A.E.S.

The membership of The Federated American Engineering Societies has been increased in recent weeks by The Boston Society of Civil Engineers, the Milwaukee Engineering Society and the Duluth Engineers' Club. There are a number of other societies which will probably become affiliated with the F.A.E.S. before July 1, at which time the opportunity of coming in as a Charter Member will expire. At present the membership of the Federation includes 24 engineering societies and clubs, including a total membership of nearly 50,000 engineers.

Council Appoints Representative on U. S. Board of Surveys and Maps

The American Engineering Council's Committee on Procedure has appointed L. W. Wallace, executive secretary of the Council, as its representative on the United States Board of Surveys and Maps. Mr. Wallace succeeds Alfred D. Flinn, secretary of Engineering Foundation, and has been assigned to the Committee on Coöperation.

The Federal Power Commission, Army Air Service, and Naval Aviation have been added to the membership of the Board and committees have been reorganized so as to better distribute the work. The Advisory Council of the Board has asked the American Engineering Council to assist in obtaining an adequate program involving a larger appropriation for topographic maps.

F.A.E.S. Establishes Permanent Headquarters in Washington

Permanent headquarters of the F.A.E.S. have been established at 719 Fifteenth Street, N. W., Washington, D. C., with L. W. Wallace, secretary of the Federation, in charge. In addition to office accommodations for the staff of the Federation, sufficient space has been obtained to provide a conference room for those who may desire to use headquarters for a meeting place. It will be the purpose of headquarters at all times to render as much personal service as possible for engineers who visit Washington, enabling them to transact business matters with the minimum amount of effort on their part. The new office will continue the services rendered by M. O. Leighton and A. C. Oliphant in the Washington office of Engineering Council.

History of Machine Industries of Windsor, Vt., Now in Preparation

There are certain localities, particularly in New England, where mechanics of early days did pioneer work of strikingly original character and which have had a marked influence upon the development of the machine industry of the entire country. One of these is Windsor, Vermont, and it is gratifying to learn that a complete history of the rather surprising mechanical accomplishments of that place is being prepared by Mr. Guy Hubbard of the Engineering Department of The National Acme Company of Windsor. Since in the ninety-two years of their existence companies which are either descended from or related to the Windsor concerns, men who learned their trades there, and things manufactured there, have become widely scattered, valuable information relating to this history has often been found available from very unsuspected sources. Further information would be greatly appreciated by Mr. Hubbard and full credit given for whatever is used.

Among the more important things which have been either originated or developed to a practical state in Windsor are the rotary gear pump, the Lincoln-type milling machine, the turret lathe, breech-loading and repeating small arms, and automatic screw machines. Among the famous mechanics who have a place in the history of these developments are James Hartness, Governor of Vermont, and the late Charles E. Billings, who are both Past-Presidents of The American Society of Mechanical Engineers.

Poster Issued in 1865 Showing Diversified Product of One of the Old Machine Firms of New England (Reproduced from a Distorted Photograph)

The line of machine industries at Windsor, which has continued unbroken down to the present time, was founded in 1829 as The National Hydraulic Company, builders of Hubbard's patent rotary pumps, which are still manufactured, practically unchanged, by The Fales & Jenks Machine Company of Pawtucket, R. I., who purchased the patent rights at Windsor in 1833. In 1830 The National Hydraulic Company built and installed the 20-hp. pump of the first water works of St. Louis, Mo. They later went into the manufacture of Kendall's patent underlock rifles, becoming in 1844 Robbins, Kendall & Lawrence, and in 1849 The Robbins & Lawrence Company (1849–1858). This was one of the most famous gun and machine-tool concerns of its time and did much to spread the interchangeable system both in this country and abroad. In 1854 and 1855 they built most of the machinery for the Royal Armory at Enfield, England.

The Robbins & Lawrence Company, through successive changes, under Mr. E. G. Lamson became The Windsor Manufacturing Company (1865–1869), which was succeeded by The Jones and Lamson Company. In 1888, following Mr. Hartness' identification with this company, it was moved to Springfield, Vt., and became The Jones and Lamson Machine Company, the manufacturers of the Hartness flat turret lathe. The Windsor Machine Company then took over the old shops at Windsor, where the Gridley automatic screw machine was developed, a machine original in its conception like its noteworthy predecessors. In 1915 this company became a part of The National Acme Company, being known as its New England Plant.

One of the many interesting documents which Mr. Hubbard has unearthed in the course of his researches is a poster, reproduced on this page, which was issued in 1865 by the Windsor Manufacturing Company and constituted a catalog of their products. This poster is a striking illustration of the diversity of output which machinery manufacturers attempted before the days of specialization, and is of particular interest because of the remark-

able character of the machines illustrated. There is shown a reasonably complete line of machine tools and metal-working machines, including a Lincoln miller and an indexing milling machine. In those day every town with water power had its sawmill, a requirement met by this company. Stone-channeling machines and air-driven diamond-pointed rock drills were produced primarily to meet the needs of the marble quarries of Vermont. And, finally, a magazine rifle was manufactured which is said to have done very effective service in some of the closing battles of the Civil War, and which was certainly in marked contrast to the muzzle-loading arms used to a large extent throughout that war.

American Railway Engineering Association

Annual convention in Chicago, March 15, 16 and 17. The rail committee, in their report, expressed surprise at the attitude of the mills toward the rail specifications adopted by the association in 1920. The mills refuse to roll rails of any weight under a contract requiring full compliance with the 1920 specifications and will roll according to modified specifications only if large extras are paid. The committee will determine during the coming year whether it is best to adopt two specifications, one without running into extra price and the other requiring an extra price, or to accept only one specification without extra cost over the manufacturer's base price, the association to be given a list of specific refinements in the order of their importance so that roads requiring a higher grade of rail will have the benefit of the association's judgment on the most valuable of such refinements. M. H. Wickhorst discussed the relation of shattered steel in fissured rails to the mill end of the rail. C. W. Gennet, Jr., explained how unsafe rails can generally be traced to unsound ingots. A new cut track spike specification was adopted by the association on the recommendation of the committe on track. A new bolt specification was also adopted. Bolts, other than heat-treated, must be of mild-carbon steel with a tensile strength of not less than 50,000 lb. per sq. in. and an elongation of not less than 15 per cent in 8 in. Heat-treated or high-tensile bolts must be of carbon or alloy steel and conform to the following minimum requirements: Tensile strength, 100,000 lb. per sq. in.; yield point, 70,000 lb. per sq. in.; elongation in 2 in., 15 per cent; reduction of area, 40 per cent.

Brief History of Engineering Council

At the final meeting of the Engineering Council held at Washington in December 1920, a committee consisting of J. Parke Channing, Philip N. Moore and Alfred D. Flinn was appointed to prepare a brief history of the activities of the Council from the time of its establishment in the spring of 1917 to its termination in December 1920. The Committee states that the report, which is now completed, is not a full record of the Council's activities but is rather a summary of examples indicating the variety of subjects handled and the methods of dealing with them. Through the instrumentality of Engineering Council, notable progress has been made in organizing the engineers of the country for service not only to the members of the profession, but also to national, state and local governments and the public, in matters of general interest in which the technical training and experience of engineers should be utilized. The work so well inaugurated will be carried on by the American Engineering Council of The Federated American Engineering Societies.

An Opportunity for Young Engineers

The attention of young engineers residing in Greater New York is called to the formation of a Tank Corps within the National Guard of the State of New York. The Eighth Coast Command Armory located in the Bronx has been designated as the home of the new organization. Recruiting is done at the office of L. K. Davis, ex-major, Tank Corps, A.E.F., 347 Lexington Ave., New York City, every Monday night between eight and ten, and at the Armory on Thursday nights.

The tank corps is a branch of the service essentially an engineering problem. It requires a diversified knowledge embraced in the activities of the engineering societies, and it is hoped that junior members of the various engineering societies may be interested in this Tank Corps.

A.S.M.E. TO MEET IN CHICAGO MAY 23–26

(Continued from page 353)

after the armistice. Mr. Redfield's paper presents a simple and effective method for making capacity tests with dry-vacuum pumps. Mr. McDermet's paper on boiler-water analysis throws new light on this old subject. The tests on the 30,000-kw. steam turbine reported by Mr. Reynolds in his paper present valuable data of tests of large units which are not generally available.

Hotels

It is anticipated that the hotels in Chicago will be crowded during the week of the Spring Meeting. To assist the membership in securing hotel reservations, a double card was sent out with the Spring Meeting circular. One half of the card is to be sent to the hotel and the other half to the Chicago Hotel Committee, who will keep in touch with the hotels and make sure that the member's request for reservation is given prompt and careful attention by the hotel. The Chicago Hotel Committee has no responsibility to engage rooms for the members, however, its sole duty being to secure the necessary action by the hotel.

Special Railroad Rates

Arrangements have been made with all railroad lines, except those in the Southeastern and Canadian Passenger Associations, by which members may obtain a considerable reduction in their railroad fares. When buying a ticket to Chicago ask your agent for a special rate certificate. Upon presentation at Chicago a half-fare rate home may be obtained, provided the return is over the same route used to go to Chicago. This special rate applies only if 350 certificates are presented, but as it applies to all rates over 67 cents, every member is requested to ask for a certificate so that those coming from long distances may be assured of the reduction.

ON THE ORGANIZATION OF AN ENGINEERING SOCIETY

(Continued from page 325)

Engineering Societies or otherwise, regular assemblies of engineers of all varieties should be held where subjects common to all can be discussed and plans for the public welfare developed in which the entire body of engineers can have a part.

It is not good engineering to drift to a result. We do not do it in our professional work. We decide what we want to do and then we do it, and usually pretty well within the time set. The time element is usually as easily determined as the design. It is something of the same spirit that we must get into our group activities. We must seek to formulate the community's problems and then cope with them as we do with the narrower problems of our everyday practice. No scheme of engineering organization will be satisfactory which does not include the broadest possible coöperation with other organized groups—professional, industrial, commercial, and social. Coöperation is of the very essence of the future. Our thought should be centered on the avoidance of any limits in our plans for coöperation.

In conclusion, it may be said that if in our organized activities we make efficient service our watchword and have uncompromising publicity as a day-to-day policy, we will provide a type of leadership which the people will follow. The old disciplines are largely gone. It is up to the technologists—"the profession of creation and construction, of stimulation of human effort and accomplishment,"[1] to erect those standards of effectiveness and aspiration to which a race may rally.

[1] Principles of Mining, Herbert Hoover.

Standard Power Test Codes

ALL who have occasion to test power-plant apparatus will be interested in knowing that the large A.S.M.E. committee which has for some time been revising the Power Test Codes of 1915 will hold its first public hearing on May 25 at the Congress Hotel, Chicago. This public hearing will constitute one of the sessions of the Spring Meeting of The American Society of Mechanical Engineers.

The three Codes which will be presented for discussion and adoption at this hearing are those on Reciprocating Steam Engines, Evaporating Apparatus, and General Instructions. Those who are not able to go to Chicago are urged to send in written criticism and discussion. A pamphlet containing reprints of these Codes in their present form will be supplied on application to the A.S.M.E. Committee on Power Test Codes.

Removable Lighting Fixtures

Recognizing the growing demand for removable electric lighting fixtures for domestic use, the New York Section of the Illuminating Engineering Society devoted its January meeting to a full discussion of the subject. The papers presented and the discussion which followed their presentation bore more or less directly on the proposal that standard ceiling and bracket fixtures be so equipped with plug connections that any layman can put up or take down any fixture at will.

So much interest was aroused at this meeting that the Council of the Illuminating Engineering Society has since considered the possibilities of this proposal and has adopted a resolution urging all concerned to coöperate to the fullest extent in bringing about complete interchangeability of removable lighting fixtures. The resolution lays particular stress on the standardization of the electric attachments and other devices in the early stages of this development.

Standard Tables for Refrigerants

Intimately connected with the work of the A.S.M.E. Committee on a Standard Tonnage Basis for Refrigeration, is the suggestion of its chairman, F. E. Matthews, that the tables which record the physical properties of the various refrigerants be standardized as to the data given and the form and the arrangement of the tables.

Engineers now have available a number of tables giving the physical properties of the saturated vapors of water, ammonia, carbon dioxide, sulphur dioxide, methyl chloride, ethyl chloride, and other media which have been employed or proposed as refrigerants. No two of these tables, it is thought, include exactly the same kind of data arranged in the same order under any uniform system of captions and symbols.

The United States Bureau of Standards is now formulating a table of the properties of ammonia in the saturated and superheated regions. The table covering the saturated region has already been submitted in a tentative form to the American Society of Refrigerating Engineers. Since it is through the direct efforts of that society that funds are being provided for the work of making the final observations and computations necessary to complete these ammonia tables, it may be assumed that the tables will be presented in the form that will be most convenient for the use of refrigerating engineers, provided such form can be determined in advance. The present time, therefore, seems most propitious to invite suggestions from engineers and others in an effort to arrive at the most practical form.

To precipitate discussion on this subject we print below a list of ten column headings which are suggested for the proposed standard tables of physical properties of vapors. The tentative report of the Bureau of Standards referred to, which was printed in the January 18 issue of *Power*, contains ten columns of data. Of the headings listed below, columns 1, 3, 7, 4, 5, 6, 9, and 10 are there employed in the order indicated. In addition to these the Bureau of Standards' table records the Specific Volume of Liquid and the Entropy of Vaporization. It omits, however, Gage Pressure (col. 2) and Weight of Liquid (col. 8).

1 Temperature, deg. fahr. (t)
2 Gage Pressure, lb. per sq. in. (?)
3 Absolute Pressure, lb. per sq. in. (P_1)
4 Total Heat of Liquid above (—) 40 deg. fahr. and deg. cent., B.t.u. (q')
5 Latent Heat of Vaporization, B.t.u. (r)
6 Total Heat of Vapor above (—) 40 deg. fahr. and deg. cent., B.t.u. (i)
7 Specific Volume of Vapor, cu. ft. per lb. (V'')
8 Weight of Liquid, lb. per cu. ft. (?)
9 Entropy—Liquid (s')
10 Entropy—Vapor (?)

The general confusion existing regarding symbols for these quantities is a matter which should also be cleared up if possible at this time. If the symbols adopted could be international standards the results would be well worth striving for. To that end the widest publicity and freest comment are hoped for.

It is probable that differences of opinion will be expressed concerning the inclusion of columns 2, 3, 9 and 10 in a table designed for the convenient use of the operating refrigerating engineer. The questions which naturally arise can be stated as follows:

1 Are all ten columns listed necessary for a handy working table?
2 What substitutions or additions should be made?
3 Should Gage Pressure (column 2) be included?
4 Should the two Entropy columns be retained?
5 What standard symbols should be employed for the quantities listed?

Answers to these questions and written discussion covering other points to be considered in the development of standard tables of physical properties of refrigerants will be given careful attention if addressed the A.S.M.E. Secretary of Standards and Technical Committees.

Automobile Headlighting Specifications Submitted for Approval

The Illuminating Engineering Society has submitted its Automobile Headlighting Specifications to the American Engineering Standards Committee for approval. These specifications are submitted in accordance with the special provision in the procedure of the Committee, under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

The specifications have been adopted in their essential details by the states of Wisconsin, Connecticut and Maryland, and by the Province of Ontario, and have been endorsed by the Standards Committee of the Society of Automotive Engineers; by the International Traffic Officers' Association, and by the conference committee on Uniform Vehicle Laws, representing some 30 different organizations, under the auspices of the National Safety Council.

The American Engineering Standards Committee would be very glad to learn from those interested of the extent to which they make use of these specifications, and to receive any other information regarding the specifications in meeting the needs of the industry.

The Headlighting Specifications of the Illuminating Engineering Society may be found in the Transactions of the Society, Vol. XV, No. 4, June 10, 1920. Copies may also be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York.

At a meeting in London on April 25, of the executive secretaries of the standards associations of the principle commercial countries of the world, Dr. Paul G. Agnew, Secretary of the American Engineering Standards Committee, represented this country. His plans include visits to Belgium, France, Sweden, Switzerland, and Czecho-Slovakia to exchange general information on standardization projects, and to establish more intimate relationship with the standardization bodies of these countries.

LIBRARY NOTES AND BOOK REVIEWS

Belts for Power Transmission. By W. G. Dunkley. Sir Isaac Pitman & Sons, Ltd. (Pitman's technical primer series). Boards, 4 x 7 in., 104 pp., diagram, 7 x 4 in., boards, $1.

This is a small volume, for students and designers, presenting and discussing the factors and considerations involved in belt driving. Tables of use to designers are included.

The Boiler Book. Compiled by H. E. Dart. Published by the Hartford Steam Boiler Inspection and Insurance Co., Hartford, 1920. Paper, 7 × 10 in., 65 pp., 20 illus., $1.50.

This book, which is a novel and useful addition to the published works on boiler practice, is a collection of formulas, data and general information of great value to all having to do with the design, installation, operation and maintenance of steam boilers of all kinds. In accordance with the established practice of the Hartford Steam Boiler Inspection and Insurance Co., all drawings, tables and other data included are in full accordance with the provisions of the A.S.M.E. Boiler Code. The book is published in loose-leaf form and contains a copious index. The illustrations are in the form of blueprints.

Compressed Air. By Theodore Simons. Second edition. McGraw Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 173 pp., illus., tables, $2.

This treatise is intended to give the student such an insight into the natural laws and physical principles underlying the production, transmission and use of compressed air, as will enable him to comprehend the operation of the various appliances used for this purpose and to judge of their merit. The present edition has been carefully revised and partly rewritten.

Copper Refining. By Lawrence Addicks. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 211 pp., illus., tables, $3.

Electrolytic copper refining was for so many years conducted under conditions of strict commercial secrecy that but little has been published regarding the principles of operation, as distinct from descriptions of individual plants. This little book, comprising a series of articles, each dealing with one of the problems of refining, which originally appeared in *Chemical and Metallurgical Engineering*, is almost entirely a record of the author's personal experience.

The Dynamics of the Airplane. By Kenneth P. Williams. John Wiley & Sons., Inc, New York, 1921. (Mathematical monographs, 21.) Cloth, 6 × 9 in., 138 pp., diagrams, $2.50.

This book, intended for students of mathematics and physics who are attracted by the dynamical aspect of aviation, grew out of a course of lectures on aerodynamics given by Professor Marchis, at the University of Paris in 1919. The treatment is elementary for the most part.

Electric Welding. By Ethan Viall. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 417 pp., illus., $4.

This volume is a compilation of the available literature on electric welding, selected and arranged by an experienced editor. It forms a convenient source of information on present methods, apparatus and applications.

Elements of Fuel-Oil and Steam Engineering. By Robert Sibley and C. H. Delany. Second edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 466 pp., illus., tables, $5.

The theme of this book is a study of fuel-oil power-plant operation and the use of evaporative tests to increase their efficiency. It includes an exposition of the elementary laws of steam engineering, the use of oil for fuel in the modern power plant, and the testing of oil-fired boilers. This edition has been rewritten, and much new material added.

Employee Training. By John Van Liew Morris. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 8 in., 311 pp., $3.

This work presents the results of an inquiry into the program and organization machinery being utilized by various manufacturing concerns to train their own workers, both by apprenticeship courses and by vocational training. It shows industry's own solution of its training problems and should be suggestive to manufacturers as a collection of tried methods.

Hendricks' Commercial Register of the United States. Twenty-ninth annual edition (1921). S. E. Hendricks Co., Inc., New York, 1921. Cloth, 8 × 10 in., 2572 pp., $12.50.

This well-known classified directory of manufacturers and dealers in supplies used by engineering firms has been carefully revised, new firms have been added, and those no longer extant have been eliminated. As in previous issues, the directory includes a classified list of dealers, an alphabetical list, an index of trade names, and an index of commodities.

Installing Management in Woodworking Plants. By Carle M. Bigelow. The Engineering Magazine Co., New York, 1920. Cloth, 6 × 9 in., 323 pp., illus., $5.00.

The author's purpose has been twofold; first, to express in a general way his ideas as to the application of the principles of scientific management to an industry, and second, to outline in detail their application to the specific problems of the woodworking industry.

Kinematics and Kinetics of Machinery; a Text Book for Colleges and Technical Schools. By John A. Dent and Arthur C. Harper. John Wiley & Sons, Inc., New York, 1921. Cloth, 6 × 9 in., 383 pp., illus., tables, $3.50.

This treatise gives systematic methods, mainly graphical, of determining velocities, accelerations and inertia forces which can be applied to practically all mechanisms. The text is based upon notes prepared by Professors G. A. Goodenough and F. B. Seeley, and used for instruction at the University of Illinois. These notes have been revised and extended by the authors.

The Locomotive Up to Date. By Chas. McShane. Revised by author. Griffin & Winters, Chicago, 1920. Cloth, 6 × 9 in., 893 pp., illus.' plates, $5.

The first edition of this book appeared over twenty years ago, and found popularity as a clear explanation of the construction, operation and repair of the locomotive, suited to the needs of railway men without special engineering knowledge. The present edition has been revised, enlarged, and partly rewritten, to meet modern conditions.

The Manufacture of Pulp and Paper. Vol. 1. Arithmetic, Elementary Applied Mathematics, How to Read Drawings, Elements of Physics. By J. J. Clark. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 132 pp., illus, $5.00.

This book is the first of a series of five volumes, prepared under the auspices of the Canadian Pulp and Paper Association and the Technical Association of the Pulp and Paper Industry, which is intended to form a suitable course of study in the fundamentals of mathematics and science and the manufacturing operations involved in modern pulp and paper practice. The treatment is simple, as the books are intended for self-instruction, as well as for classroom use.

Marine Engineering. By A. E. Tompkins. Fifth edition, revised. Macmillan and Co., Ltd., London, 1921. Cloth, 6 × 9 in., 888 pp., illus., $11.25.

An extensive one-volume textbook covering a sound course in marine engineering, treating all the subjects usually included in that term. This edition has been extensively revised and many chapters have been rewritten. Much obsolete matter has been omitted and mercantile practice has been considered more fully than before.

Mechanical World Year Book, 1921. Manchester and London, Emmott & Co., Ltd. Cloth, 4 × 6 in., 318 pp., illus., 2s. 6d.

This inexpensive annual is intended as a convenient pocket

(Continued on page 359)

AN INVESTIGATION OF OXY-ACETYLENE WELDING AND CUTTING BLOWPIPES

(*Continued from page 310*)

It was evident that further information was essential if a satisfactory analysis of welding-blowpipe performance was to be made. The greatest discrepancy from what was expected appeared to be in the high gas ratios obtained, and the first attempt to answer the problem was made by a study of gas-ratio phenomena. This seemed particularly desirable as it has been very firmly held by almost all authorities that good welding cannot be done with blowpipes having a high gas ratio.

An extensive series of supplementary gas-ratio tests was accordingly carried out. As a result of these tests a phenomenon of exceeding interest was developed, and gas ratios approaching very nearly the theoretical value obtained. The results obtained accounted partly for the quality of the welding work secured. In some respects, though, they added increased confusion by lack of consistency.

In further study of the data secured by the prescribed tests it was noticed that blowpipes that seemed especially susceptible to flashback were those in which the oxygen was delivered to the blowpipe at a pressure very much in excess of that at which the acetylene was delivered. It was further noticed, that even among such blowpipes, inconsistencies appeared. Critical examination of tip design in these blowpipes suggested a possible explanation. On this basis another series of supplementary tests was made, from the results of which data were secured that clearly explain the cause of flashback phenomena.

The logical continuance of the theory evolved for flashback leads directly to the question of safety in operation and correct gas ratio and will explain, in large part, the reason for so large a proportion of oxy-acetylene welds being of inferior grade.

The essential qualifications for a satisfactory welding blowpipe as enumerated above are therefore very intimately connected with the conditions governing flashback. It seems desirable, then, to begin the discussion of the results obtained in the tests of the investigation by the critical analysis of the conditions conducive to the development of flashbacks in welding blowpipes.

Any obstruction to the gaseous flow at the tip exit produces a back pressure that pushes back within the tip in the most direct line. An acetylene passage entering the oxygen tube at right angles has its flow cut off very quickly, especially when the oxygen pressure is much higher than the acetylene pressure and the point of admission of the oxygen is as it is in most of the tip designs beyond the point of admission of the acetylene. The checking of the acetylene flow is further assisted by the collapse of the partial vacuum and the infiltration of oxygen within the acetylene passage when the developed back pressure retards the aspirating effect existent in all tips of present design. Further, as Fig. 7 (p. 309) shows, in practically all designs the contracted throat is used in the acetylene passage, with the result that even in those blowpipes in which the acetylene is delivered at excess pressure or in which both gases are supposed to operate under equal pressures, a section of reduced or unbalanced pressure exists which is readily affected by the back pressure caused by obstructions at the tip end. It is perceived that under such conditions there are constant changes within the blowpipe tip in the desired one-to-one volume ratio of gases, with the result that a mixture leaner in acetylene is developed and flashback takes place.

The results of a series of gas-ratio tests, especially those run with diffraction gratings to examine the flame spectroscopically, are shown in Table 1 (p. 309), and it will be noticed that the use of gratings shows very marked changes in values. This table shows that practically any of the present blowpipes can be made to produce a neutral flame and burn equal volumes of oxygen and acetylene if the flame can burn undisturbed in the air. But, as indicated above, none of them can maintain such a flame during the welding process.

Referring to the strengths of the welds executed during these tests (see Table 2), it will be seen that the second plate welded during each test invariably showed the higher strength. It will be remembered that to counteract the effects of expansion the 2-ft. test welds were made by welding two 1-ft. lengths of plate. These plates were supported on a heavy iron casting that contained a channel throughout its length parallel to and directly under the line of welds. This channel caused the flame of the blowpipe to return under the plates being welded and thus preheated to some extent the second plate. Further, it caused a decided heating of the near end of the base casting. The explanation for the higher strength shown by the second plate probably lies in the more uniform preheating of the second plate and the greater annealing effect produced by the heated base casting, the latter causing a release of the tensile strains resulting from the contraction of the metal along the line of the weld.

The average strengths and average included angle of bend are given in the above-mentioned table (Table 2) for what they are worth. It is very probable in the light of present knowledge of the requirements of blowpipe design that some new ideas will be forthcoming concerning the average strength of oxy-acetylene welds. Finally in Fig. 8 are exhibited photomicrographs showing the effect upon the grain structure of the material, in this case mild steel, of the autogenous welding process, effects not necessarily detrimental when properly performed, but, as exhibited by the photomicrographs, instructive.

BOOK NOTES

(*Continued from page 358*)

reference book for mechanical engineers and shop superintendents. The most-used data are given on steam engines and boilers, gas and oil engines, gas producers, the properties of metals, structural iron and steel work, toothed gearing, bearings, belting, friction and lubrication, steam fitting, screws and similar subjects. A buyer's directory is included.

A Treatise on Airscrews. By Whyrill E. Park. E. P. Dutton & Co., New York, 1921. (The Directly-Useful Technical Series). Cloth, 6 × 9 in., 308 pp., illus., diagrams, charts, tables, $8.

This book considers the problems of airscrew-propeller design and construction from the viewpoint of designers, draftsmen and others engaged in the practical design of aircraft. In general, it follows the methods developed by Lang Propeller, Ltd. It is intended to supply directly useful information, accompanied by a proper amount of scientific explanation. The theory presented is one that has proved convenient for drafting-room use.

A Treatise on Reinforced Concrete. By W. Noble Twelvetrees. Sir Isaac Pitman & Sons, Ltd., New York, 1920. Cloth, 6 × 8 in., 264 pp., plates, $7.50.

In this volume the author has endeavored to set forth as clearly as possible the general characteristics and distinctive properties of reinforced concrete and its constituents, to discuss in a systematic manner the principles underlying the design of homogeneous members, and to show how these principles may be applied to the evolution of formulas for the design of reinforced-concrete members of different classes. It is restricted to fundamental principles and presents a complete series of formulas for the principal classes of members employed in engineering and building construction. The book is the first to employ the standard notation adopted by the Concrete Institute. This notation is given in full, with an explanatory foreword.

Schmiede und Schmiede-Technik. By C. Oetling. Band 1. R. Oldenbourg, München und Berlin, 1920. Paper, 8 × 11 in., 621 pp., illus., diagrams, 90 Marks.

This volume is the outgrowth of a work submitted in 1911 to the Verein deutscher Maschinen-Ingenieure in competition for a prize offered for systematic study of the value of new methods and apparatus for forging. The report has been expanded, at the request of the prize committee, into an exhaustive examination of forge-shop methods. The present volume, the first of two, was printed in 1914, but has only now been published. It discusses fuels, heating furnaces, methods of controlling heat, forging hammers and presses, shears, saws, welding, measuring instruments, cranes and conveyors.

THE ENGINEERING INDEX

(Registered U. S. Patent Off.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Dust Explosions. Some Electrical Causes of Dust Explosions, David J. Price. Jl. Electricity & Western Industry, vol. 46, no. 5, Mar. 1, 1921, pp. 240–242, 3 figs. Experiments and observations revealed that dust explosions may be produced by electrical bulbs broken in dust clouds, dust collecting on electrical lamps and static electricity produced by friction of finely divided materials.

AERODYNAMICS

Laws. Aerodynamics at Very High Speed, A. Guidoni. Aerial Age, vol. 13, no. 2, Mar. 21, 1921, pp. 31–32, 4 figs. Aerodynamic laws governing design of aeroplanes for extra fast service.

AEROPLANE ENGINES

Compression Ratio and Thermal Efficiency. Compression Ratio and Thermal Efficiency of Airplane Engines, S. W. Sparrow. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 266–268 and 281, 6 figs. Tests conducted by National Advisory Comm. for Aeronautics. Results showed that efficiency of combustion is influenced but little by change in density so long as temperature is maintained constant.

Development. Some Possible Lines of Development in Aircraft Engines, H. R. Ricardo. Aeronautical Jl., vol. 25, no. 123, Mar. 1921, pp. 130–145, 20 figs. Employment of kerosene mixtures as fuel, limiting size of cylinder, and possibilities of working with short compression and long expansion stroke are among chief possibilities considered.

Efficiencies. Aero Engine Efficiencies, A. H. Gibson. Aviation, vol. 10, no. 8, Feb. 21, 1921, pp. 238–240, 2 figs. Experimental examination of manner in which mechanical, volumetric and thermal efficiencies are effected by design and conditions of operation of engine. (Abstract.) Paper read before Royal Aeronautical Soc.

See also Thermal Efficiency.

Fuel-Feed Systems. Fuel Feed Systems for Airplanes, L. B. Lent. Aviation, vol. 10, no. 10, Mar. 7, 1921, pp. 294–298, 6 figs. Developments in planes operated by U. S. Air Mail Service. Critical study and suggestions in regard to improvements.

Mounting. The Installment of an Aeroplane Engine, A. J. Rowledge. Aeronautical Jl., vol. 25, no. 123, Mar. 1921, pp. 145–158 and (discussion) pp. 158–165, 9 figs. Typical mountings of aeroplane engines. Mounting with a view to simplifying attention of engine and making important parts accessible for repair and inspection.

Napier Lion. Some New Napier "Lion" Necessities and "The Cub." Flight, vol. 13, no. 6, Feb. 10, 1921, pp. 93–95, 6 figs. Accessory details on Napier "Lion" such as armouring of ignition cables with material that earths induced currents due to extreme high voltage, brass distributor shielding, and cut-out cock in return lead to pump from carburetor water-jacketing for flight in tropical climates.

Packard. An American Engine for Altitude Work, Jesse G. Vincent. Aviation, vol. 10, no. 9, Feb. 28, 1921, pp. 260–262, 5 figs. Packard type designed for work in high altitudes and recently completed for U. S. Army Air Service.

Special Packard Aero Engine for Altitude Work, Jesse G. Vincent. Aerial Age, vol. 12, no. 25, Feb. 28, 1921, pp. 631–633 and 643, 7 figs. Compression ratio is $6^1/_2$ to 1 and cylinder displacement 1237 cu. in. Throttle is provided as safety stop which is thrown off when altitude of 5000 ft. has been reached.

Panhard-Levassor. Panhard-Levassor 12-Cylinder Airplane Motor, F. P. Mann. Gas Engine, vol. 23, no. 3, Mar. 1921, pp. 75–76, 2 figs. Engine is V-type and develops 240 hp. at speed of 1350 r.p.m.

Steadiness Factor. The Steadiness Factor in Engine Sets, W. Margoulis. Aerial Age, vol. 12, no. 26, Mar. 7, 1921, pp. 659–661, 2 figs. Derivation of formula. Comparison of steadiness factor of engine sets and of engines having constant brake torque as function of speed rotation.

Thermal Efficiency. Means of Materially Increasing Thermal Efficiency, H. R. Ricardo. Automotive Industries, vol. 44, no. 8, Feb. 24, 1921, pp. 456–462, 10 figs. Use of stratified charges and other means for improving efficiency are outlined. Paper read before Royal Aeronautical Soc. of Great Britain.

See also Compression Ratio.

AEROPLANE PROPELLERS

Parachutal Uses. Study of the Resistance Furnished by an Aeroplane Propeller Rotating in a Current of Air (Étude sur la résistance fournie par les hélices tournant dans un courant d'air), M. Lamé. Aérophile, vol. 29, nos. 1–2, Jan. 1–15, 1921, pp. 5–7, 4 figs. Experiments were performed at Eiffel laboratory, Paris, to determine parachutal value of supporting propellers. Empirical formulas and laws are formulated from results obtained.

Performance. Experimental Research on Air Propellers—IV, W. F. Durand and E. P. Lesley. Nat. Advisory Committee for Aeronautics, no. 109, 1921, 11 pp., 12 figs. Investigations of performance of aeroplane propellers.

AEROPLANES

Design. Loads and Calculations of Army Aeroplanes, Ing. Stelmachowski. Aerial Age, vol. 13, no. 1, Mar. 14, 1921, pp. 9–11, 3 figs. Standards for calculation of aeroplane structures. Translated from Technische Berichte.

Downwash. The Determination of Downwash, Walter S. Diehl. Aerial Age, vol. 12, no. 26, Mar. 7, 1921, pp. 655–656, 6 figs. Derivation of downwash formula from Göttingen theoretical and Nat. Physical Laboratory empirical formulas. Technical note of Nat. Advisory Committee for Aeronautics.

Helicopters. See HELICOPTERS.

Manufacture. Details of Large Airplane Work. Am. Mach., vol. 54, no. 9, Mar. 3, 1921, pp. 357–359, 8 figs. Fixtures used in wing construction. Increasing application of metal framing. Installing motors in planes. Methods of assembling fuselages.

Speed Measurement. Note on Measurement of Speed of Airplanes, S. Herbert Anderson. Aviation, vol. 10, no. 8, Feb. 21, 1921, pp. 233–234, 2 figs. Methods for finding true airspeed of airplane when there is wind, from data secured by timed flights over measured course.

Stabilizers. Visible Stabilization of Aeroplanes (Sichtbare Stabilisierung von Luftfahrzeugen), Friedrich Budig. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 2, Jan. 31, 1921, pp. 22–26, 5 figs. Auxiliary supporting plane, attachment indicating course of flight to aeroplane passengers as well as to pilot.

Wings. Some Experiments on Thick Wings with Flaps, C. D. Hanscom. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 271–276, 31 figs. Tests made in wind tunnel of Mass. Inst. of Technology with different models and designs of wings. The Handley-Page Aeroplane Wings, F. Handley Page. Engineering, vol. 111, no. 2879, Mar. 4, 1921, pp. 274–276, 21 figs. Paper read before Royal Aeronautical Soc.

The Handley Page Wing, F. Handley Page. Aeronautics, vol. 20, no. 384, 385 and 386, Feb. 24, Mar. 3 and 10, 1921, pp. 128–130, 16 figs., 153–154, 10 figs., and 167–168, 3 figs. Also Flight, vol. 13, no. 8, Feb. 24, 1921, pp. 130–137, 29 figs; Aerial Age, vol. 13, no. 2, Mar. 21, 1921, pp. 37–38, 16 figs. Record of experimental work carried out with a view to overcoming phenomenon of "burbling." Experiments with slotted aerofoil. Paper read before Royal Aeronautical Soc.

[See also AIRCRAFT, Development during War.]

AIRCRAFT

Developments During War. The Evolution of Aeronautics During the War (L'evolution de l'aéronautique pendant la guerre), M. Renard. Bulletin de la Société d'Encouragement pour l'Industrie nationale, vol. 133, no. 1, Jan. 1921, pp. 21–51, 9 figs. Developments in design and construction of airships and aeroplanes.

German Giant. Development of Giant Aircraft in Germany. Aeronautical Jl, vol. 25, nos. 122–123, Feb. and Mar. 1921, pp. 100–116, 3 figs., and 166–188, 5 figs. Comparative study of types developed during the war. Economics of giant machine from military point of view. Visualization of best type from records of performance of giant German machines during war.

Maintenance. Ground Engineering, H. W. S. Outram. Aeronautics, vol. 20, no. 392, Feb. 10, 1921, pp. 96–98. British air navigation regulations for maintenance of aircraft at airdrome. Paper read before Royal Aeronautical Soc.

AIRCRAFT CONSTRUCTION MATERIALS

Lugs. Design of Standard Lugs, B. C. Boulton. Aerial Age, vol. 12, no. 25, Feb. 28, 1921, pp. 634–637, 8 figs. Summary of work done to determine correct design for standard lugs, notably by Material Section of McCook Field.

Plywood. See PLYWOOD.

AIRSHIPS

Mooring and Handling. A Stabilizing Raft for Mooring Airships Over the Sea, P. H. Sumner. Aeronautics, vol. 20, no. 382, Feb. 10, 1921, pp. 99, 4 figs. Raft fitted with stabilizing planes. Airship Mooring and Handling. Aeronautical Jl., vol. 25, no. 122, Feb. 1921, pp. 71–84 and (discussion) pp. 85–93, 13 figs. Survey of developments in Great Britain.

Note on the Mooring of Airships by "Free" Wire Systems, R. A. Frazer and L. F. G. Simmons. Aeronautical Jl., vol. 25, no. 122, Feb. 1921, pp. 94–99, 6 figs. Experiments conducted at Nat. Physical Laboratory, England.

Piloting. Airship Piloting. Aeronautical Jl., vol. 25, no. 122, Feb. 1921, pp. 47–71, 5 figs. Controllability under severe weather conditions. Technique of piloting. Methods of aerial navigation.

[See also AIRCRAFT, Development during War; HANGARS.]

ALCOHOL

Industrial. A New Alcohol from Oil—Not Potable. Compressed Air Mag., vol. 26, no. 3, Mar. 1921, pp. 10.005. "Petrohol" manufactured by the Standard Oil Co. of New Jersey from gases given off in cracking process of refining crude oil.

Alcohol Production from Molasses, George M. Appell. Chem. Age (N. Y.), vol. 92, no. 2, Feb. 1921, pp. 53–57, 1 fig. Diagram of classes of raw material and procedure of treatment for production of alcohol.

Industrial Alcohol Status in Canada. Can. Chem. & Metallurgy, vol. 5, no. 3, Mar. 1921, pp. 79–81. Legislation concerning manufacture of industrial alcohol.

Manufacture of Ethyl Alcohol from Wood Waste, E. C. Sherrard. Chem. Age (N. Y.), vol. 29, no. 2, Feb. 1921, pp. 76–79. Plant requirements.

ALLOYS

Standardization. Canadian Mechanical Standards Paper, vol. 27, no. 26, Mar. 2, 1921, pp. 21–27 and 40, 12 figs. Report of Committee on Mechanical Standards of Canadian Paper & Pulp Assn. on standardization of metal alloys used in machinery employed for manufacture of paper. Investigations were conducted on acid-resisting bronze, properties of copper-tin-lead bronze, and antimonial lead, and also on a number of bearing metals.

ALUMINUM

Castings. Machining a Combined Bearing Housing and Control Bracket. Eng. Production, vol. 2, no. 20, Feb. 17, 1921, pp. 219–223, 13 figs. Quantity production of aluminum castings for automotive bearing housing and control bracket.

Conductors. The Use of Aluminum Conductors on Transmission Lines, Theodore Varney. Elec. News, vol. 30, no. 5, Mar. 1, 1921, pp. 30–34, 6 figs. Relative merits of steel-cored aluminum and copper conductors on level and rough courses discussed before Toronto Section, Am. Inst. Elec. Engrs.

Ingots, Piping of. Causes of Piping in Aluminum Ingots, Junius David Edwards and Harold T. Gammon. Chem. & Metallurgical Eng., vol. 24, no. 8, Feb. 23, 1921, pp. 338–340, 12 figs. Measurements of piping and solidification shrinkage show that volume of pipe is dependent on four or even more definite factors, and that it is not specific property of metal or alloy.

Nickel Plating of. Nickel Plating of Aluminum (Le nickelage de l'aluminium), Léon Guillet. Mémoires et Compte rendu des Travaux de la Société des Ingénieurs civils de France, vol. 73, nos. 7, 8 and 9, July–Sept. 1920, pp. 453–470, 10 figs. Procedure.

Sheet. Stages in the Recrystallization of Aluminum Sheet on Heating: With a Note on the Birth of Crystals in Strained Metals and Alloys, H. C. H. Carpenter and Constance F. Elam. Advance Paper, no. 1, meeting of Inst. Metals, Mar. 9, 1921, 22 pp., 38 figs. Results of experiments.

The Recrystallization of Aluminium on Heating, H. C. H. Carpenter and Constance F. Elam. Engineering, vol. 111, no. 2880, Mar. 11, 1921, pp. 302–307, 38 figs. Stages in recrystallization of aluminum sheet on heating, with note on birth of crystals in strained metals and alloys. Interpretation of photomicrographs. Paper read before Inst. of Metals.

Soldering. A Great Progress in the History of Aluminum (Un grand progrès dans l'histoire de l'aluminium), Ch. Faroux. Vie automobile, vol. 17, no. 724, Feb. 25, 1921, pp. 66–67, 2 figs. Soldering aluminum by means of stagneol, an alloy which permits soldering of aluminum in the same manner and with same instruments as for tin soldering.

ALUMINUM ALLOYS

Castings. Analyze Loss in Aluminum Shops—VI, Robt. J. Anderson. Foundry, vol. 49, no. 5, Mar. 1, 1921, pp. 188–191. Reasons for losses in production of aluminum alloys and castings.

Blowholes, Porosity, and Unsoundness in Aluminium Alloy Castings, Robert J. Anderson. Foundry Trade Jl., vol. 23, no. 237, Mar. 3, 1921, pp. 205–207, 8 figs. Data on six heats made on aluminum alloy, no. 12 (92 per cent aluminum and 8 per cent copper), to determine temperature effects.

AMMONIA COMPRESSORS

Mean Effective Pressures. Mean Effective Pressures John E. Starr. Refrigerating World, vol. 56, no. 3, Mar. 1921, pp. 11–12. Tables of multipliers of back pressure and temperature to obtain mean effective pressure and final gas temperatures in compressing gases.

APPRENTICES, TRAINING OF

Systems. Programs of Apprenticeship and Special Training in Representative Corporations—XI, J. V. L. Morris. Am. Mach., vol. 54, no. 12, Mar. 24, 1921, pp. 505–507, 3 figs. Practice of Goodyear Tire & Rubber Co., Akron, Ohio. Instruction of many kinds is provided by industrial university.

ARTILLERY

Matériel Developments. The Development of Artillery Matériel, G. F. Jenks. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 167–172, 13 figs. Consideration of artillery-matériel development before war and effect of war upon it, both in U. S. and European countries. Efforts since war have been devoted chiefly to developments of pieces of greater range, greater elevation and greater mobility. Survey of developments of anti-aircraft matériel and coast-defense work is included.

AUTOMOBILE ENGINES

Diesel Type. Diesel Type of Engine for Motor Vehicle Work. Automotive Industries, vol. 44, no. 9, Mar. 3, 1921, pp. 501–509. 2 figs. Built by Deutsche Automobil Constructions Gesellschaft. Engine has two pistons in same cylinder and works on two-stroke cycle. Injection results from explosion in ignition chamber connected with combustion chamber by narrow passage.

Manifold. The L.O.A. Fuel Economiser. Autocar, vol. 46, no. 1321, Feb. 12, 1921, p. 295, 2 figs. Patented manifold where fuel charge is heated by exhaust gases.

Manifolds, Intake Flow. Intake Flow in Manifolds and Cylinders, P. S. Tice. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 282–284, 9 figs. Records of photographic measurements.

Manufacture. Special Machines and Tools in a Motor-Car Works. Machy. (London), vol. 17, no. 438, Feb. 17, 1921, pp. 609–612, 6 figs. Equipment used for milling crankcases, boring and reaming crankshaft and camshaft bearings and other operations.

Packard Fuelizer. The Packard Fuelizer, L. M. Woolson. Jl Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 240–248, 6 figs. Device used as substitute for hot-spot.

Radiators. The Manufacture of Radiator Gills, A. W. Allen. Machy. (London), vol. 17, no. 438, Feb. 17, 1921, pp. 606–607, 4 figs. Types of radiator gills. Tools used in their manufacture.

Spring. Rigid Construction and Clear Appearance Feature of New Engine, J. Edward Schipper. Automotive Industries, vol. 44, no. 9, Mar. 3, 1921, pp. 493–494, 3 figs. Four-cylinder engine designed by Frank S. Spring of Detroit. High power output and good fuel economy are claimed for engine.

Valves. The Graphical Analysis of Valve Gear. Automobile Engr., vol. 11, no. 147, Feb. 1921, pp. 66–67, 4 figs. Simplified method of investigation.

AUTOMOBILE FUELS

Alcohol. Possibilities of Alcohol for Fuel, A. H. Gilbert. Agricultural Eng., vol. 2, no. 1, Jan. 1921, pp. 5–6. Summary of research conducted by technical institutions and government agencies. Committee report presented at meeting of Am. Soc. of Agricultural Engrs.

[See also ALCOHOL, Industrial.]

Characteristics. The Character of Various Fuels for Internal Combustion Engines,—I. H. T. Tizard and D. R. Pye. Automobile Engr., vol. 11, no. 147, Feb. 1921, pp. 55–57. Theoretical investigation of influence of specific heat and dissociation of working fluid, made preliminary to experimental investigation conducted by H. R. Ricardo.

Tests. The Character of Various Fuels for Internal Combustion Engines,—II H. T. Tizard and D. R. Pye. Automobile Engr., vol. 11, no. 148, Mar. 1921, pp. 98–101, 2 figs. Influence of specific heat and dissociation of working fluid. Calculation of maximum temperature allowing for dissociation.

The Influence of Various Fuels on the Performance of Internal Combustion Engines—II, H R. Ricardo. Automobile Engr., vol. 11, no. 148, Mar. 1921, pp. 92–97, 7 figs. Experimental investigation into behavior of various automobile fuels. Graphs are given which show relation between air cycle standard efficiency and compression ratio, also variation in mean effective pressure and thermal efficiency with different compression ratios for fuel detonating normally at compression of 5 to 1.

Vegetable Oils. Vegetable Oils as Fuel for Internal Combustion Engines Engr., vol. 121, no. 3402, Mar. 11, 1921, pp. 255–256. Experiments on utilization of palm oil as engine fuel. Reports submitted to Assn. for the Improvement of Belgian Colonies.

[See also ALCOHOL; BENZOL; GASOLINE.]

AUTOMOBILES

Axles. Stub-Axle Stresses, J. L. Napier. Automobile Engr., vol. 11, no. 148, Mar. 1921, pp. 82–83, 2 figs. Study on stresses and their relation to side-slip.

Design. Need for Greater Service Accessibility in Car Design, T. F. Cullen. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 257–264, 13 figs. Survey of automobiles in regard to accessibility of parts for repairs. Suggestions for increasing accessibility.

Why American, British and Continental Car Designs Differ, M. Olley. Automotive Industries, vol. 44, no. 10, Mar. 10, 1921, pp. 547–553. Writer discusses effect of customs, climate, road conditions, taxes, operating costs, size of industry, point of view and competition upon size, cost, appearance and design of passenger cars. Motoring here is characterized as transportation, while in Europe spirit of adventure still dominates. Considers American braking systems defective.

Landing Gear. The Klemin Amphibious Gear, Donald W. McIlhiney. Aviation, vol. 10, no. 9, Feb. 28, 1921, pp. 271–272, 2 figs. Landing gear composed of ordinary wheel structure and tail skid, both of these parts being retractable.

Manufacture. A Modern Chassis Assembly Plant. Automobile Engr., vol. 11, no. 148, Mar. 1921, pp. 102–104, 6 figs. Methods of Standard Motor Co., England.

Methods in a Continental Works. Eng. Production, vol. 11, no. 19, Feb. 10, 1921, pp. 195–203, 32 figs. Belgian factory manufacturing motor cars, motorcycles, small arms, small-caliber ammunition and pedal cycles.

Radiators, Alcohol-Water Mixtures for. Report Giving Tables Showing the Freezing Points and Specific Gravity of Alcohol-Water Mixtures. Air Service Information Circular, vol. 12, no. 178, Jan. 20, 1921, 6 pp., 2 figs.

Transmissions. Developments in Transmission, S. Bramley-Moore. Automobile Engr., vol. 11, no. 147, Feb. 1921, pp. 70–75, 33 figs. Developments in clutch and gear-box design.

Gear Box vs. Electrical Transmission. Autocar, vol. 46, no. 1319, Jan. 29, 1921, pp. 189–192, 11 figs. Relative merits of various transmission systems. It is claimed that electric transmission affords greater comfort and longer tire life. Curves are given showing comparative efficiencies of electrical and other methods of power transmission.

Wheel Hubs, Standardization. Move to Unify All Interest in Hub Standardization Work, J. Edward Schipper. Automotive Industries, vol. 44, no. 11, Mar. 17, 1921, pp. 592–594, 1 fig. Standardization for ball-bearing front-axle hubs proposed by representatives of ball-bearing manufacturers at joint meeting with Soc. Automotive Engrs.

AVIATION

Aerial Transportation. Aeroplane & Seaplane Transport Efficiency, H. White-Smith. Aeronautics, vol. 20, no. 385, Mar. 3, 1921, pp. 151–152. Mobility, safety, reliability and economy of working of aerial transportation. (To be continued.) Paper read at Olympia Efficiency Exhibition.

The Cost of Aerial Transportation (Die Kosten der Luftreise). Alexander Baumann. Zeit. fur Flugtechnik u. Motorluftschiffahrt, vol. 12, nos 2 and 3, Jan. 31 and Feb. 15, 1921, pp. 17–20 and 33–35. Points out that if air traffic is to become firmly established, the costs must be reduced. This is possible in a slight degree through constructive methods referred to, but in a far greater degree through establishment of effective traffic routes, proper emergency landings, etc.

Civil. America's First Model Airway. Aviation, vol. 10, no. 9, Feb. 28, 1921, pp. 267–270, 1 fig. Proposed model airway from Washington, D. C., to Dayton, Ohio.

Status of Commercial Aircraft Shown by Company Development. Automotive Industries, vol. 44, no. 10, Mar. 10, 1921, pp. 559–561. List of flying companies operating in U. S. There are 88 companies operating about 400 aircraft units.

The Operation of Civil Aircraft in Relation to the Constructor, H. White-Smith. Flying, vol. 10, no. 2, Mar. 1921, pp. 47–59. Costs of operating commercial air services. Present position of seaplanes, flying boats and amphibians.

U. S. Commercial Aircraft Companies. Aviation, vol. 10, no. 10, Mar. 7, 1921, pp. 299–301. List of commercial aircraft operating companies in the United States and Canada, with account of air port facilities and aircraft owned and rates of service.

Commercial. Norway's Experience of Commercial Aviation. Flight, vol. 13, no. 6, Feb. 10, 1921, pp. 96–97, 3 figs. Records of air service in Norway.

Winged Transportation, Ladislas d'Orcy. Sci. Am., vol. 124, no. 9, Feb. 26, 1921, pp. 168–169, 3 figs. Survey of commercial air service in U. S., Europe and South America. List of world's air transport services.

Soaring Flight. Soaring Flight, M. A. S. Riach. Aeronautics, vol. 20, nos. 383–384, Feb. 17 and 21. 1921, pp. 117–118, 7 figs., and 132–134, 1 fig. Study of forces acting.

B

BEARING METALS

See ALLOYS, Standardization.

BEARINGS, BALL

Housings. Manufacturing a Ball Bearing Housing Eng. Production, vol. 11, no. 19, Feb. 10, 1921, pp 180–184, 10 figs. Jigs and tools for manufacturing small ball-bearing housings in quantities.

BENZOL

Specifications. New Purity Standard for Benzole. Autocar, vol. 45, no. 1323, Feb. 26, 1921, pp. 369. Specifications adopted by British Eng. Standards Assn.

BLAST-FURNACE GAS

Cleaning Process. Recovery Process for Flue Dust, George B. Cramp. Blast Furnace & Steel Plant, vol 9, no. 3, Mar. 1921, pp. 198–202, 1 fig. Claims that first cost of direct-recovery plant is smaller than that of any other process, and also that operating expenses are very low.

Gas Balances. The Relative Distribution of Blast-Furnace Gases as Fundamental Basis of the Heat Economics of Mixed Steam and Gas Power Installations (Die bilanzmässige Verteilung der Gichtgase als Grundlage der Wärmewirtschaft gemischter Werke), G. Schulz. Stahl u. Eisen, vol. 41, no. 5, Feb. 3, 1921, pp. 145–149 and (discussion) pp. 149–150, 5 figs. Results of work of a special commission of engineers in drawing up a gas balance for blast-furnace gases.

Measurement. Measurement of Blast-Furnace Gas, D. L. Ward. Min. & Metallurgy, no. 170, Feb. 1921, pp. 33–34, 1 fig. Study to determine how much surplus power could be produced through proper utilization of entire gas flow from two furnace

stacks at Federal Furnace Plant, South Chicago, Ill., Method of measuring flow of gas.

BLAST FURNACES

Air Preheaters. Air Preheaters (Kritische Bemerkungen über Winderhitzer), Emil Wurmbach. Stahl u. Eisen, vol. 41, no. 3, Jan. 20, 1921, pp. 74–76, 1 fig. Critical discussion of heat transmission from the heating gas to the bricks and from these to the blast.

600-Ton New Blast Furnace Recently Completed. Iron Age, vol. 107, no. 9, Mar. 3, 1921, pp. 570–575, 7 figs. 600-ton furnace furnished with 92-ft. stack, 18-ft. hearth, 22-ft. 6-in. bosh and 16-ft. diameter stock line.

BOILER FEEDWATER

Treatment. Control of Salt Content in Boiler Water, Claude C. Brown. Power Plant Eng., vol. 25, no. 5, Mar. 1, 1921, pp. 264–266, 4 figs. Chart showing amount of blowdown necessary for varying degrees of salinity and varying boiler ratings.

Degassing and Purification of Boiler Feed Water, Paul Kestner. Engineering, vol. 111, no. 2880, Mar. 11, 1921, pp. 291. Process of continuous blowing down used in conjunction with hot purification. (Abstract.) Paper read before joint meeting of Instn. Mech. Engrs. and Soc. Chem. Industry.

Kestner Apparatus for Removal of Gases from Feedwater (L'appareil dégazeur Kestner), M. Perdrizet. Revue générale de l'Electricité, vol. 9, no. 6, Feb. 5, 1921, pp. 185–187, 4 figs. Mechanical and chemical degasification.

"Pure" Water for Locomotives, Paul M. LaBach. Ry. Rev., vol. 68, no. 12, Mar. 19, 1932, pp. 456–460. Suggestions in regard to making calculations involved in computing amount of ingredients to use in treatment processes.

BOILER INSPECTION

Legislation. Uniform Boiler Inspection Laws, C. O. Meyers. Power Plant Eng., vol. 25, no. 5, Mar. 1, 1921, pp. 288–289. Advantages sought and difficulties encountered in enforcement. Experience in Ohio.

BOILER OPERATION

Gas-Fired Boilers. Investigation of Gas-Fired Steam Plant, R. L. Ellis. Power, vol. 53, no. 12, Mar. 22, 1921, pp. 472–473, 1 fig. Study in operating efficiencies and control methods in 48,000 sq. ft. boiler plant using coke oven gas as fuel. Results show CO_2 flue-gas content reliable efficiency indicator, and excess air not requisite for practically complete combustion.

Instruments. A Continuous Densimeter for Boilers. Engr., vol. 131, no. 3398, Feb. 11, 1921, pp. 157–158. Patented apparatus for ascertaining density of boiler water. Principle of operation is that column of distilled water is balanced against column of water contained in boiler.

BOILERS

Baffling. Recent Practice in Baffling Boilers, Kingsley L. Martin. Power Plant Eng., vol. 25, no. 6, Mar. 15, 1921, pp. 135–137, 4 figs. Typical installations of baffles.

Capacity Limitations. Ultimate Boiler Capacity Limited by Stoker Conditions, Joseph Harrington. Elec. Rev. (Chicago), vol. 78, no. 12, Mar. 19, 1921, pp. 451–453, 2 figs. Size and distribution of air openings through grates. Forced draft required to overcome resistance in fuel bed. Formation of clinker influenced by character of coal and other factors.

Feed Regulator. "Anthony" Patent Feed Regulator. Steamship, vol. 32, no. 380, Feb. 1921, pp. 196–198, 2 figs. Patented regulator in which no additional valve for regulating feed water admission need be used, as the special valve provided with apparatus is in itself an automatic check valve, and can be fitted with an isolating valve.

BOILERS, WATER-TUBE

Marine. Water-Tube Marine Boiler (Chaudière marine à tubes d'eau). Bulletin technique du Bureau Veritas, vol. 3, no. 2, Feb. 1921, pp. 55–56, 2 figs. Patented boiler with lateral superheater composed of tubes running in longitudinal direction of boiler. Built by Schmidt'sche Heissdampf Gesellschaft.

BRASS

Cobalt. Cobalt Brasses, Leon Guillet. Chem. & Metallurgical Eng., vol. 24, no. 10, Mar. 9, 1921, pp. 439–443, 11 figs. Experimental comparison of role of cobalt with that of nickel in manufacture of copper-zinc alloys.

Season Cracking. The Season-Cracking of Brass and Other Copper Alloys, H. Moore, S. Beckinsale and Clarice E. Mallinson. Advance Paper, no. 5, meeting of Inst. Metals, Mar. 10, 1921, 91 pp., 23 figs. Experimental investigation of causes of season-cracking at Research Dept., Woolwich, England.

BROACHING MACHINES

Vickers. A New Broaching Machine. Eng. Production, vol. 2, no. 23, Mar. 10, 1921, p. 3289, 2 figs. Machines manufactured by Vickers Works, London, England.

BUILDING CONSTRUCTION

Metal Lath Application. The Correct Application of Metal Lath to Avoid Plaster Cracks. Am. Architect, vol. 119, no. 2358, Mar. 2, 1921, pp. 246–250, 12 figs. Results of tests recently conducted at Armour Institute, showing best forms of application.

C

CABLES, HOISTING

Metallic, Resonance in. Resonance in Metallic Hoisting Cables (La résonance dans les cables d'extraction métalliques), R.-A. Henry. Revue universelle des Mines, vol. 8, no. 3, Feb. 1, 1921, pp. 173–186, 4 figs. Graph is constructed for determining loading and speed which will prevent resonance vibrations in cables of various dimensions.

CAMS

Design. Harmonic Cams With Flat Followers, R. J. Cousins. Automobile Engr., vol. 11, no. 147, Feb. 1921, p. 42, 3 figs. Principles involved in design of cam acting directly on flat-ended tappet.

CAR CONSTRUCTION

Support on Truck. New Type of Support for Railway Cars (Nouveau type de suspension pour voiture à bogies). Génie Civil, vol. 78, no. 8, Feb. 19, 1921, pp. 178–179, 1 fig. Pendulum support. From Revue générale des Chemins de fer.

CAR COUPLERS

Failure. Causes of the Rupture of Railway Car Couplings (Les causes des ruptures d'attelages de chemins de fer). Génie Civil, vol. 78, no. 10, Mar. 5, 1921, pp. 212–215, 14 figs. Interpretation of photomicrographs of ruptured specimens. Failure is attributed to carelessness in forging and insufficiency of elastic resistance in traction springs.

CAR WHEELS

Chilled Cast-Iron. Instruction for Grinding Chilled Cast Iron Car Wheels. Ry. Mech. Engr., vol. 95, no. 3, Mar. 1921, pp. 181–183. Practice of Atchison, Topeka and Santa Fe Railroad. Tables giving grinding diameters for slid flat wheels.

CARS

Automatic Connector. The Futrell Automatic Train Line Connector. Ry. Age., vol. 70, no. 9, Mar. 4, 1921, pp. 516–518, 6 figs. Features are arrangements for locking heads and taking care of movement between couple cars.

Container. Container Car in Express Service on, N. Y. C. Lines. Ry. Mech. Engr., vol. 95, no. 3, Mar. 1921, pp. 171–172, 4 figs. Experimental container car operated by Am. Ry. Express between New York and Chicago. Car consists of nine separate containers or steel boxes firmly secured on car to prevent shifting during train movement. Each container is removable so that it may be transported by motor truck between stores or factories and railroad.

Diesel-Electric. The Diesel Engine in Railroad Service. Ry. Mech. Engr., vol. 95, no. 3, Mar. 1921, pp. 156–159. Diesel-electric cars on Swedish railways.

CARS, FREIGHT

Cost of Reproduction. The Cost of Reproduction of New Steel Freight Cars. Ry. Age., vol. 70, no. 10, Mar. 11, 1921, pp. 553–556, 4 figs. Report issued by Equipment Committee of Presidents' Conference Committee on Federal Valuation. Gondola, hopper, coke and tank cars are taken up. Price is based on weight of so-called base car to which price are added certain net figures to cover cost of specialties.

Six-Wheel Truck. The Lamont Six-Wheel Truck for Freight Cars. Ry. Age, vol. 70, no. 11, Mar. 18, 1921, pp. 729–731, 4 figs. Side frames are continuous over three journals. Special design of equalizing system used.

CASE-HARDENING

Cyanide Action. True Action of Cyanide in Case Hardening Steel, G. R. Brophy and S. B. Leiter. Trans. Am. Soc. for Steel Treating, vol. 1, no. 6, Mar. 1921, pp. 330–338, 13 figs. Interpretation of photomicrographs.

Cyanogen Case Carburizing. A New Method of Case-Hardening Steel, W. J. Merten. Can. Machy., vol. 25, no. 9, Mar. 3, 1921, pp. 77–80, 1 fig. Steel and iron alloy articles are case-hardened in stream of cyanogen gas evolved from container filled with an alkali cyanide salt, heated by electrical energy or other means to accomplish vaporization of salt.

Ingots During Casting. The Composite Process of Carburisation of Steel During Casting, Major Waddington. Iron & Coal Trades Rev., vol. 102, no. 2766, Mar. 4, 1921, p. 311, 3 figs. Ingot mold was lined on one side only with amorphous carbon blocks. Rail was subsequently rolled from ingot, running surface of rail corresponding to side with greater carbon content.

Tests. A Research in Case Carbonizing, G. S. McFarland. Trans. Am. Soc. for Steel Treating, vol. 1, no. 6, Mar. 1921, pp. 297–305, 24 figs. Comparison of 5 per cent nickel steel, carbon steel and chrome-vanadium steel when used for case carbonizing. Nickel steel proved superior to other two.

CAST IRON

Tests. Mechanical Tests for Cast Iron—Part 1, F. G. Cook. Foundry Trade Jl., vol. 23, no. 234, Feb. 10, 1921, pp. 132–134. Survey of tests usually required by engineers' specifications and of those adopted as guide to efficient working in foundry. (To be continued.) Paper read before London Branch, Instn. British Foundrymen.

CEMENT

Slag. Slag Cement (Béton de scories), B. Jeanneret. Bulletin technique de la suisse romande, vol. 47, no. 3, Feb. 5, 1921, pp. 27–29, 2 figs. Tests of strength of blast-furnace slag cement.

CENTRAL STATIONS

Economical Advantages. Progress of the Superpower Survey. Elec. World, vol. 77, no. 10, Mar. 5, 1921, pp. 539–540. Annual saving to railroads of $90,000,000 through electrification and of 4,000,000 tons of coal by the utilities, together with legislative and financial program, stated in superpower survey being made under auspices of United States Dept. of the Interior.

Progress Report of Superpower Survey. Power, vol. 53, no. 10, Mar. 8, 1921, pp. 395–396. Preliminary report covering investigations of superpower survey being made under auspices of United States Dept. of Interior.

Progress Report on the Superpower Survey. Ry. Age, vol. 70, no. 11, Mar. 18, 1921, pp. 727–728. Cost of electrifying railroads within Boston-Washington industrial region estimated at $40,000 per mile. Progress report on work of superpower survey submitted to president by Secretary of Interior.

Superpower and Its Relation to Industry, Henry Flood, Jr. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 3, Mar. 1921, pp. 192–197, 3 figs. Intense industrial development results from central station practice in large demand for power to operate industries and to provide transportation both for raw material into region and for finished products to people outside of it.

Super-Power Stations for Central Indiana, Frederick L. Ray. Power Plant Eng., vol. 25, no. 5, Mar. 1, 1921, pp. 262–264, 1 fig. General outline of needs, advantages and possibilities of system of generating stations, located in coal mining districts, supplying power to entire central part of state.

Steam Hydraulic Relay Service. Steam Stations for Hydraulic Relay Service, E. B. Powell. Power Plant Eng., vol. 25, no. 6, Mar. 15, 1921, pp. 310–315, 6 figs. Consideration of design factors of various types of supplementary power schemes available. Paper presented at joint meeting of Boston Sections of Am. Soc. Mech. Engrs., Am. Inst. Elec. Engrs., and Boston Soc. Civil Engrs.

Superpower. Industries and Superpower, Harold Goodwin, Jr. Jl. Engrs. Club of Phila., vol 38, no. 194, Feb. 1921, pp. 63–68, 5 figs. Survey of power consumption in northeastern part of U. S., including greater part of New England and New York, New Jersey and Delaware, and part of Pennsylvania and Virginia. Figures of 1914 census indicate that there are about 10,000,000 hp. in zone, and that coal consumption amounts to 60,000,000 tons per annum. Advantages of centralizing power generation are pointed out.

CLOTHS

Mechanical Uses. Cloths for Mechanical Uses, James W. Cox, Jr. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 177–180 and 220. Classification of cloths, enumeration of industries in which they are used, and exposition of their specific uses as absorptives, and for belting, conveying, filtering, etc.

COAL

Briquetting. Briquetted Coal for Household Fuel, J. H. Kennedy. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 2, Mar. 1921, pp. 101–106. European practice.

Cannel. Cannel Coal in Southern Utah, C. A. Allen. Reports of Investigations, Bureau of Mines, Dept. of Interior, Feb. 1921, serial no. 2221, 3 pp. Possibilities of commercial utilization. Over 68 gal. of oil were recovered per ton of coal in experiments.

Recovery from Furnace Refuse. Recovery of Coal from Furnace Refuse. (Kohlengewinnung aus den Feuerungsruckständen). Zeit. für die gesamte Giessereipraxis, vol. 42, no. 3, Jan. 15, 1921, pp. 36–38, 1 fig. "Kolumbus" coke separator based on principle of separation of coke and slag through specific weight.

COAL DEPOSITS

Pennsylvania. Pennsylvania Coals and Shales Greatly Vary in Their Content of Oil, Geo. H. Ashley and Chas. R. Fettke. Coal Age, vol. 19, no. 9, Mar. 3, 1921, pp. 401–403. Comparison of coal deposits and oil resources of Pennsylvania with those of other states.

COAL DUST

Precautions against. Precautions Against Coal Dust. Iron & Coal Trades Rev., vol. 102, no. 2765, Feb. 25, 1921, p. 283. Orders issued by British Secretary of Mines regarding tests to be adopted in connection with precautions against coal dust.

COAL HANDLING

Brown Electric Shovel. By Making Boom Horizontal, Surface Type of Shovel is Adapted to Mine Work, D. C. Ashmead. Coal Age, vol. 19, no. 9, Mar. 3, 1921, pp. 395–396, 2 figs. Brown electric shovel provided with horizontal boom, automatic dipper trip and conveyor.

COAL WASHING

Froth Flotation. Purification of Coal by Froth Flotation. Colliery Guardian, vol. 121, no. 3136, Feb. 4, 1921, pp. 337. Process for recuperating coal dust from refractory fines.

COKE OVENS

Linings. Silica Bricks for Coke Ovens. Iron & Coal Trades Rev., vol. 111, no. 2764, Feb. 18, 1921, pp. 232–233. Comparison of silica and firebrick linings.

COMBUSTION

Control. Control of Combustion (La comburimétrie industrielle), A. Grebel. Génie Civil, vol.

78, nos. 4 and 5, Jan. 22 and 29, 1921, pp. 78–82, 4 figs., and 103–104, 3 figs., Jan. 22. Grebel-Velter apparatus for controlling combustion. Jan. 29: The Frère air recorder.

Stephens Process. Grateless, Smokeless, Automatic Furnace for Steam Power Production at the Mines. Blast Furnace & Steel Plant, vol. 9, no. 3, Mar. 1921, p. 229, 1 fig. Downward sweep of air coming through front of furnace carries measured quantities of fuel consisting of dust and fine particles up to pieces 3/4 in. in size. Dust and fine particles burn in suspension. While burning particles are agitated in vortex maintained within furnace chamber.

CONCRETE

Proportioning Aggregates. New Methods of Proportioning Concrete. Can. Engr., vol. 40, no. 9, Mar. 3, 1921, pp. 263–265. Specifications adopted by Hydroelectric Power Commission of Ontario.

Use in Sea Water. Report of Committee VIII—On Masonry. Bul. Am. Ry. Eng. Assn., vol. 22, no. 233, Jan. 1921, pp. 543–564, 11 figs. Disintegration of concrete and corrosion of reinforcing materials in connection with use of concrete in sea water. Effect upon strength and durability of concrete not having sufficiency of moisture present throughout period of hardening.

Waterproof. How Concrete is Made Waterproof, James Scott. Contract Rec., vol. 35, no. 8, Feb. 23, 1921, pp. 198–199, 4 figs. Analysis of microscopical actions and chemical modifications taking place on addition of "pudlo" to concrete.

Wear Under Water. Water Content Affects Wear of Concrete Test Pieces, Dan Patch. Eng. News-Rec., vol. 86, no. 9, Mar. 3, 1921, pp. 373, 1 fig. Report of behavior of test pieces placed in Boston harbor in 1909.

CONCRETE CONSTRUCTION, REINFORCED

Calculation. Short Cuts for Calculating and Estimating Reinforced Concrete, Milo S. Farwell. Am. Architect, vol. 119, no. 2358, Mar. 2, 1921, pp. 251–254, 14 figs. Graphs for computing costs.

CONDENSERS, STEAM

Cooling of Water in Canal. The Cooling of Water in a Canal, L. C. Kemp. English Elec. Jl., vol. 1, no. 5, Jan. 1921, pp. 210–222, 8 figs. Experiments carried out at Lero Road Power Station, Leicester, England. Situated on banks of canal upon which it relies entirely for cooling of circulating water for condensers.

Incrustation. The Scam-Balcke Process for Preventing Incrustation in Surface Condensers (La "vaccination" des eaux de circulation des condenseurs à surface par le procédé Scam-Balcke). Génie Civil, vol. 78, no. 7, Feb. 12, 1921, pp. 153–157, 12 figs. Addition of hydrochloric acid to transform carbonates into chlorides is basis of process.

Tests. Test Results of a 50,000 Square-Foot Surface Condenser. Power, vol. 53, no. 11, Mar. 15, 1921, pp. 414–416, 4 figs.

COPPER ALLOYS

Copper-Tin. The Constitution of the Alloys of Copper with Tin. Parts III and IV, John L. Haughton. Advance Paper no. 6, meeting of Inst. Metals, Mar. 10, 1921, 22 pp., 23 figs. Experimental study of transformations other than formation of eutectic occurring below 250 deg. cent.

Plastic Deformation. Plastic Deformation of Some Copper Alloys at Elevated Temperatures, C. A. Edwards and A. M. Herbert. Advance Paper, no. 3, meeting of Inst. Metals, Mar. 9, 1921, 25 pp., 11 figs. Experimental investigation.

CORROSION

Browning Rust-Prevention Process. Rust Prevention by Browning Process, W. C. Marshall. Automotive Industries, vol. 44, no. 10, Mar. 10, 1921, pp. 556–558. Specifications for preparation of solutions and methods of application.

Steel Containing Copper. Corrosion Tests with Steel Plates Containing Copper (Rostversuche mit kupferhaltigen Eisenblechen), O. Bauer. Stahl u. Eisen, vol. 41, nos. 2 and 3, Jan. 13 and 20, 1921, pp. 37–45 and 76–83, 11 figs. Account of tests carried out in a pure atmosphere (on roof of material-testing station in Berlin-Dahlem), at the seashore (North Sea), and in industrial district in Westphalia. It is shown that a small addition of copper to iron is a good protection against unfavorable effect of sulphuric acid; phosphorus greatly increases the susceptibility of iron to sulphuric acid and addition of copper neutralizes to certain extent the unfavorable action of phosphorus.

COST ACCOUNTING

Indirect Costs. Aligning the Power Plant with the Cost Department, Malcolm C. W. Tomlinson. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 171–172. Suggestions in regard to reducing power, light and heat costs.

Relation to Production. Costing Methods and Increased Productivity, H. W. Allingham. Eng. & Indus. Management, vol. 5, no. 7, Feb. 17, 1921, pp. 196–198. Discussion held under auspices of British Instn. of Cost and Works Accountants.

CRANE HOOKS

Stresses in. The Strength of a Hook or "Clivvy," Charles D. Mottram. Colliery Guardian, vol. 121, no. 3137, Feb. 11, 1921, pp. 411–412, 4 figs. Measurement of stresses in crane hook where maximum load was 5 tons.

CRANES

Shipyards. Shipyard Cranes, H. H. Vernon. Gen. Elec. Rev., vol. 24, no. 3, Mar. 1921, pp. 230–233, 11 figs. Typical installations of electrically-operated cranes at American shipyards.

CRANKSHAFTS

Manufacture. Crankshaft Turning Practice, J. V. Hunter. Am. Mach., vol. 54, no. 11, Mar. 17, 1921, pp. 456–458, 7 figs. Cheeks, pins and bearings turned in special lathes. Shafts driven from both ends by pot-chucks. Special tooling methods employed.

Quantity Making of Crankshafts. Abrasive Industry, vol. 2, no. 2, Feb. 1921, pp. 49–52, 6 figs. Methods at plant of Automobile Crank Shaft Corp., Detroit.

CYLINDERS

Boring. Methods in a Tractor Engine Plant. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 641–644, 8 figs. Method of machining cylinder liners on rotary type of boring machine at plant of Avery Co., Milwaukee.

D

DIES

Curling. Curling Die Construction, J. Bingham. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 651–652, 4 figs. Punch and die designed to flange out bottom of drinking cup shell and to curl top.

Drop-Forging. Life of Drop Forge Dies, J. S. Glover. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 120–123, 1 fig. Suggests general systematic handling scheme.

Electrical Fixtures. Dies for Electrical Terminals and Connectors, John A. Honegger. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 626–629, 10 figs. Dies employed in manufacture of connectors or terminals for wires of electric lighting units.

Manufacture. Dies for Hemispherical, Conical and Other Flanged Shells, J. Bingham. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 546–548, 8 figs. Details of manufacture and methods of operation.

Piercing. The Design and Construction of Press Tools—II. Eng. Production, vol. 2, no. 20, Feb. 17, 1921, pp. 212–214, 7 figs. Types of piercing dies.

DIESEL ENGINES

Burmeister-Wain. First Details of New Burmeister and Wain Engine for Single Screw Motorships. Motorship, vol. 6, no. 3, March 1921, p. 216, 2 figs. Long-stroke Diesel engines with piston removable from below.

Canadian-Built. The First True Diesel Made in Canada. Power House, vol. 14, no. 5, Mar. 5, 1921, pp. 21–24, 8 figs. Also Can. Machy., vol. 25, no. 11, Mar. 17, 1921, pp. 41–44, 8 figs. Description of 100-b.hp. four-cylinder Diesel engine built by Dominion Steel Products Co.

Double-Acting. The Double-Acting Diesel Engine, A.P. Chalkley. Pacific Mar. Rev., vol. 18, no. 3, Mar. 1921, pp. 149–150, 4 figs. Installation in motorship "Assyrian."

Installations in United States. The Diesel-Engine Industry, L. H. Morrison. Power, vol. 53, no. 9, Mar. 1, 1921, pp. 336–340, 6 figs. Table giving Diesel-engine installations in U. S. by industries, also statistics on installations by states.

Marine. Cooling of Cylinders and Pistons of Marine Diesel Engines, Louis R. Ford. Power, vol. 53, no. 11, Mar. 15, 1921, pp. 426–429, 3 figs. Study of causes of typical piston failures.

Diesel Engine Crankshafts, Joseph Hecking. Mar. Eng., vol. 26, no. 2, Feb. 1921, pp. 147–153, 9 figs. Investigation made in connection with classification rules of Am. Bur. of Shipping.

Standardization. Standardized Diesel Engines, H. R. Setz. Mar. Eng., vol. 26, no. 3, Mar. 1921, pp. 222–228, 6 figs. Suggestions in regard to standardization of four-cycle type. (To be continued.)

DRAWING

Machine Parts. The Relative Economic Value of Drawn Machine Parts and Those Machined from Solid Materials (Wirtschaftlicher Vergleich zwischen gezogenen und aus Vollmaterial hergestellten Maschinenteilen), K. Brendle. Betrieb, vol. 3, no. 8, Jan. 25, 1921, pp. 207–210, 8 figs. A typical example, with preliminary calculations and comparative tables, are given to show that parts machined from solid material could often be produced at much lower cost through drawing.

DRILL CHUCKS

Interchangeable Manufacture. Application of Interchangeability to Drill Chuck Manufacture, Fred. R. Daniels. Machy. (N. Y.), vol. 27, nos. 6 and 7, Feb. and Mar. 1921, pp. 509–515, 9 figs., and 674–679, 18 figs. Tooling and gaging equipment used by Marvin & Casler Co., Canastota, N. Y., in manufacturing Casler twin-screw drill chuck.

DRILLING MACHINES

Multiple. A Machine for Multiple Drilling and Tapping. Automotive Industries, vol. 44, no. 11, Mar. 17, 1921, pp. 611. Employs automobile type friction clutch in main driving pulley to enable power to be shut off when change in direction of rotation of spindles is made.

DRILLS

Pneumatic. Four-Cylinder Pneumatic Drill. Engineering, vol. 111, no. 2879, Mar. 4, 1921, p. 253, 4 figs. Light design with aluminum castings.

DUST

Determination in Air. Efficiency of the Sugar-Tube Method for Determining Dust in Air, A. C. Fieldner, S. H. Katz and E. S. Longfellow. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 2, Mar. 1921, pp. 119–123, 2 figs. Experiments at U. S. Bur. of Mines.

Removal from Grinding Plants. Investigation of Dust in the Air of Granite-Working Plants, S. H. Katz. Reports of Investigations, Bur. of Mines, Dept. of Interior, Feb. 1921, serial no. 2213, 2 pp. Methods used by U. S. Bureau of Mines in coöperation with Granite Manufacturers' Assn. for determining dustiness in granite-working plants.

Reducing Grinding Hazards. Abrasive Industry, vol. 2, no. 2, Feb. 1921, pp. 37–41, 9 figs. Tests conducted in various manufacturing plants by the U. S. Public Health Service revealed that grinders' consumption is prevalent to a great extent in wet grinding plants. Methods of disposing of dust are surveyed.

DYNAMOMETERS

Proude Hydraulic. The Froude Hydraulic Dynamometer, C. H. Peabody. Mar. Eng., vol. 26, no. 3, Mar. 1921, pp. 244–247, 4 figs. Reversible and non-reversible types built in standard sizes up to 6000 hp. by C. H. Wheeler Manufacturing Co.

E

EDUCATION, ENGINEERING

Industries and. What Our Engineering Colleges Owe Our Industries, Robertson Matthews. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 155–158. More character-building, even at expense of specialized training, urged to supply industry with leaders who have human touch.

ELECTRIC CONDUCTORS

See ALUMINUM, Electric Conductors.

ELECTRIC DRIVE

Machine Tools. Standardizing Motors for Tools, H. R. Weedon. Iron Trade Rev., vol. 68, no. 8, Feb. 24, 1921, pp. 555–557, 3 figs. Urges coöperation between motor manufacturers and machine-tool makers in securing possible application of general types of electric motors to machine tools. Paper read before Nat. Machine Tool Builders' Assn.

Mounting Motors. Mounting Motors to Afford Convenience, J. S. Thomas. Elec. World, vol. 77, no. 11, Mar. 12, 1921, pp. 594–597, 3 figs. Methods of mounting motors to increase free space in shop. Typical installations.

Paper Machines. Automatic Speed Control for Sectional Paper Machine Drive, Stephen A. Staege. Elec. Jl., vol. 18, no. 3, Mar. 1921, pp. 78–82, 5 figs. Schematic plan and wiring diagram of Westinghouse system of sectional individual motor drive.

Rubber Industry. The Application of Electric Power to the Rubber Industry. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 1, Jan. 1921, pp. 35–47. Possibilities of electric power. Application of 40-degree and 50-degree motors. Steam versus electrically heated drying ovens. Steam versus electric heat treatment of vegetable compounds.

Textile Mills. Continental Practice in the Electrical Driving of Textile Factories, W. Dundas Fox. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 165–168, 6 figs. Experiments with electric drive at works of Max Schorch & Co., Germany.

Modern Methods of Driving Machines in Jute Manufacture, T. Woodhouse and P. Kilgour. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 159–165, 9 figs. Advantages of electric drive.

Some Considerations in the Application of Electricity to Textile Mills, J. T. Randles. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 153–156, 6 figs. Estimates of power requirements.

The Individual Electric Drive, Frank Nasmith. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 157–159, 6 figs. Developments in application of electric drive in textile mills in U. S.

The Individual Gear Drive for Heavy Looms, G. F. Sills. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 150–153, 8 figs. Typical installations.

The Use of Gears and High Speed Motors in Textile Mills, George S. Sharman. Elecn., vol. 84, no. 2229, Feb. 4, 1921, pp. 168–171, 6 figs. Practice in English mills.

Tinplate Mills. Electricity in the Tinplate Industry, L. Rothera. English Elec. Jl., vol. 1, no. 5, Jan. 1921, pp. 190–198, 10 figs. Typical installations and records of their operation.

ELECTRIC FURNACES

Héroult. First Heat From Naval Electric Furnace. Iron Age, vol. 107, no. 10, Mar. 10, 1921, pp. 617–619, 2 figs. Forty-ton Héroult furnaces operated by U. S. Naval Ordnance plant at So. Charleston, West Va., for refining and finishing steel for gun forgings, armor plate, armor piercing projectiles, and other high-grade miscellaneous forgings.

Iron Founding. Cost of Synthetic Gray Iron Low, R. C. Gosrow. Foundry, vol. 49, no. 6, Mar. 15, 1921, pp. 242–243. Tables giving cost of electrically melted gray iron produced from iron and from steel.

Electric Furnace Improves Gray Iron, Richard Moldenke. Foundry, vol. 49, no. 6, Mar 15, 1921, pp. 216–218. Sulphur lowered by treating cupola metal or melting direct on basic bottom. Paper read before Am. Inst. Min. & Metallurgical Engrs.

The Electric Furnace in the Iron Foundry, Richard Moldenke. Min. & Metallurgy, no. 170, Feb. 1921, p. 32. Advantages of basic-hearth electric furnace. (Abstract.)

Steel Manufacture. Electric Furnace for High-Speed Steel. Iron Age., vol. 107, no. 11, Mar. 17, 1921, pp. 691–692. Newkirk furnace of two tons capacity, with graphite electrodes and specially constructed bottom electrode.

ELECTRIC LOCOMOTIVES

German. Cars for the Electric Operation of the Berlin Railways (Die Fahrzeuge für den elektrischen Betrieb der Berliner Bahnen), H. Wechmann. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 7, Feb. 12, 1921, pp. 170–174, 14 figs. The locomotive of the German General Electric Co. (AEG) is driven by a series commutator motor of 450 to 460 kw. capacity at speeds of 36 to 60 km. per hr.; weight on driving axle, 17 tons. Notes on recent trial operation of short-train with passenger locomotive of the Siemens-Schuckert Works (SSW); each short has two locomotives each equipped with two motors of 260 kw. capacity.

ELECTRIC RAILWAYS

Operation. The Use of Helpers in Electric Train Operation, W. F. H. Hamilton. Ry. Age, vol. 70, no. 8, Feb. 25, 1921, pp. 455–458, 2 figs. Speed-tractive effort curves on resistance for electric freight locomotives used on Chicago, Milwaukee & St. Paul.

ELECTRIC WELDING

Machines. Electric Welding. Automobile Engr., vol. 11, no. 148, Mar. 1921, pp. 105–109, 18 figs. Methods and machines employed. Tests of welds.

ELECTRIC WELDING, ARC

Foundry Equipment. Arc Welding Equipment in the Foundry, W. W. Reddie. Elec. Jl., vol. 18, no. 3, Mar. 1921, pp. 96–99, 10 figs. Equipment for cutting heavy risers and sink heads from steel or iron castings or for filling blow holes of castings.

Metal Deposition. Phenomena of Arc Welding, O. H. Eschholz. Thirty-ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 8, pp. 59–71, 16 figs. Discussion of metal deposition, fusion and arc stability during electric welding.

Studding. Studding for Arc Welding, C. J. Holslag. Welding Engr., vol. 6, no. 2, Feb. 1921, pp. 25–28, 6 figs. Studding is used where weld is in such position that parts are not free to align themselves to contracting strains which result during cooling. Paper read before Metropolitan Section, Am. Welding Soc.

Tests. Solving Some Arc Welding Problems, A. M. Candy. Foundry, vol. 49, no. 5, Mar. 1, 1921, pp. 179–185, 19 figs. Experiments on strength of welds, current values under varied conditions and rates of cutting different materials. Paper read before Am. Foundrymen's Assn.

EMPLOYMENT MANAGEMENT

Interviewing Applicants. Interviewing for Selection, Earl B. Morgan. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 159–164. Qualifications required for interviewing successfully.

Selection of Employees. Hiring and Placing Men. Iron Age, vol. 107, no. 11, Mar. 17, 1921, pp. 705–706. Methods followed at works of Am. Rolling Mill Co.

ENGINEERS

Registration. The Licensing of Engineers. Min. & Sci. Press, vol. 122, no. 9, Feb. 26, 1921, pp. 297–298. Bill has been introduced in Montana Legislature proposing to create State Board of Engineering Examiners for purpose of licensing engineers. Article gives report on bill prepared by committee of Montana Section, Am Inst. Min. & Metallurgical Engrs. Committee are adverse against passing of bill on ground that it is not necessary and that it will impose burden in time and money on engineers.

Remuneration. Incomes in Engineering Profession Compared with Others. Eng. News-Rec., vol. 86, no. 9, Mar. 3, 1921, p. 387, 2 figs. Iowa Engineering Society investigation of net income of doctors, lawyers and dentists indicates engineers low.

EVAPORATORS

Power Test Code. Test Code for Evaporating Apparatus. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 184–187. Preliminary draft of third of series of nineteen codes in preparation by Am. Soc. Mech. Engrs. Committee on power test codes. Code is intended primarily for apparatus heated by steam such as vacuum pans, or single and multiple-effect evaporators.

EXECUTIVES

Qualifications. Getting Executive Leadership, W. R. Basset. Am. Mach., vol. 54, no. 12, Mar. 24, 1921, pp. 492–496. Danger of over-organization. One-man versus committee form of control. Advantages of competitive decentralization.

EXHAUST STEAM

Utilization of. Power from Exhaust Steam. Power Plant Eng., vol. 25, no. 6, Mar. 15, 1921, pp. 303–307, 10 figs. Installation of turbo-generators driven by exhaust steam at plant of Western Drop Forge Co., Marion, Ind.

F

FACTORIES

Layout. Plant of The James Leffel & Co. Power Plant Eng., vol. 25, no. 5, Mar. 1, 1921, pp. 253–257, 10 figs. Layout of plant manufacturing water turbines generates steam for power, light and heat.

Reinforced-Concrete. Extension to Dunlop Tire Co.'s Plant, Toronto. Can. Engr., vol. 40, no. 9, Mar. 3, 1921, pp. 259–263, 9 figs. Flat-slab reinforced concrete construction. Four-way system and hooped interior columns.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FANS, CENTRIFUGAL

Performance. Centrifugal Fans or Blowers, Their Performance and Functions, Fred R. Still. Jl. Engrs. Club of Phila., vol. 38, no. 194, Feb. 1921, pp. 72–76. Notes on design, performance and application.

Steel Works. Fatigue and Efficiency in an Iron and Steel Works, H. M. Vernon. Eng. and Indus. Management, vol. 5, no. 7, Feb. 17, 1921, pp. 201–208, 5 figs. Data compiled by British Ind. Fatigue Research Board.

FERROALLOYS

Iron-Nickel. Iron- Nickel Alloys, Paul D. Merica. Chem. & Metallurgical Eng., vol. 24, no. 9, Mar. 2, 1921, pp. 375–378, 7 figs. Properties and behavior of iron-nickel alloys.

[See also FERROMANGANESE; FERROSILICON.]

FERROMANGANESE

Manufacture in Electric Furnace. Manufacture of Ferromanganese in the Electric Furnace, Robert M. Keeney and Jay Lonergan. Min. & Metallurgy, no. 170, Feb. 1921, pp. 30–31, 2 figs. Electric-furnace production of ferromanganese in 1920 amounted to 10,000 tons. There are now installed 33 electric furnaces of from 350 kva. to 5000 kva. capacity with total installed transformer capacity of 58,000. (Abstract.)

FERROSILICON

Properties. Influence of Silicon Upon the Properties of Ferrosilicon, A. T. Lowzow, Chem. & Metallurgical Eng., vol. 24, no. 11, Mar. 16, 1921, pp. 481–484, 9 figs. Investigation of samples of ferrosilicon containing from 49.1 per cent to 77.46 per cent silicon. Physical and chemical properties were determined. Translated from Tidskrift for Kemi.

FITS

Forced. Chart of Pressures for Forced Fits. Machy. (London), vol. 17, no. 439, Feb. 24, 1921, p. 648, 1 fig. Chart for determining pressure required to assemble parts having forced fit. Computed from standard formulas.

FLAME PROPAGATION

Closed Cylinder. The Nature of Flame Movement in a Closed Cylinder, C. A. Woodbury, H. A. Lewis and A. T. Canby. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar. 1921, pp. 209–218, 21 figs. Experimental work undertaken to determine characteristic flame movement of automobile fuels and physical and chemical properties which influence it. Theory is developed that arrests occurring in mixture fired without turbulence and consequent vibrations observed in burning gases are due to high density developed in gases ahead of flame front. Knock is explained by auto-ignition of high density gases ahead of flame front.

FORGING

Hydraulic-Press Operations. Hydraulic Forge Press Operations. Am. Mach., vol. 54, no. 11, Mar. 17, 1921, pp. 467–469, 3 figs. Data on work required for punching operation. Examples of forging various types of shells and tubes.

FOUNDING

Research. The Value of Scientific Research to Iron Founding, J. G. Pearce. Foundry Trade Jl., vol. 23, no. 234, Feb. 10, 1921, pp. 123–124. Experience of British Cast Iron Research Assn.

FOUNDRIES

Electrically Operated. Foundry is Electrically Operated, H. E. Diller. Iron Trade Rev., vol. 68, no. 8, Feb. 24, 1921, pp. 559–563, 8 figs. Current is utilized for melting furnace charges, annealing castings and for baking molds and cores. Annealing operation is intermittent. How light steel castings are made.

Layout. Types of Foundry Buildings. Foundry Trade Jl., vol. 23, no. 236, Feb. 24, 1921, pp. 170–171, 1 fig. Suggested layout for foundries.

Waste Reclamation. The Reclamation of Metals from Foundry Waste, J. P. Norrie. Can. Chem. & Metallurgy, vol. 5, no. 3, Mar. 1921, pp. 77–79, 3 figs. Reclaiming and smelting process of Rome Brass & Copper Co., Rome, N. Y.

FUELS

Industrial Uses. Form Value of Energy in Relation to Its Production, Transportation and Application, Chester G. Gilbert and Jos. E. Pogue. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 139–144, 2 figs. Factors covering selection of fuel for industrial heating. Comparative cost per B.t.u. at unit prices for bituminous and anthracite coal, natural gas, city gas, oil fuel, kerosene oil, gasoline and electricity.

Liquid and Gaseous from Coal. Coal as a Future Source of Oil Fuel Supply, Arthur Duckham. Jl. Instn. Petroleum Technologists, vol. 7, no. 25, Jan. 1921, pp. 3–12 and (discussion), pp. 13–26. Scheme for manufacture of liquid and gaseous fuels from coal is suggested which involves total gasification of coal in one vessel, and condensation and recovery of volatiles in liquid form, distillation being carried out at such temperatures and in such manner that minimum of cracking takes place.

Thermalene. New Fuel. Power House, vol. 14, no. 4, Feb. 20, 1921, p. 29. Mixture of acetylene and vaporized oil named thermalene, consisting of alternate layers of calcium carbide and crude oil absorbed in sawdust.

[See also AUTOMOBILE FUELS; COAL; LIGNITE; OIL FUEL; PEAT; PULVERIZED COAL; WATER GAS.]

FURNACES, BOILER

Rotating-Hearth. A New Type of Mechanical Furnace—The Rotating Hearth Romanet Furnace (Un nouveau type de foyer méchanique: la grille à sole tournante), A. Colomb. Chaleur et Industrie, vol. 2, no. 1, Jan. 1921, pp. 27–34, 7 figs. Fire grate is circular and rotates continuously in horizontal plane.

FURNACES, FORGING

Gas-Fired. The Application of Gas Fuel to Forging. Iron Age, vol. 107, no. 11, Mar. 17, 1921, pp. 703 and 745–746. Requirements for satisfactory forging-furnace fuel. Comparison of gas with oil and coal.

Siemens. Small Forge Furnace of Regenerative Type, F. J. Denk. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 107–108 and 111, 4 figs. European progress in design of Siemen's regenerative type of forging furnace.

FURNACES, HEAT-TREATING

Car vs. Car-and-Ball Type. Car Type and Car-and-Ball Type Furnaces. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 112–119, 9 figs. Factors determining selection of type of heat-treating furnace.

FURNACES, HEATING

Gas-Burning. The Possibilities of Gaseous Heating, W. Newton Booth. Gas Jl., vol. 153, no. 3011, Jan. 26, 1921, pp. 223–227, 4 figs. Data on efficiency of gas-burning furnaces. Paper read before London & Southern District Junior Gas Assn.

Stoker-Fired. Stoker Fired Heating Furnace Installation, Nelson G. Phelps. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 123–126, 7 figs. Data on performance of heavy-duty plate and angle-heating furnaces installed by New York Shipbuilding Corporation.

FURNACES, INDUSTRIAL

Gas-Fired. Gas Furnaces for Melting Non-Ferrous Metals, M. A. Combs. Chem. & Metallurgical Eng., vol. 24, no. 12, Mar. 23, 1921, pp. 515–516, 1 fig. Economical comparison of gas-fired furnaces with electric furnaces and oil-fired furnaces.

G

GAGES

Block. New Precision Measuring Device. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 657–658, 2 figs. Device for measuring within hundred-thousandth part of an inch by use of only six precision measuring blocks, designed by B. M. W. Hanson, Hartford, Conn.

Interference Bands. The Hilger Interference Gauge. Engr., vol. 131, no. 3398, Feb. 11, 1921, p. 157, 3 figs. Shows with certainty differences of 0.00001 in. and permits estimation of differences of 0 000001 in.

GAS

Industrial Uses. Conserving Coal through the Use of Gas, W. A. Ehlers. Coal Age, vol. 19, no. 9, Mar. 3, 1921, pp. 397–400, 3 figs. Elimination of waste through easy regulation and control of heat within narrow limits is cited as advantage of gas over coal for industrial uses.

GAS MANUFACTURE

Dayton Process. The Dayton Process, F. C. Binnall. Jl. Indus. & Eng. Chem., vol. 13, no. 3, Mar. 1921, pp. 242–246, 5 figs. Air-oil gas process in which partial combustion of certain constituents of oil takes place within retort or reaction chamber itself, thus supplying internally all heat necessary for thermal decomposition of hydrocarbons.

Mixing Various Coals. Mixed Coal Experiments, Wm. C. Butterworth. Gas Rec., vol. 19, no. 5, Mar. 9, 1921, pp. 11–13. Tests of mixing various coals for gas making. Scheme has been developed to improve quality of coke and reduce coal costs.

GAS TURBINES

Holzwarth. A New Gas Turbine. Engr., vol. 131, no. 3398, Feb. 11, 1921, pp. 143 and 145. Resumption at works of Thyssen & Co. of experiments with gas turbine invented by H. Holzwarth, described in Engr., Dec. 8, 1911 and Jan. 5, 1912. Tests are being directed to obtaining of more economical pressure of exploding gas, and it is reported that they have been largely successful in so far as effective pressure of 170 lb. to 200 lb. per sq. in. is now obtained, as against 70 lb. to 85 lb. per sq. in. formerly.

GASOLINE

Production in United States. Quality of Gasoline Marketed in the United States, H. H. Hill and E. W. Dean. Dept. of Interior, Bur. of Mines, bul. 191, 1920, 275 pp., 22 figs. Production in U. S. has increased approximately 7,000,000 bbl. for calendar year of 1918. Quantity of crude oil handled in refineries has increased from 67,000,000 bbl. in 1904 to 326,000,000 bbl. in 1918. Yield of gasoline 42-gal. bbl. of crude oil has increased from 413 gal. in 1904 to 11 gal. in 1918.

GEAR CUTTING

Machine for. Machine for Cutting Small Spur or Bevel Gears. Machy. (London), vol. no, 17. 439,

Feb. 24, 1921, pp. 647–648, 3 figs. Knee-type horizontal machine built by T. Ratcliffe, Manchester, England.

Reinecker Turbine Reduction-Gear Hobbing Machines. Am. Mach., vol. 54, no. 10, Mar. 10, 1921, pp. 416–417, 4 figs. Three large German mcahines for hobbing gears up to $19^1/_2$ ft. in diameter. Traversing hob used.

Rapid. Some Examples of Fast Gear Cutting, S. A. Hand. Am. Mach., vol. 54, no. 12, Mar. 24, 1921, pp. 503–504, 4 figs. Practice at shop of Gould & Eberhardt, Newark, N. J.

GEARS

Bevel. Generating Bevel Gears, H. E. Kitchen. Machy. (London), vol. 17, no. 440, Mar. 3, 1921, pp. 669–670, 4 figs. Attachment manufactured by Matterson, Ltd., England, for generating bevel gears on shaping machine.

Inspection. Proposed Methods of Automotive Gear Inspection. Automotive Industries, vol. 44, no. 11, Mar. 17, 1921, pp. 609–610. Gear Makers' Assn. developing standard practice for inspection of their product. Size of hole, wear of gages, tapered holes, keyways, tooth bearing, splined shafts and methods of test are some of items considered.

Involute. The Involute Gear, Francis W. Shaw. Machy. (London), vol. 17, no. 438, Feb. 17, 1921, pp. 617–618, 10 figs. Fisher segmental involute tooth.

The Maag System of Gearing. Machy. (Lond.), vol. 17, no. 437, Feb. 10, 1921, pp. 575–581, 13 figs. System developed by Max Maag, Zurich. Standards for pitches, relations between addenda and dedenda and pressure angle are subsidiary, that is, any pitches are possible.

Spiral. Chart for Selecting Spiral Gears, C. W. Mapes Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 569–570, 1 fig. Chart developed to aid in selecting and calculating spiral gears with shafts at right angles to each other.

GRINDING

Cylindrical. Cylindrical Grinding in 1920, W. H. Chapman. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 173–176, 2 figs. Study of laws involved in cylindrical grinding and analysis of grinding action both for draw-in cuts and traversed cuts. Formulas are derived for wheel wear in terms of known variables such as grain size of wheel, work speed, wheel speed, feed, etc. Production costs are also discussed as well as factors that should be considered in securing highest possible grinding efficiency.

Diamonds. Diamonds for Industrial Purposes, Maurice S. Dessau. Abrasive Industry, vol. 2, no. 1, Jan. 1921, pp. 8–9, 8 figs. Machine and processes for grinding diamonds.

Dust Removal. Reducing Grinding Hazards. Abrasive Industry, vol. 2, nos. 2 and 3, Feb. and Mar., 1921, pp. 37–41, 9 figs., and 101–105, 8 figs. Constant inhalation of abrasive dust causes serious pulmonary affections. Causes of excessive dust and its disposal are explained. Attention to work rests, it is claimed, will eliminate many accidents.

H

HANDLING MATERIALS

Factories. Intra-Factory Transportation, L. R. Clapp. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 195–197. Practice of Ford Motor Co.

Monorail System in German Shell Plant, Hubert Hermanns. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 117–119, 22 figs. Overhead trolley system for transportation of shells.

Putting the Factory Floor on Wheels. Factory vol. 26, no. 4, Feb. 15, 1921, pp. 475–479, 18 figs. System of handling materials installed in plant of Automatic Electric Washer Co.

Railways. Problems of Handling Material and Freight on Railroads, Charles N. Winter. New England Railroad Club, Feb. 8, 1921, pp. 289–323. Equipment used.

HANGARS

Reinforced-Concrete. Reinforced Concrete Hangars for Housing of Two Dirigible Balloons at Lucon, France (Hangar enbéton armé pour deux dirgieables à Lucon (Vendee), Ch. Dantin. Génie Civil, vol. 78, no. 7, Feb. 12, 1921, pp. 145–148, 7 figs. Dimensions: Length, 220 meters; width, 109.6 meters; total height, interior, 53 meters.

Wire-Rope Roof. Use of Wire Rope for the Construction of Work Shops and Aircraft Hangars with Suspension Roof (L'application des cable à la construction d'ateliers et de hangars pour avions ou dirigeables, à toiture suspendue), G. Leinekugel Le Coco, Génie Civil, vol. 78, no. 10, Mar. 5, 1921, pp. 205–211, 20 figs. partly on supp. plate. Typical installations at Cherbourg, France, and at Karouba, Tunis. Considerations of design of such structures.

HEALTH

Industrial. Health Service in Industry. Nat. Indus. Conference Board, report no. 34, Jan. 1921, 61 pp., 2 figs. Survey of developments in organization of medical department in industries, and discussion of method of procedure which have been applied advantageously in individual establishments.

HEATING, ELECTRIC

Advantages. Electric Heating and the Importance of Its Developments in France (Le chauffage électrique et les advantages de son développement en France). Génie Civil, vol. 78, no. 7, Feb. 12, 1921, pp. 148–151, 2 figs. Economic comparison of electric heating with other heating processes. Survey of developments in industrial electric heating in U. S., Canada, Scandinavian countries, Switzerland, etc.

Household Uses. Thermal Characteristics of Electric Ovens and Hot Plates. Engineer, vol. 131, no. 3399, Feb. 18, 1921, pp. 176–177. Tests at National Physical Laboratory, England, on efficiency of hot plates for roasting, baking, frying and boiling.

HEATING, HOT-AIR

Research. Progress Report of Committee on Furnace Heating, A. C. Willard and A. P. Kratz. Jl. Am. Soc. Heat & Vent. Engrs., vol. 27, no. 2, Mar. 1921, pp. 124–132, 4 figs. Proposed furnace-testing codes for both pipeless and piped furnace systems as developed in warm-air furnace research work at University of Illinois.

HEATING, HOT-WATER

Forced-Circulation System. Forced Hot-Water Circulation Heating System, Girard Estate, Philadelphia, Robert Hughes. Jl. Am. Soc. Heat & Vent. Engrs., vol. 27, no 2, Mar. 1921, pp. 107–108, 7 figs.

HEAVY-OIL ENGINES

Ingersoll-Rand. A New Development of the Heavy Oil Engine, F. A. McLean. Power House, vol. 14, no. 4, Feb. 20, 1921, pp. 26–29, 4 figs. Ingersoll-Rand, Price Rathbun type.

HELICOPTERS

Experimental. A Series of Flights Effected with Helicopter on the 15, 28 and 29 of Jan. 1921 (Une série de vols en helicoptère libre monté effectués les 15, 28 et 29 janvier 1921), Etienne OEhmichen. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 7, Feb. 14, 1921, pp. 366–368. Apparatus has two propellers about 21 ft. in diameter, rotating in opposite directions. Horsepower of engine is 25. In experiments helicopter was raised vertically up to height of 10 ft.

Military. A Helicopter for Military Purposes. Sci. Am., vol. 124, no. 9, Feb. 26, 1921, p. 173, 1 fig. Pescara helicopter being tried by French Military Commission. Each of two propellers comprises six spokes which carry wings of biplane design. Propellers revolve at 200 r.p.m.

HOBBING MACHINES

See GEAR CUTTING, Machines for.

HOISTING ENGINES

Mine. World's Largest Hoisting Engines, R. C. Demary. Nat. Engr., vol. 25, no. 3, Mar. 1921, pp. 108–111, 3 figs. Engines at Michigan mine 5300 ft. deep. Four steam cylinders, 36 in. x 72 in. driving 36-ft. diameter conical drum.

HOISTS

Electrically Operated. Marine Railways, C. B. Connely. Gen. Elec. Rev., vol. 24, no. 3, Mar. 1921, pp. 240–243, 8 figs. Typical installations of electric hoists at American drydocks.

Skip. Skip Hoisting for Coal Mines, Andrews Allen and John A. Garcia. Min. & Metallurgy, no. 170, Feb. 1921, pp. 35–36. Advantages of skip hoisting are: Hoisting capacity capable of taking care of all coal and rock that can be mined; smaller shaft; and large ratio of lading to gross weight.

Why Some Operators are Substituting Skips for Cages in the Hoisting of Coal, Andrews Allen and John A. Garcia. Coal Age, vol. 19, no. 11, Mar. 17, 1921, pp. 485–489, 4 figs. Modifications in design necessary where large coal must be produced. Paper read before Am. Inst. Min. & Metallurgical Engrs.

HOSE COUPLINGS

Air Brakes. Repairing Air-Brake Hose Connections, J. V. Hunter. Am. Mach., vol. 54, no. 9, Mar. 3, 1921, pp. 377–378, 6 figs. Pneumatic devices used at Decatur car shops of Wabash Railway Co.

HOUSING

Concrete Dwellings Ltd., Westminster. The "C. D. L." System of Concrete Construction. Concrete & Constructional Eng., vol. 16, no. 2, Feb. 1921, pp. 118–123, 7 figs. Solid walls, or hollow walls with concrete ties are constructed by means of traveling mold. In case of hollow-wall mold is provided with core; if solid wall is desired, core is absent.

Hayes, England. Concrete Cottage Building. Hayes Housing Scheme. Concrete & Constructional Eng., vol. 16, no. 2, Feb. 1921, pp. 105–111, 9 figs. Houses erected with solid concrete walls and timber shuttering.

Industrial, U. S. Housing by Employers in the United States, Leifur Magnusson. U. S. Dept. of Labor, Bur. of Labor Statistics, no. 263, Oct. 1920, 283 pp., 111 figs. Representative examples of manufacturing towns and mining communities.

HYDRAULIC TURBINES

Water Measurement. New Method of Water Measurement in Efficiency Tests of 37,500-hp. Turbines, N. R. Gibson. Power, vol. 53, no. 12, Mar. 22, 1921, pp. 452–458, 17 figs. Efficiency tests of three units in station of Niagara Falls Power Co. are described with particular reference to application of Gibson method and apparatus for measuring flow of water in penstocks. Paper read at joint meeting of Engrs. Club of Phila. & Phila. Sections of Am. Soc. Civil Engrs., Am. Inst. Elec. Engrs. & Am. Soc. Mech. Engrs.

New Method of Water Measurement in 37,500-hp. Turbine Tests. Elec. World, vol. 77, no. 11, Mar. 12, 1921, pp. 591–593, 8 figs. Discharge is measured by pressure developed in penstock when turbine gates are closed. Method has been applied at Niagara Falls.

Wheel for. New Type of Wheel for Hydraulic Turbine (Tipo nuevo de rueda para turbina hidràulica), Forrest Nagler. Ingenieria Internacional, vol. 5, no. 4, April 1921, pp. 206–208, 2 figs. Four-bladed propeller rotating at 50 r.p.m.

HYDROELECTRIC PLANTS

Austria. The Construction of the Power Station at Waterfalls on the Mur River (Austria) (Der Bau des Murfallwerkes), Otto Judtmann. Zeit. des Oesterr. Ingenieur- u. Architekten-Vereines, vol. 73, nos. 1–2, Jan. 14, 1921, pp. 5–6, 4 figs. Construction details of nearly completed light and power station begun in 1919.

Automatic. Automatic Hydroelectric Plants for Power and Lighting. T. A. E. Belt. Elec. Rev (Chicago), vol. 78, no. 11, Mar. 12, 1921, pp. 417–420, 5 figs. Types of control and regulating equipment available for use with stations operating without individual attendants.

Bavaria. Hydroelectric Development in Bavaria (Ueber den Ausbau der Wasserkräfte in Bayern), Phillip Forchheimer. Zeit. des Oesterr. Ingenieur-u. Architekten-Vereines, vol. 73, nos. 1–2, Jan 14, 1921, pp. 1–3. Summary of projects to be financed by State and private industries, totaling 223,700 hp., which is greatly in excess of total (112,838 hp.) already developed.

California. Hydro-Electric Plant Built in 15 Months, R. C. Starr. Elec. World, vol. 77, no. 9, Feb. 26, 1921, pp. 461–474, 8 figs. Methods that were employed to hasten 50,000-hp. Kerckhoff development (California) which was undertaken to relieve power shortage resulting from postponement of construction during war period.

Economical Operation. Note on a System for Accumulation of Energy Which Permits more Economical Operation of a Hydroelectric Central Station (Di un sistema di accumulazione d'energia, per una migliore utilizzazione delle centrali idroelectriche), Alfredo Mauceri. Elettrotecnica, vol. 8, no. 4, Feb. 5, 1921, pp. 73–75. Thermal electric installation at Olten, Switzerland.

England. The Lochaber Hydro-Electric Scheme. Engr., vol. 131, no. 340, Mar. 4, 1921, pp. 226–227, 2 figs. Scheme for production of from 70,000 to 75,000 hp. continuously.

Muscle Shoals. Completion of Muscle Shoals Plant Urged. Elec. World, vol. 77, no. 11, Mar. 12, 1921, pp. 587–590, 6 figs. Proposed dam and power house is structure 4200 ft. long situated on Tennessee River above Florence, Ala. As part of installation there will be locks providing for navigation past dam with total lift of 90 ft. above level of proposed lower pool.

Hydro-Electric Project at Muscle Shoals, A. S. McBride. Power, vol. 53, no. 11, Mar. 15, 1921, pp. 422–424, 3 figs. Five-hundred-thousand-horsepower project at Wilson Dam, to supply power at 4 mills per kilowatt-hour for continuous, and 1 2 mills for surplus, energy.

North Wales. Actual and Projected Water Power Developments in North Wales, John B. C. Kershaw. Engr., vol. 131, no. 3400, Feb. 25, 1921, pp. 195–198, 10 figs. Developments contemplated will furnish an additional 35,000 kw. at 34,600 volts.

Norway. The Hydro-Electric Power Scheme at the Nore Falls. Engineering, vol. 11, no. 2879, Mar. 4, 1921, pp. 248–249, 5 figs. Developments by Norwegian government of hydroelectric power scheme near Christiania. (To be continued.)

Pressure Shafts. The Calculation of Pressure Shafts (Zur Berechnung von Druckschächten), J. Büchi. Schweizerische Bauzeitung, vol. 77, nos. 6, 7 and 8, Feb. 5, 12 and 19, 1921, pp. 61–63, 73–76 and 88–91, 11 figs. Notes on investigation of an Austrian pressure shaft through rock, dealing with general construction procedure and the separate problems; calculation of influence of the internal water pressure; influence of contraction of the concrete, and of temperature; insufficient laying on of concrete; longitudinal and round joints; drainage of pipe; pressure of soil; rust deterioration; comparison of costs.

Weedon, P. Q. Hydro-Electric Plant at Weedon, P. Q., for City of Sherbrooks. Contract Rec., vol 35, no. 10, Mar. 9, 1921, pp. 229–230, 4 figs. Plant will develop 4000 hp. and deliver energy at 50,000 volts along transmission line 28 miles long.

I

ICE PLANTS

Electrically Operated. Electrically Operated Ice Plants, Reginald Trautschold. Refrigerating World, vol. 56, no. 3, Mar. 1921, pp. 12–13. Development of electric drive for ammonia compressors.

INDUSTRIAL MANAGEMENT

Administrative Research. Industrial Research in the Art of Man Management, Erwin H. Schell. Am. Mach., vol. 54, no. 9, Mar. 3, 1921, pp. 364–367. Administrative research recommended for standardization of policies. Questionnaire suggested.

Chemical Plants. Taking Industrial Chemistry Into Partnership—I, Frederic Dannerth. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 151–154. Standard practice for chemical industry process management.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 8, Jan. 25, 1921, p. 58. Proposal of the Committee for Economic Production for

instruction sheet for the ordering and delivery of machine tools.

Legislation. The Future of Industrial Management, F. M. Lawson. Jl. Royal Soc. of Arts, vol. 69, no. 3559, Feb. 4, 1921, pp. 164–171 and (discussion) pp. 171–175. Discusses enacting of future legislation for promotion of industrial peace.

Planning Departments. Practical Organization Principles, G. Sumner Small. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 183–186. Principles underlying practical organization of industrial departments.

Production Systems. Color Cycle Production Control, Carle M. Bigelow. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 168–170, 4 figs. Method adopted in knitted underwear plant.

Controlling the Flow of Production, H. K. Hathaway. Indus. Management, vol. 61, no. 5, Mar. 1 1921, pp. 175–179, 5 figs. How to keep track of split or broken lots on single route-sheet.

Increasing Production by a Rational Piece-Work System, John C. Spence. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 519–520. Experiences of manufacturers with piece-work system.

Modern Production Methods—XV, W. R. Basset. Am. Mach., vol. 54, no. 10, Mar. 10, 1921, pp. 398–402, 7 figs. Forms for accounting for supplies.

Production Methods of Rolls-Royce Plant. Iron Age, vol. 107, no. 9, Mar. 3, 1921, pp. 555–559, 4 figs. Experience of automobile factory built in America along lines of English works.

System for Production Control. Machy. (N.Y.), vol. 27, no. 7, Mar. 1921, pp. 647–650, 8 figs. Methods employed in plant of Am. Multigraph Co., for recording progress of work.

Safety. Safety Organization in Machine Shops. Eng. & Indus. Management, vol. 5, no. 8, Feb. 24, 1921, pp. 232–233. Safety organization of typical firm.

Safety Methods Applied in the Ryerson Steel-Service Plants. Chem. & Metallurgical Eng., vol. 24, no. 8, Feb. 23, 1921, pp. 351–354, 6 figs. Outline of general organization for safety promotion in plants and of results leading to better relationship between management and workers and to ultimate reduction of plant-operating costs and higher efficiency.

Shop Methods. Sharpening Up Dull Periods. Factory, vol. 26, no. 6, Mar. 15, 1921, pp. 718–723. From results of questionnaire to 325 plants asking them for description of their practices in slack times.

Storing Materials. Stores Engineering, M. T. Montgomery. Proc. Engrs. Soc. Western Pennsylvania, vol. 36, no. 10, Jan. 1921, pp. 641–673 and (discussion) pp. 674–682, 26 figs. Storekeeping practice of Pittsburgh Railways Co.

Systems. Idealism as a Factor in Management, Herbert Rollin White. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 165–167. Application of "golden rule" in industrial management. Examples of successful management.

Toolroom Organization. A Tool System That Speeds Production, William J. Burger. Factory, vol. 26, no. 4, Feb. 15, 1921, pp. 458–460, 6 figs. Toolroom organization of Warner & Swasey Co.

INDUSTRIAL RELATIONS

Department of. Industrial Relations Departments, James W. Brown. Foundry, vol. 49, no. 6, Mar. 15, 1921, pp. 229–231. Advantages derived from promoting family spirit in industrial life of employees. Paper read before Am. Foundrymen's Assn.

Open Shop. Twin Cities Team for Open Shop, A. J. Hain. Iron Trade Rev., vol. 68, no. 11, Mar. 17, 1921, pp. 762–768. Association organized by St. Paul Manufacturers to coöperate with Minneapolis Citizen's Alliance.

[See also TIME STUDY.]

Syndical Control, Italy. Syndical Control of Industries in Iatly (À propos du controle syndical des industries en Italie). Revue générale de l'Electricité, vol. 9, no. 9, Feb. 26, 1921, pp. 289–296. Text of projects submitted to Italian Government by Italian Federation of Intellectual Workers and by Italian General Federation of Industry, together with text of project devised by Italian Government.

INLAND NAVIGATION

Electric Hauling on Canals. New Systems of Electric Hauling on Canals (Nouveaux systèmes de halage électrique sur les canaux), Ed. Imbeaux. Nature (Paris), no. 2441, Jan. 15, 1921, pp. 33–37, 5 figs. Developments in France.

INSULATORS, HEAT

Tests. Heat Insulating Properties of Cork and Lith Board, A. A. Porter, J. P. Coulderwood, A. J. Mack and L. S. Hobbs. Power Plant Eng., vol. 25, no. 5, Mar. 1, 1921, pp. 285–286. 4 figs. Tests made in Engineering Experiment Station of Kansas State Agricultural College. Cork board showed heat insulating property approximately 5 per cent greater than lith board.

Relative Heat Conductivities of Some Insulating and Building Materials, James J. Lichtin. Chem. & Metallurgical Eng., vol. 24, no. 9, Mar. 2, 1921, pp. 388, 2 figs. Experimental measurements.

INTERNAL-COMBUSTION ENGINES

Efficiency Determination. Determination of the Mechanical Efficiency of Internal-Combustion Engines, V. L. Maleev. Gas Engine, vol. 23, no. 3, Mar. 1921, pp. 53–58, 7 figs. Type of brake constructed by writer for testing high-pressure Diesel engine of 140 b.hp.

Indicator Diagrams. A High-Speed Engine Pressure Indicator of the Balanced Diaphragm Type, H. C. Dickinson and F. B. Newell. Nat. Advisory Committee for Aeronautics, no. 107, 15 pp., 14 figs. Principle involved is balancing of engine cylinder pressure against measured pressure on opposite sides of metal diaphragm of negligible stiffness. Phase of engine cycle to which pressure measurement corresponds is selected by timing device.

Two-Stroke. The Record Two-Stroke Engine. Engr., vol. 121, no. 3402, Mar. 11, 1921, pp. 270–271, 2 figs. Absence of poppet valves is feature of internal-combustion engines manufactured by Record Eng. Co., London. Valves are replaced by arrangement of twin working pistons and piston valve, latter being operated by means of eccentric formed solid with crankshaft and being utilized for distributing explosive mixture to cylinders.

Water Coolers. The Heenan Water Cooler. Engineering, vol. 111, no. 2877, Feb. 18, 1921, p. 193, 6 figs. Cooler consists of single casting containing two vertical screens formed of brass or phosphor bronze, metallic wool and placed one behind the other. Water from engine jackets is distributed from troughs on top of cooler over screens through perforated brass plates, and is then recirculated by rotary pump.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; HEAVY-OIL ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES; TRACTOR ENGINES.]

J

JIGS

Manufacture. Building Jigs and Fixtures on Manufacturing Basis, W. H. Vockell and H. C. Uihlein. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 632–635, 11 figs. Standardization of details to permit production in quantity at reduced cost. Practice of Cincinnati Eng. Tool Co.

Using Compound Slide in Jig and Die Making. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 630–631, 4 figs. How Johansson compound slide is used in toolroom work, especially in laying out of accurately spaced holes.

L

LABOR

College Movement. What the Workers Want to Know, William Leavitt Stoddard. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 208–210. Objects and methods of labor college movement.

Hours of Work. Practical Experience With the Work Week of Forty-Eight Hours or Less. Nat. Indus. Conference Board, research report no. 32, Dec. 1920, 88 pp. Based on experience of manufacturers extending over varying periods. It was desired to determine whether or not 48 hr. schedule would yield the same, or practically the same, weekly output per worker as previous longer schedule in same plants and under substantially same conditions.

[See also INDUSTRIAL RELATIONS; INDUSTRY.]

LADLES

Stopper. Proved Design for Ladle Stopper. Foundry, vol. 49, no. 6, Mar. 15, 1921, pp. 219–222, 3 figs. Means provided for taking care of expansion of sleeve. Taper of bottom sleeve for acid practice.

LATHE TOOLS

Multiple Inserted Cutters. Efficiency Tests with Tools with Multiple Inserted Cutters (Leistungsversuche mit Stäblen mit mehrfacher Schneide), Hermann Brösamlen. Betrieb, vol. 3, no. 8, Jan. 25, 1921, pp. 213–215, 1 fig. Described tests show that by use of profile tools (Jäger tools, patented), an increase in production without increase of means of production can be obtained, due to the combined arrangement of the tools and especially to reduction of the unproductive working period.

LATHES

Bench. Tools and Methods for Manufacturing Precision Bench Lathes—I, Fred R. Daniels. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 668–672, 8 figs. Practice of S. A. Potter Tool & Machine Works, New York City, in manufacture of bench lathes.

Cadillac. The Cadillac Vertical Lathe, J. V. Hunter. Am. Mach., vol. 54, no. 12, Mar. 24, 1921, pp. 489–491, 5 figs. Semi-automatic compact machine intended for single-purpose work.

Lead-Screw Variator. Lathe Lead Screw Variator Device. Iron Age, vol. 107, no. 9, Mar. 3, 1921, pp. 569, 2 figs. Device consists of bracket unit clamped to ways of lathe, lead-screw mechanism and rods connecting variator nut with lathe carriage. Manufactured by Precision & Thread Grinder Mfg. Co., Philadelphia.

Stud and Bolt. Automatic Stud and Bolt Machine. Engineering, vol. 111, no. 2879, Mar. 4, 1921, pp. 252, 5 figs. Machine designed for straight forward stud and bolt work. Machine is provided with automatic chuck for machining bolts $1^1/_2$ in. in diameter; range of studs dealt with is from $^1/_2$ in. to $1^1/_4$ in., with maximum length of 9 in.

Turret. Obtaining Production on the Vertical Turret Lathe. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 534–540, 18 figs. Application of Bullard vertical turretlathe to machine-shop practice, including typical examples and description of tooling used.

Turret Lathe Applications, J. H. Moore. Can. Machy., vol. 25, no. 6, Feb. 24, 1921, pp. 38–41, 16 figs. Tooling necessary for machining axle housing, motor frame, and piece of work weighing over 600 lb.

LIGHTING

Illumination Standards. Practical Illumination Design Method and Data, Earl A. Anderson. Elec. Rev. (Chicago), vol. 78, no. 11, Mar. 12, 1921, pp. 411–415, 8 figs. Table giving present standards for illumination for various services. (To be continued.)

Industrial. Industrial and Factory Lighting. Jl. Electricity & Western Industry, vol. 46, no. 4, Feb. 15, 1921, pp. 186–187, 4 figs. Investigation in 446 industrial plants brought out that average of approximately 25 per cent of work done is carried on under artificial illumination.

The Human Factor in Industrial Lighting, James R. Cravath. Jl. Electricity & Western Industry, vol. 46, no. 4, Feb. 15, 1921, pp. 181–183, 2 figs. Tests showing effect of improved artificial lighting on output in number of industrial plants.

LIGNITE

Briquetting. The Manufacture of Lignite Briquettes. Eng. Progress, vol. 2, no. 2, Feb. 1921, pp. 25–28, 7 figs. Description of briquetting factory.

Drying. Lignite (Le lignite), Jean C. Verdier. Revue de l'Ingenieur, et Index Technique, vol. 28, no. 1, Jan. 1921, pp. 9–16, 4 figs. Formula and graph for determining quantity of water to be removed by grinding. (Continuation of serial.)

LOCOMOTIVE BOILERS

Insulation. The Insulation of Locomotive Boilers, Wm. N. Allman. Ry. Rev., vol. 68, no. 10, Mar. 5, 1921, pp. 349–350, 2 figs. Efficiency curves of 85 per cent magnesia lagging.

LOCOMOTIVES

Electric. See ELECTRIC LOCOMOTIVES.

European Designs. Recent Trend in Locomotive Design in Europe. Mech. Eng., vol. 43, no 3, Mar. 1921, pp. 189–192, 8 figs. Three-cylinder fast-freight locomotive in operation in English railway, and German internal-combustion mine locomotives.

Feedwater. See BOILER FEEDWATER, Treatment.

Freight, Tests. Design and Tests of Freight Locomotives on the Pennsylvania Railroad, Lawford H. Fry. Engineering, vol. 111, no. 2877, Feb. 18, 1921, pp. 190–191, 2 figs. Graphs showing speed and drawbar pull of various types. (To be continued.)

Fuel Consumption. Train Schedules and Locomotive Fuel Consumption, Edwin Winfield. Can. Ry. & Mar. World, no. 277, Mar. 1921, pp. 124–126, 4 figs. Graphs indicating variation in coal consumed with power exerted.

Oil-Burning. Results of Traction Tests of Locomotives Equipped for Burning Oil (Risultati degli esperimenti e delle prove di trazione eseguite con alcune locomotive attrezzate per bruciare la nafta nei forni delle loro caldaie), Alessandro Mascini. Rivista tecnica delle Ferrovie Italiane, vol. 18, no. 5, Nov. 15, 1920, pp. 161–189, 5 figs. Experiments conducted by Italian State Railways. (Concluded.)

Pulverized-Coal-Burning. Locomotive Burning Pulverized Coal (L'application du charbon pulverisé aux locomotives) Outillage, vol. 5, no. 4 Jan. 27, 1921, pp. 98–101, 50 figs. Italian locomotives equipped to burn pulverized lignite, also Swedish locomotives with Fuller system for burning pulverized peat.

Shop Equipment. Locomotive Shop Equipment on Wheels. J. V. Hunter. Am. Mach., vol. 54, no. 10, Mar. 10, 1921, pp. 403–404, 6 figs. Locomotives transferred to repair pits by traveling crane. Time saved by taking portable workbenches and machine tools to work.

Superheaters, Schmidt. The New Tender Locomotives of the Danish State Railroad with Narrow-Tube Superheaters (Statsbanernes nye Tenderlokomotiver med Smaarörsoverheder). Ingenioren, vol. 30, no. 1, Jan. 1, 1921, p. 3. Locomotives (switchers) are provided with the Schmidt system of smoke-tube superheaters consisting partly of enlarged and partly of narrow fire tubes.

LUBRICATING OILS

Centrifugal Cleaner. Centrifugal Oil Cleaner. Oil News, vol. 9, no. 4, Feb. 20, 1921, pp. 21–22, 2 figs. Apparatus under development at McCook Field. Oil is led from oil tanks to inside of bowl which is rotating at 2550 r.p.m. when engine is turning up 1700 r.p.m.

Dilution. Dilution of Crankcase Oil, Wm. F Parish. Jl. Soc. Automotive Engrs., vol. 8, no. 3, Mar 1921, pp. 231–237 and 254. 3 figs. Results of tests made on aeroplane engines to determine effect of dilution of crankcase oil. Comparative characteristics of used and reclaimed oil. Paper read before Am. Petroleum Inst.

Selection. Friction and Fuel, Wm. N. Berkeley. Power, vol. 53, no. 10, Mar. 8, 1921, pp. 390–392. Comparison of constants of asphalt-base and paraffin-base lubricating oils. Table indicating best uses for different classes of lubricating oils.

M

MACHINE SHOPS

Layout. New Plant of the Foote-Burt Company. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 528–530, 6 figs. Features of modern factory planned with view to convenient handling and progressive routing of work.

MACHINE TOOLS

Duplicating Machines. The Manufacture of Duplicating Machines. Eng. Production, vol. 2, no. 22, Mar. 3, 1921, pp. 289–294, 16 figs. Manufacturing methods employed in Roneo Works, London.

German. German Machine Tools. Eng. & Industrial Management, vol. 5, no. 6, Feb. 10, 1921, pp. 174–175. Report of general meeting of British Machine Tool Trades Assn. giving arguments for and against handling of German machine tools in England.

Heavy. Some Examples of Heavy Modern Machine Tools, K. Ehmcke. Eng. Progress, vol. 2, no. 2, Feb. 1921, pp. 33–38, 15 figs. Giant portal-type milling machine with two vertical spindles and four horizontal boring and milling machines; giant milling machine with three double spindles and seven electromotors; lathe with 8.5 ft. height of centers; vertical lathe for turning diameter of 39.4 ft.

Spacing Tables. Improved Design of Spacing Table. Iron Age, vol. 107, no. 11, Mar. 17, 1921, pp. 707, 3 figs. Semi-automatic machine manufactured by Cleveland Punch & Shear Works Co.

Special-Purpose. Special Machines and Tools in the Chandler Plant. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 565–568, 6 figs. Equipment used by Chandler Motor Car Co., Cleveland, Ohio, for milling crankcases, boring and reaming crankshaft and camshaft bearings, and numerous other operations.

Variable-Speed Motors for. Machine Tools and Variable-Speed Motors (Werkzeugmaschine und Reguliermotor), Othmar Pollok. Werkstattstechnik vol. 15, no. 4, Feb. 15, 1921, pp. 81–85, 7 figs. Their use in connection with large and small machine tools. Direct-current versus 3-phase-current variable-speed motors.

MACHINERY

Manufacture. Building Heavy Machinery. Eng. Production, vol. 2, no. 23, Mar. 10, 1921, pp. 321–325, 6 figs. Works and methods of Hick, Hargreaves, England, manufacturers of locomotives, marine engines, Lancashire and other type boilers, stationary engines of all classes, water turbines and mill-gearing.

MALLEABLE IRON

Experiments. Experiments in Malleable Iron, F. H. Hurren. Foundry Trade Jl., vol. 23, no. 234, Feb. 10, 1921, pp. 125–128 and (discussion) pp. 136–138, 6 figs. Analyses of samples and photomicrographs.

Foundries. Equips for Malleable Jobbing Work, H. E. Diller. Foundry, vol. 49, no. 5, Mar. 1, 1921, pp. 171–175, and 185, 8 figs. Foundry at Temple, Pa., where $2^1/_2$ lb. of castings are annealed with 1 lb. of coal.

Strength of. American Malleable Cast Iron—V, H. A. Schwartz. Iron Trade Rev., vol. 68, no. 9, Mar. 3, 1921, pp. 628–631 and 633. Stress-strain diagrams of malleable cast iron in compression and in shear.

METALS

Thermal Capacities. Heating Furnaces and Annealing Furnaces, W. Trinks. Forging & Heat Treating, vol. 7, no. 2, Feb. 1921, pp. 109–111, 4 figs. Graph showing heat content of pure metals at various temperatures, constructed from figures obtained in experiments conducted by the Society of German Engineers.

METRIC SYSTEM

Arguments Against Adoption in United Kingdom. Scientific England and the Metric System. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, p. 154. Abstract of report submitted by Metric Committee appointed by conjoint board of Scientific Societies of United Kingdom. It is recommended that British system of units of weights and measures be retained in general use in United Kingdom.

Arguments Against Adoption in U. S. The Metric Equivalent Scheme, Frederick A. Halsey. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 665–667, 1 fig. Arguments against contention of T. H. Miller in Machinery 1920 that it is feasible to adopt metric measurements for machines already being manufactured in English units.

MILLING MACHINES

Fixtures. Milling Machine Methods. Eng. Production, vol. 2, no. 23, Mar. 10, 1921, pp. 330–331, 11 figs. Typical fixtures designed for production milling.

MOLDING MACHINES

Pneulec Electrically Operated. The "Pneulec" Moulding Machine. Foundry Trade Jl., vol. 23, no. 232, Jan. 27, 1921, p. 76, 1 fig. Electrically operated machine which can simply be placed on firm foundation and connected up to nearest electric supply main; it is said to be possible to obtain between 40 to 210 molds per day.

Squeezer Machine. Invents a New Type of Squeezer Machine. Foundry, vol. 49, no. 6, Mar. 15, 1921, pp. 249–250, 1 fig. Patented machine operated by compressed air.

MOLYBDENUM STEEL

Tests. A Discussion of Molybdenum Steels, Charles McKnight. Trans. Am. Soc. for Steel Treating, vol. 1, no. 6, Mar. 1921, pp. 288–296. Tensile tests of molybdenum steels.

Uses. Molybdenum Steels, John A. Matthews. Chem. & Metallurgical Eng., vol. 24, no. 9, Mar. 2, 1921, pp. 395–396. Also Min. & Metallurgy, no. 170, Feb. 1921, pp. 39–40. Development of molybdenum steel in America. Early experiments with this element in complex alloys for tools. Recent successful utilization in mechanical and structural steels of high strength and great adaptability.

MORTARS

Cement, Shrinkage. Shrinkage of Portland Cement Mortars and Its Importance in Stucco Construction. J. C. Pearson, Eng. & Contracting, vol. 55, no. 8, Feb. 23, 1921, pp. 187–190, 6 figs. Results of measurements on about 200 mortar slabs. Investigation conducted at U. S. Bur. of Standards. Paper read before Am. Concrete Inst.

MOTOR TRUCKS

Farm Service. Corn-Belt Farmers' Experience with Motor Trucks, H. R. Tolley and L. M. Church. U. S. Dept. Agriculture, bul. no. 931, Feb. 25, 1921, 34 pp., 3 figs. Study of 831 reports from farmers who own motor trucks.

MOTORSHIPS

Steamships vs. Advantages of Motorships Compared with Steamships. Motorship, vol. 6, no. 3, March 1921, pp. 210–211, 1 fig. Saving in space, which amounts to 30 per cent for machinery alone in favor of Diesel plant; saving of fuel, figures for motorship being about 0.33 lb. per i.hp. per hr., and for geared turbines steamship seldom below 0.990 lb. per i hp. per hr.; no standby losses in motorships; and less cost for cleaning and repairs in motorship.

N

NICKEL

Wire. The Change in the Rigidity of Nickel Wire with Magnetic Fields, William Brown and Patrick O'Callaghan. Sci. Proc. Royal Dublin Soc., vol. 16, no. 8, Aug. 1920, pp. 98–104, 2 figs. Records of measurements. Initial increase in rigidity of nickel was less for alternating than for direct longitudinal magnetic fields, while subsequent decrease was greater for alternating longitudinal fields than for direct fields.

NICKEL STEEL

Tests. Static and Dynamic Tension Tests on Nickel Steel, J. J. Thomas and J. H. Nead. Min. & Metallurgy, no. 170, Feb. 1921, p. 34. Relation between static and dynamic tension tests as measured by work required to break test specimens slowly in tensile testing machine, and rapidly, by means of falling weight. (Abstract.)

NOZZLES

Diesel-Engine. Nozzle Design for Diesel Engines—Influence of Air Pressure and Engine Speed, J. A. Wallard. Power, vol. 53, no. 12, Mar. 22, 1921, pp. 469–471, 2 figs. Effect of variable load and speed.

Losses in. On the Losses in Convergent Nozzles, A. L. Mellanby and Wm. Kerr. North-East Coast Instn. Engrs. & Shipbuilders (advance paper), 40 pp., 22 figs. Investigation of results given for convergent nozzle types in Pressure Flow Experiments on Steam Nozzles, Proc. Inst. Engrs. and Shipbuilders in Scotland, Nov. 16, 1920, and account of results obtained in further tests on steam nozzles. Empirical formula for total loss at any point along jet within boundary form is developed.

Tests. Pressure-Flow Experiments on Steam Nozzles, A. L. Mellanby and William Kerr. Engineering, vol. 111, no. 2879, Mar. 4, 1921, pp. 269–274, 20 figs. Determination of pressure at various points of nozzle by means of "search tube" moved along jet. Paper read before Instn. Engrs. & Shipbuilders in Scotland.

O

OIL

Distillation. A New Oil Distilling Process. Petroleum Times, vol. 5, no. 110, Feb. 12, 1921, p. 185. Process of mineral-oil distillation under high vacuum by means of which mineral oils or heavy mineral-oil residues are distilled non-destructively to solid coke. Process was developed by Leo Steinschneider, Bruenn-Koenigsfelder Maschinenfabrik, Czecho-Slovakia.

[See also PETROLEUM.]

OIL ENGINES

Cold-Starting. Cold-Starting Oil Engine. Gas Engine, vol. 23, no. 3, Mar. 1921, pp. 73–74, 2 figs. Fuel consumption curves of 250 b.hp. twin-cylinder Ruston high-compression oil engine.

Hot-Bulb. A Six-Cylinder Hot Bulb Engine. Engr., vol. 131, no. 3400, Feb. 25, 1921, pp. 212–214, 4 figs. Marine engine of 450 b.hp. constructed by Vickers-Peters, Ipswich, England.

OIL FIELDS

Borneo. The Sanga Sanga Oil Field of Borneo, W. H. Emmons and J. W. Gruner. Eng. & Min. Jl., vol. 111, no. 10, Mar. 5, 1921, pp. 431–432, 2 figs. Production in 1911 was 495,124 tons.

Exploitation by Shafts and Galleries. Working Petroleum by Means of Shafts and Galleries, Paul deChambrier. Petroleum Times, vol. 5, no. 111, Feb. 19, 1921, pp. 209–211, 1 fig. Practice at Pechelbronn, Alsace. Economical advantage of method. (Abstract.) Paper read before Instn. Petroleum Technologists.

OIL FUEL

Bunkering Station. Oil Fuel Bunkering Station at Marseille (Installation d'un dépot de mazout a Marseille). Bulletin technique de Bureau Veritas, vol. 3, no. 2, Feb. 1921, pp. 36–37, 1 fig. Details of discharging and pumping station. English test is given on page 38.

Burners. The Fisher Oil Fuel Burner. Engineering, vol. 111, no. 2878, Feb. 25, 1921, p. 225, 4 figs. U. S. Navy design intended to maintain whirling motion of liquid fuel over wide range of consumption.

Industrial Uses. Heating by Fuel Oil for Manufacturing Processes, C. C. Hermann. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 199–202. Advantages and limitation of oil fuel for industrial uses, particularly in use in forge-shop and heat-treating furnaces. Methods of purchasing, testing and storing fuel. Example illustrating how air capacity is determined for given service.

Measurement. Measurement of Fuel Oil, J. D. Gilman. Mar. Eng., vol. 26, no. 3, Mar. 1921, pp. 234–237. Tables for reducing measurement to standard conditions.

Specifications. The Saybolt Furol Viscosimeter, E. W. Dean. Reports of Investigations, Bur. of Mines, Dept. of Interior, Feb. 1921, serial no. 2215, 4 pp. Apparatus employed by Bureau of Mines in determining quality of oil fuel as required by specifications issued by U. S. Navy. Superiority of defining oil fuel in terms of viscosity rather than gravity is concluded from results of inspection work undertaken for U. S. Shipping Board.

Uses. Fuel Oil Burning in Various Parts of the World, Andrew F. Baillie. Jl. Royal Soc. of Arts, vol. 69, no. 3563, Mar. 4, 1921, pp. 232–243 and (discussion) pp. 243–246. Survey of uses, and records of comparative tests with coal and oil in similar boilers.

OIL SHALES

Pennsylvania. See COAL DEPOSITS, Pennsylvania.

Pyrolytic Distillation. Plant Design for Hot-Gas Pyrolytic Distillation of Shale, Louis Simpson. Chem. & Metallurgical Eng., vol. 24, no. 8, Feb. 23, 1921, pp. 341–345, 2 figs. Description and plan of 2000-ton-per-day shale-oil plant operating on indirect heating process employing hot gases for conveying reacting heat and resultant oil vapors from pyrolysis of shale.

Spent Shale, Uses of. Possible Uses for the Spent Shale from Oil Shale Operations, Kirby Thomas. Chem. & Metallurgy Eng., vol. 24, no. 9, Mar. 2, 1921, pp. 389–390. Uses as fuel, as non-conductor material for electrical applications and as material for making brick.

Utilization. Some Items of Investment, Expense, and Profit in Commercial Shale-Oil Production, L. H. Sharp and A. T. Strunk. Reports of Investigations, Bur. of Mines, Dept. of Interior, Feb. 1921, serial no. 2214, 3 pp. Equipment necessary for large-scale commercial utilization of oil shales.

P

PEAT

Use on Swedish Railways. Peat Proves Satisfactory Fuel on Swedish Railways. Commerce Reports, no. 46, Feb. 25, 1921, p. 1109. Peat is dried in open air and softest lumps are converted into powder or briquets. Tests have passed experimental stage and Railway Board of Sweden has constructed plant with capacity of 30,000 tons per annum.

PETROLEUM

World Production. World's Production of Petroleum. Eng. & Min. Jl., vol. 111, no. 10, Mar. 5, 1921, pp. 433. Production in 1920 was 688,474,251 barrels against 554,505,048 barrels in 1919. In 1920 the United States supplied 443,402,000 barrels.

[See also OIL.]

PHOTO-ELASTICITY

Uses in Machine Design. Photo-Elasticity for Engineers—The Use of Photo-Elastic Methods in the Design of the Elements of Machines and Structures, E. G. Coker. Gen. Elec. Rev., vol. 24, no. 3, Mar. 1921, pp. 222–226, 5 figs. Procedure suggested and illustrated by application to design of eye bars

PISTONS

Inspection. Inspecting Pistons and connecting Rods, Fred H. Colvin. Am. Mach., vol. 54, no. 10, Mar. 10, 1921, pp. 407–410, 14 figs. Importance of inspection methods to quality of product. Methods in use on Essex and Studebaker pistons and connecting rods.

Manufacture. Manufacture of the Jahns Semi-Finished Pistons. Metal Trades, vol. 12, no. 3, Mar. 1921, pp. 95–97, 10 figs. Practice at Los Angeles plant.

PLANING

Production Systems. Production Planing in Machine Tool Plants, Edward K. Hammond. Machy. (N. Y.), vol. 27, nos. 6 and 7, Feb. and Mar. 1921, pp. 552–559, 8 figs., and 659–664, 8 figs. Methods used in shops of representative engine-lathe and planer builders.

Production Planing in Machine Tool Plants. Machy. (London), vol. 17, nos. 438 and 440, Feb. 17 and Mar. 3, 1921, pp. 597–604, 13 figs., and 680–684, 5 figs. Planer practice in a number of plants building milling machines and lathes.

PLYWOOD

Tests. Strength Tests of Screw Fastenings of Plywood, H. S. Grenoble. Aviation, vol. 10, no. 8, Feb. 21, 1921, pp. 230. Tests conducted at Forest

ENGINEERING INDEX (Continued)

Products Laboratory, U. S. Forest Service, Madison, Wis. Size and kind of screw, use of washers, margin, spacing and species of plywood and of member to which fastening was made, were included.

PNEUMATIC TOOLS

Manufacture. The Manufacture of Pneumatic Tools. Machy. (London), vol. 17, no. 439, Feb. 24, 1921, pp. 636–645, 22 figs. Review of methods employed by Consolidated Pneumatic Tool Co., Scotland.

PORTS

New York. Plans for Organizing the Port of New York. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 211 and 220, 1 fig. Automatic electric subway to eliminate surface congestion and reduce handling cost. Report presented to governors of New York and New Jersey by New York-New Jersey Port and Harbor Commission.

POWER

Industrial Supply. Industry's Supply of Energy, George Otis Smith. Mech. Eng., vol. 43, no. 3, Mar. 1921, pp. 165–166 and 188. Survey of available supplies of coal, oil, and water, together with discussion of engineer's part in economic and efficient utilization of energy units.

POWER PLANTS

Helgoland Island. Power Stations with Diesel Engines on Helgoland Island (Kraftwerke mit Dieselmotoren auf der Insel Helgoland), H. Methling. Schiffbau, vol. 22, no. 16, Jan. 19, 1921, pp. 363–366, 6 figs. The two stations, supplying power, light and ventilation to all the plants and buildings of fortification works, are provided with five pumping works driven by Diesel engines of 345 hp. at 165 revolutions, besides which there are three Diesel dynamos, etc.

POWER TRANSMISSION

Hydraulic. Hydraulic Transmission of Power (La transmission hydraulique), A. Raudot. Revue générale de l'Electricité, vol. 9, nos. 6, 8 and 9, Feb. 5, 19 and 26, 1921, pp. 177–181, 18 figs., 239–243, 4 figs., and 279–284, 5 figs. System involving generator pump on rotary type with fixed cylinders arranged in star shape. Suggested design of 12-cyl. generating pump. Comparative study of characteristics of hydraulic and electric motion. Application of hydraulic transmission to railway traction.

PRESSWORK

Pressed-Steel Parts. Making Pressed Metal Parts Becomes Important Industry, E. L. Shaner. Iron Trade Rev., vol. 68, no. 9, Mar. 3, 1921, pp. 617–620, 6 figs. Development of manufacture of pressed steel in the United States.

PROFIT SHARING

Legal Aspect. Profit Sharing in Industry (La participation ouvrière aux bénéfices de la production), Paul Razous. Génie Civil, vol. 78, no. 4, Jan. 22, 1921, pp. 84–87. Arguments against legal compulsion of management to establish profit-sharing system. (Concluded.)

Norway. A Norwegian Plan for Profit Sharing. Monthly Labor Rev., vol. 12, no. 2, Feb. 1921, pp. 117–119. Plan worked out by Council of Nat. Workingmen's Assn., Norway.

Plans for. Encouraging Industrial Coöperation, A. H. Dittmer. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 549–551, 2 figs. Credit point system operated at plant of Dittmer Gear & Mfg. Corp., Lockport, N. Y.

PROPELLERS, SHIP

Erosion. The Erosion of Bronze Propellers, O. Silverrad. Jl. Soc. Chem. Industry, vol. 40, no. 4, Feb. 28, 1921, pp. 38T–45T, 8 figs. Also Shipbuilding & Shipping Rec., vol. 17, no. 7, Feb. 17, 1921, p. 183. Investigations into cause of deterioration. It is concluded that true cause of deterioration is mechanical, determining factors being frictional rub of water and impinging on propeller blades of water broken with evacuated spaces which subsequently collapse on propeller blades. Formation of erosion-resisting alloy.

Manufacture. The Manufacture of High-Class Marine Propellers. Eng. Production, vol. 2, no. 20, Feb. 17, 1921, pp. 227–236, 15 figs. Procedure at Charlton Works of J. B. Stone & Co., England. Paper read before Inst. of Mar. Engrs.

PULLEYS

Standard. Standard Belt Pulley, Chris Nyberg. Agricultural Eng., vol. 2, no. 1, Jan. 1921, p. 21, 1 fig. Chart for solution of pulley-spoke dimensions.

Standardization of Diameters. Standardization of Pulley Diameters (Normung der Riemenscheibendurchmesser), Ludwig Gück. Werkstattstechnik, vol. 15, no. 4, Feb. 15, 1921, pp. 87–90. Standardization of diameters based on standardized speeds which are presented in tabular form.

PULVERIZED COAL

Uses. A Series of Discourses on Use of Powdered Anthracite and Recovery and Use of River Coal, George H. Ashley, C. W. Webbert, Jonathan P. Edwards, G. R. Delamater, W. S. Guigley, Richard H. Vail, J. R. Wyllie, J. H. Kennedy, W. W. Pettibone and H. D. Savage. Jl. Engrs Club of Phila., vol. 38, no. 194, Feb. 1921, pp. 39–63, 8 figs. Statements by geological and mining authorities and engineers on best methods of pulverizing anthracite coal, together with results of boiler fires made at pulverized fuel plant at Lykens, Pa.

PUMPS

Humphrey. The Humphrey Pump. Engr., vol. 131, no. 340, Mar. 4, 1921, pp. 232 and 238, 4 figs. Installation of Humphrey pumps for Metropolitan Water Board at Chingford. Record of efficiency tests.

Lubricator for. A New Pump Lubricator. Engr., vol. 131, no. 3398, Feb. 11, 1921, p. 161, 2 figs. Prevention of airlock in oil passages when starting up is feature.

PUMPS, CENTRIFUGAL

Gasoline-Engine Drive. Gasoline-Engine Drive for Centrifugal Pumps, T. M. Heermans. Power, vol. 53, no. 10, Mar. 8, 1921, pp. 376–377, 5 figs. Types of engines used. Curves show that engine horsepower should be 25 per cent greater than water horsepower required.

PUNCHING MACHINES

Standardization. Power Punches and Dies. Ry. Jl., vol. 27, no. 3, Mar. 1921, pp. 13–16, 2 figs. Discussion of standardization of punching machines at Am. Ry. Tool Foremen's convention.

R

RADIOMETALLOGRAPHY

Examining Materials. X-Ray Examination of Materials, J. R. Clarke. Beama, vol. 8, no. 2, Feb. 1921, pp. 125–132. Experience obtained in research department of Metropolitan-Vickers Electrical Co., England.

RAILS

Manufacture. Steel Rails, C. W. Gennet, Jr. Jl. Western Soc. Engrs., vol. 26, no. 3, Mar. 1921, pp. 77–85. Comparative study of various processes for manufacturing steel rails.

Sink-Head Ingots. Steel Rails from Sink-Head and Ordinary Rail Ingots, Geo. K. Burgess. Dept. of Commerce, Technologic Papers of Bur. of Standards, no. 178, Dec. 15, 1920, 61 pp., 23 figs. Results obtained in experiments indicated decided superiority of sink-head ingots over ordinary ingots as made of three grades of steel.

RAILWAY ELECTRIFICATION

Chicago. The Illinois Central Electrification Project. Elec. Traction, vol. 17, no. 1, Jan. 1921, pp. 1–5, 4 figs. Ordinance regarding electrification of Chicago Terminals of Illinois Central Railroad was passed by Chicago city council July 21, 1919, and accepted by Illinois Central Railroad Co., Feb. 20, 1920. Details of project.

Europe. Electrification in Central Europe, E. C. Zehme. Elec. Ry. Jl., vol. 57, no. 10, Mar. 5, 1921, pp. 438–440. Résumé of conditions in Germany, Sweden, Norway, Holland and Italy.

Status of Foreign Electrification, E. C. Zehme. Elec. World, vol. 77, no. 10, Mar. 5, 1921, pp. 527–529. Developments in Germany, Austria, Sweden, Norway, Holland, Switzerland and Italy.

Sweden. The Electrification of the Swedish State Railways (L'électrification des chemins de fer de l'état suédois), M. Marchand. Industrie Electrique, vol. 30, no. 688, Feb. 25, 1921, pp. 68–72. Technical comparison of direct-current system with single-phase alternating-current system. Conditions in Sweden.

RAILWAY OPERATION

Economics. Report of Committee XXI—On Economics of Railway Operation. Bul. Am. Ry. Eng. Assn., vol. 22, no. 234, Feb. 1921, pp. 723–791, 13 figs. Methods for increasing efficiency of employees by furnishing them with reports and comparisons planned to inform and interest all concerned. Methods for increasing traffic capacity of railway, including analyses of costs and study of effect of speed of trains upon cost of operation.

RAILWAY REPAIR SHOPS

Design. A New Type of Erecting Aisle Saves Shop Headroom. Ry. Age, vol. 70, no. 9, Mar. 4, 1921, pp. 521–522, 3 figs. "Gap crane" erecting shop by which from 15 to 18 ft. of vertical height of shop building is saved.

RAILWAY TIES

Life. Tie Renewals in Relation to Average Life. Technical Note no. 130, Forest Products Laboratory, U. S. Forest Service, 2 pp., 1 fig. Comparisons of 43 groups included 42,000 ties of many species, some untreated and some treated.

Pneumatic Tamping. Determining the Cost of Pneumatic Tie Tamping. Ry. Maintenance Engr., vol. 17, no. 3, Mar. 1921, pp. 105–106. Records of tests conducted by Delaware, Lackawanna & Western Railroad.

Standards. Standard Specifications for Ties. Ry Rev., vol. 68, no. 9, Feb. 26, 1921, pp. 327–328. Specifications adopted by Nat. Assn. of Railroad Tie Producers, Jan. 18, 1921.

RESEARCH

Industrial. Industrial Research. Iron Age, vol. 107, no. 10, Mar. 10, 1921, p. 638. Program being carried out by Engineering Foundation. Industrial research on nation-wide scale, in which engineering organizations, universities, factories, individuals and private laboratories and other organizations are coöperating is under way. From annual report of Engineering Foundation.

The origin and Development of the Research Associations Established by the Department for Scientific and Industrial Research, A. Abbott. Jl. Royal Soc. of Arts, vol. 69, no. 3561, Feb. 18, 1921, pp. 181–205. Department has so far approved and licensed 23 industrial associations.

ROLLING MILLS

Universal Plate. New Universal Plate Mill, J. H. Moore. Can. Machy., vol. 25, no. 9, Mar. 3, 1921, pp. 65–69, 7 figs. Installation of Dominion Foundries & Steel, Ltd., at Hamilton, Ont. Mill will roll universal plate from 7 in. to 41 in., shear plate to 64 in., and will also roll slabs and billets.

Weirton, West Va. Rolling Mills of the Weirton Steel Co. Iron Age, vol. 107, no. 11, Mar. 17, 1921, pp. 693–702, 9 figs. Compact arrangement of 40-in. blooming mill with two Morgan continuous mills, 21-in. and 18-in., for producing sheet bars, billets and slabs.

ROOFS

Sawtooth. A New Type of Saw-Tooth Construction. Manufacturers Rec., 79, no. 10, Mar. 10, 1921, pp. 95–96, 3 figs. Super-span construction devised by Ballinger Co., Phila.

S

SAFETY

Bureau of Mines Schedules. Permissible Schedules Issued by the Bureau of Mines, L. C. Ilsley. Reports of Investigations, Bur. of Mines, Dept. of Interior, Feb. 1921, serial no. 2211, 3 pp. List of active schedules available to manufacturers. Schedules establish minimum standards for safety and details of test methods in manufacture of explosives, electric motors, safety lamps, mine-rescue apparatus, storage-battery locomotives, etc.

SAND BLAST

Apparatus and Uses. Sand-Blast Apparatus (Sandstrahlgebläse), Wilhelm Kaempfer. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 7, Feb. 12, 1921, pp. 175–178, 16 figs. Their use during war; sand blasts with rotary table and revolving drum; free-jet blasts; special constructions for cleaning of shells, removal of hammer scale from steel helm, etc., sheet-metal and structural-steel sections. Possible peace-time uses.

SANDING MACHINES

Economical Speeds. Determine Economical Sanding Speeds, James F. Adams. Abrasive Industry, vol. 2, no. 2, Feb. 1921, pp. 52–53, 2 figs. Curves constructed from results of sanding tests.

SCHOOLS

Industrial. A University in an Industry, Edwin Kurtz. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 191–193. Mutual university conducted by 6500 employees of Milwaukee Elec. Ry. & Light Co.

The Works School Exhibition of the German Committee for Technical Instruction in the Technical Academy, Berlin (Die Werkschulausstellung des Deutschen Ausschusses für Technisches Schulwesen in der Technischen Hochschule zu Berlin) H. Trost. Betrieb, vol. 3, no. 8, Jan. 25, 1921, pp. 21–26, 4 figs. Notes on exhibits from the apprentice schools of the Augsburg-Nürnberg Machine Factory (MAN); A. Borsig, Berlin-Tegel; German General Electric Co. (AEG); Bergmann Electrical Works, the Siemens concerns, etc.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREW MACHINES

Automatic. Magazine Feeds for Automatic Screw Machines. Machy. (N. Y.), vol. 27, no. 7, Mar. 1921, pp. 617–622, 10 figs. Equipments developed by Cleveland Automatic Machine Co., for handling second-operation work.

Straight Forming Tools. Dimension of Straight Forming Tools. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 560–564, 1 fig. Table giving depth of steps on straight forming tools measured at right angles to front face, corresponding to various differences between radii on work.

SEMI-DIESEL ENGINES

Air Admission. New Type of Mechanism for Air Admission in Semi-Diesel Motor (Nouveau type de commande d'admission d'air dans les moteurs semi-Diesel). Génie Civil, vol. 78, no. 7, Feb. 12, 1921, pp. 160, 1 fig. Rotary valve controls admission of air into cylinder in semi-Diesel engine manufactured by Ansald San Giorgio Corp.

SEMI-STEEL

Cast Iron vs. Cast-Iron vs. Semi-Steel, Ernest Wheeler. Foundry Trade Jl., vol. 23, no. 233, Feb. 3, 1921, pp. 99–100. Als. Eng. & Indus. Management, vol. 5, no. 8, Feb. 24, 1921, pp. 234–236. Tables are given showing results of tensile, physical, chemical and foundry tests of semi-steel and ordinary cylinder iron.

Tests. What is Semi-Steel? H. Field. Foundry Trade Jl., vol. 23, no. 237, Mar. 3, 1921, pp. 201–204. Records of chemical and physical tests. Paper read before Birmingham Branch, Instn. British Foundrymen.

SHEARS

Large High-Speed. Six-Foot High-Speed Shearing Machine. Engineering, vol. 111, no. 2880, Mar. 11, 1921, pp. 286–288, 7 figs. Driven by electric motor carried on bracket bolted to side frame, through cut gearing and treadle running whole length of front of machine.

SHIP PROPULSION

Hydraulic. The Hydraulic Propulsion of Ships.

ENGINEERING INDEX (Continued)

Torsion Strain Meter. A New Torsion Strain Meter, E. H. Lamb. Engineering, vol. 111, no. 2880, Mar. 11, 1921, pp. 279–280, 7 figs. Each of ends of bars is attached to one of two brass tubes which slide freely one within the other. Slide twist of bar is measured by determination of relative motions of two plain mirrors, each fixed on one of brass tubes.

THERMIT WELDING

Wrought-Iron Pipe. An Unusual Case of Thermit Pipe Welding, Edward A. Miller. Power, vol. 53, no. 9, Mar. 1, 1921, pp. 351–352, 8 figs. Experience in welding wrought-iron pipe.

TIDAL POWER

Severn Barrage Scheme. Severn Barrage Scheme. Engr., vol. 131, nos. 3400–3401, Feb. 25 and Mar. 4, 1921, pp. 210–211 and 230–231. Account of joint meeting held by Instns. of Civil Engrs., Elec. Engrs. and Mech. Engrs. to discuss Severn barrage scheme for utilization of tidal power on Severn, and particularly third interim report of Water Power Resources Committee of making a plan for utilization of such power by means of a dam across estuary and a high-level reservoir a certain distance up the river.

TIMEKEEPING

Time Clocks. Time Measurement and Control (Zeitmessungen und Zeitkontrollen), Ed. Michel. Betrieb, vol. 3, no. 8, Jan. 25, 1921, pp. 59–62, 6 figs. Description of time clocks with special reference to the calculagraph clock. Report of the Assn. German Works Engrs.

TIME STUDY

Group of Machines. How to Make Group Time Studies, Philip Bernstein. Indus. Management, vol. 61, no. 5, Mar. 1, 1921, pp. 187–189, 4 figs. Method of setting rates when a number of machines are operated by one man.

TIRES, RUBBER

Substitutes. Substitutes for Rubber Tires, H. Jahr. India Rubber World, vol. 63, no. 6, Mar. 1, 1921, pp. 417–421, 42 figs. In writer's belief, solids or semi-solids made of an infinite variety of compounds may be successfully used. Notes on fiber, cord, felt, hair, paper and cardboard, and asphalt tires. Translated from "Kunststoffe."

TOLERANCES

Determining. Tolerances in Mechanical Construction (Les "tolérances" dans la construction mécanique), C. Reinewald. Génie Civil, vol. 78, no. 6, Feb. 5, 1921, pp. 130–132, 7 figs. System of determining manufacturing tolerances.

TRACTOR ENGINES

Drilling Operations. Methods in a Tractor Engine Plant. Machy. (N. Y.), vol. 27, no. 6, Feb. 1921, pp. 516–518, 4 figs. Battery of drilling machines arranged for continuous operation.

Manufacture. Methods in a Tractor Engine Plant. Machy. (Lond.), vol. 17, no. 440, Mar. 3, 1921, pp. 665–668, 8 figs. Machining cylinder liners on rotary type of boring machine.

TRACTORS

Columbus Show. Parts and Accessories at the National Tractor Show, P. M. Heldt. Automotive Industries, vol. 44, no. 9, Mar. 3, 1921, pp. 497–500, 12 figs. Attention is called to air cleaners, traction devices for wheels tractors and automatic hitches, and also to rubber-tired wheels for road work, line-control mechanisms and drawbar pull indicator.

The Hydraucone Regainer, Its Development and Applications in Hydroelectric Plants

By W. M. White,[1] Milwaukee, Wis.

Those familiar with hydroelectric power-house operation where curved draft tubes are employed cannot have failed to notice the boiling and disturbance of the water at the outlet from curved tubes, which disturbance is clearly an evidence of inefficiency and loss of energy. The device described in this paper—the hydraucone regainer—provides a means for efficiently recovering the energy discharged from the runner for useful effect on the water wheel within the limited space available in the power-house foundations.

This new method of regaining pressure from velocity of fluids in motion consists in causing the stream flow to impinge upon some definite shape, either flat, conical or concave, thus changing its direction, and then placing an envelope around this shape so formed upon the particular base used, which envelope conforms to the shape of the fluid at entrance and gradually recedes from what would be the normal or free shape of the non-enclosed fluid upon the particular base used; the effect of this gradually diverging envelope being to change the velocity head of a fluid flowing at high velocity into its entrance into pressure and low velocity at its exit.

The field of application of the hydraucone regainer, according to the author, will be greater on low-head plants, although it is now being installed in connection with two 40,000-hp. units which are to operate under a head of 421 ft. Hydraucone regainers are now in operation or in course of construction in a number of plants to operate under heads varying from 8 ft. to 421 ft. and with water wheels developing from 150 to 40,000 hp.

The paper gives very complete particulars of the long series of experiments resulting in the development of the hydraucone regainer, as well as data of a series of tests made at the Holyoke Testing Flume, showing the increase in power-plant efficiency obtained by its use.

"HYDRAUCONE" is a new word coined for convenience in referring to the new method of transforming velocity head of fluids in motion into pressure head. This method consists in causing the stream flow to impinge upon some definite shape, either flat, conical or concave, thus changing its direction, and then placing an envelope around the shape so formed upon the particular base used, which envelope conforms to the shape of the fluid at entrance and gradually recedes from what would be the normal or free shape of the non-enclosed fluid impinging upon the particular base used; the effect of this gradually diverging envelope being to change the velocity head of a fluid flowing at high velocity into its entrance into pressure and low velocity at its exit. The angle of divergence of the envelope from the normal or free shape of the impinging fluid is such as to bring about the same phenomena of flow conditions as result in an expanding straight-axis tube such as the discharge end of a venturi meter. The new method therefore provides a means for transforming velocity head into pressure head within a short distance measured along the axis of the inflowing stream, and has useful application in water-power plants, supplanting the usual curved draft tube and providing for higher efficiencies with a minimum of excavation. For clearness reference is made in this discussion only to the single-Francis-runner vertical water wheel unless otherwise stated.

[1] Manager and Chief Engineer Hydraulic Department, Allis-Chalmers Mfg. Co.

Abstract of a paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper may be obtained on application. All papers are subject to revision.

The draft tube of a water wheel serves two purposes. The first of these is to maintain at the discharge side of the runner passages a suction action equivalent to the difference in elevation between the runner and the level of the tail water, thereby providing for the use of the total head. The second purpose is to transform the velocity head in the water as it is discharged from the runner into pressure head by the time the water reaches the end of the draft tube, and thus maintain at the discharge side of the runner passages a suction action greater than that which would be caused by the difference in elevation between the runner and the level of the tail water.

At first thought it seems like attempting to lift oneself with

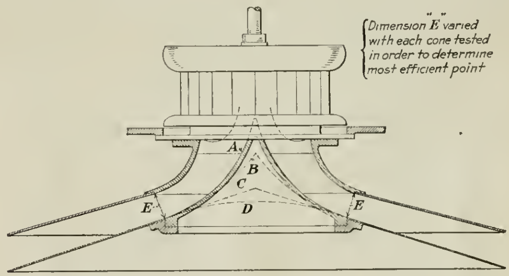

Fig. 1 Hydraucone Regainers with Cone Centers and Conical Plates

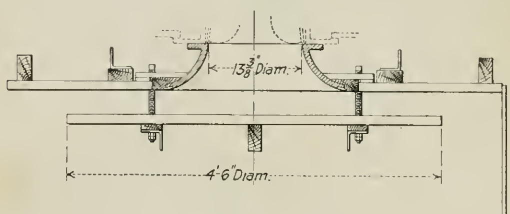

Fig. 2 Hydraucone Regainer with Flat Plate

one's bootstraps to endeavor to utilize the energy in water after it has left the water-wheel runner, but this utilization may be effected by an efficient transformation of the velocity head in the water discharged from the runner into pressure head, which causes an increased suction action at the runner and thus maintains a greater head acting on the runner than the total head as measured between the equivalent water level of the water at entrance to the water wheel and the level of the water in the tail race.

The necessity for an efficient means for regaining pressure from velocity of the water discharged from the water-wheel runner in modern power plants has been brought about by the ever-increasing demand for higher speeds of water wheels for given conditions of power and head. The cost of electric generators of such sizes and speeds as are usually employed in water-power plants varies inversely as the speed, hence the buyer maintains a constant urge for higher water-wheel speeds, to meet which many high-speed types of runners have been brought out. As the specific speed of a

runner increases, the percentage of energy it discharges also increases. A runner of moderate specific speed discharges water with such velocity that the energy contained in the water as velocity head is about 10 per cent of the energy of the total head; and runners of highest specific speeds discharge the water at such velocity that the energy contained in it as velocity head is from 20 per cent to 25 per cent of the energy due to the total head acting on the water wheel. In order to secure high efficiency with high-speed runners it is therefore vital to regain the major portion

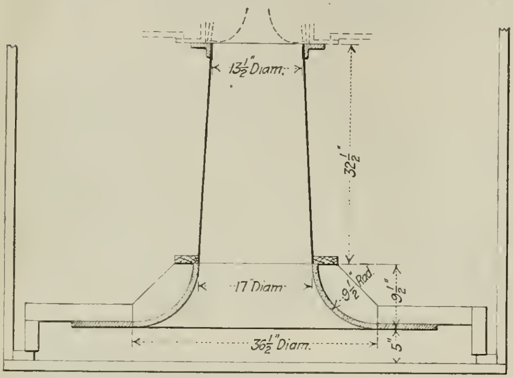

Fig. 3 Combination of Straight Draft Tube and Hydraucone Regainer with Flat Plate

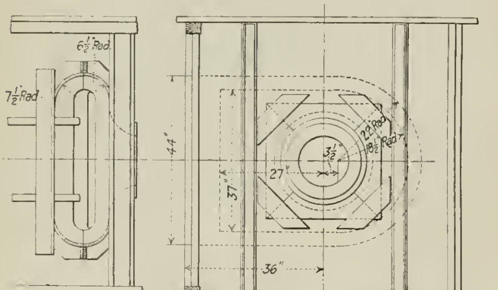

Fig. 4 Dimensions of Model of Hydraucone Regainer Used in a Number of Power Plants

of the energy contained in the water discharged from the runner for useful effect upon the water wheel, for as more of the energy which is discharged from the runner is regained, the efficiency of the water-power plant is increased.

A good illustration of the necessity for a better means of regaining the energy discharged from water-wheel runners is afforded by the installation at the Aluminum Company of America's plant at Massena, New York, where five 6000-hp. vertical two-runner water-wheel units are installed. Efficiency was of great importance, and the contract was placed with the manufacturer upon a bonus and penalty basis for efficiency, this being $6000 for each per cent of efficiency per unit. The contract value of 1 per cent increase in efficiency in this development was therefore $30,000. Very elaborate tests were conducted by the Aluminum Company of America to determine the efficiency of these water wheels, the final results of which showed that the guaranteed efficiency was exceeded by about 2 per cent, yet the efficiency could have been increased very much more had a better form of draft tube been installed.

Experimental Work Resulting in the Development of the Hydraucone Regainer

The necessity for a more efficient means of regaining pressure from velocity and changing the direction of flow from the water wheel within the limited space available in power-house foundations led the writer to undertake a long series of experiments resulting in the development of the hydraucone regainer as set forth in the following pages.

A hydraulic laboratory was installed in a garage near the corner of Second and Wright Streets, Milwaukee, the essential equipment of which was as follows:

A water box 6 ft. wide, 5 ft. 6 in. high, and 32 ft. long
A centrifugal pump of 14 in. discharge diameter, belt-driven by a 25-hp. motor which served to supply a maximum of 14 cu. ft. per sec. of water against a maximum head of about 15 ft.
A supply pipe leading from the centrifugal pump to a 42-in. diameter cylindrical plate-steel water-wheel casing with side inlet
A water wheel equipped with wicket guide vanes
A high-speed runner, being a 9-in. model of type No. 13, Allis-Chalmers Mfg. Co. The discharge diameter of the runner where it joins the draft tube is 13$^3/_8$ in. Specific speed, 90 (English system)
Also a prony brake, a tachometer, various pitot tubes, gages and manometers, etc.

The output of the water wheel under good testing conditions was about 8 hp., so that the size of the equipment was sufficient to give a practical demonstration of the relative efficiencies of the draft tubes, hydraucone regainers and other devices tested.

A great many tests were made with many objects in view, and comprised tests with no draft tube; tests of straight conical and short curved draft tubes; Argo and Mio curved draft tubes; hydraucone regainers with cone centers, with conical plates, and with flat plates; a combination of straight draft tube and hydraucone regainer with flat plate; and a power-house model of a hydraucone regainer.

The hydraucone regainers with cone centers are shown at *A* and *B* in Fig. 1, and the hydraucone regainer with conical plates at *C* of the same figure. The hydraucone regainer with flat plate is shown in Fig. 2.

Fig. 3 shows a combination of a straight draft tube with a hydraucone regainer having flat plates. This type, now frequently employed, was the one installed at Niagara Falls, as will be more fully described later. Fig. 4 gives the dimensions of a model of hydraucone regainer such as has been installed in several power plants now in operation.

Figs. 5 and 6 show respectively the test curves plotted from the results of data obtained in the tests of the models of the Argo draft tube No. 1 and the hydraucone regainer with flat plate. It will be noted that the test results were all reduced to a basis of 1 ft. head before the results were plotted. Examination of these curves should convince any one that the tests must have been carefully conducted, and that the results may be relied upon to give at least a fair comparison of the relative efficiencies of the various devices tested. The identical water wheel, equipment, and setting were used in all these tests.

Fig. 7 shows a series of efficiency curves plotted between horsepower and efficiency from test curves similar to those illustrated in Figs. 5 and 6. These curves give the efficiencies obtained at constant speed of the turbine throughout the range of the curves. The speed at 1 ft. head is indicated in the figure by the abbreviation r.p.m.$_1$. The speed at best efficiency is different for each curve.

It will be noted that the more efficient the regaining device, the higher the speed as well as the higher the power of the water wheel. It will further be noted that the increase of efficiency from "no draft tube" as shown in curve 1 to "hydraucone regainer" as

shown in curve 5 is from 77½ per cent to 86 per cent, with an increase in speed from r.p.m.$_1$ = 155 to r.p.m.$_1$ = 165, and with a maximum power from hp.$_1$ = 0.270 to hp.$_1$ = 0.310. The great gain, therefore, by the use of hydraucone regainers is not only in higher efficiency but is also in both speed and power.

Curve 1, Fig. 8, shows the efficiency of the short curved draft tube, which, it will be noted, is less than with no draft tube at all. There is no question but what many plants in operation today are losing power because of the poor curved tubes they use.

Curve 5, Fig. 8, shows the efficiency of the power-house model of hydraucone regainer whose dimensions are given in Fig. 4 and are approximately the same as those of the hydraucone regainer installed at the Hiram plant of the Cumberland County Power & Light Company, Portland, Maine.

Curve 4 gives the results of a test of a plate-steel curved draft tube that are very creditable, but it is very rare that there can be installed in a power house a draft tube of the same relative dimensions as those of the model employed, for the cost of excavation would be prohibitive.

Fig. 9 gives the results of tests with the hydraucone regainers shown in Fig. 1 and also with the straight tube and hydraucone regainer illustrated in Fig. 3. These curves are plotted from elaborate tests similar to those of Figs. 5 and 6 and show clearly that the hydraucone regainers with flat plates are slightly more efficient when tested with the model turbine than those with cone centers.

Fig. 10 presents the results of tests made on various shapes of conoidal chambers, from which it will be seen that the hydraucone regainer as here discussed is susceptible of a reasonable variation without materially affecting its efficiency.

The early tests at the laboratory were made to determine the effects on the model water wheel of radial passages extending outward but with a slight angle downward from the horizontal, and with passages leading directly from the runner. These early tests were not so successful as the later tests because it was not then realized that in order to change the direction of the water from axial as it flowed from the runner to radial and outward, it was necessary to take into consideration and provide for what was afterward called the "hydraucone action" of water, which requires a definite curvature to properly change the direction of the water from axial to radial if the greatest regain of velocity head is to be expected and consequent losses are to be avoided. In searching for a means for increasing the efficiency of regain the author recalled some experimental work done in connection with the determination of the pitot-tube formula in 1900, the results of which were published in Vol. 22 of the Journal of the Association of Engineering Societies (1901), page 284. Fig. 21 of that publication shows the stream lines and velocities of a jet impinging upon a plate, and by reason of the importance of the principle there disclosed in the new method of regaining pressure from velocity, it is reproduced here as Fig. 11.

The lines in this figure represent the stream lines of flow of the water, which were traced by injecting a small stream of blue water into the jet at various points along a diameter and noting and recording the flow line. The plate employed in this case was made of glass in order to afford ample light for making the observations. The figures given in the circles represent the velocities in feet per second at the various locations indicated. It will be noted that the water at the center of the jet slows up as it reaches the plate and delivers its velocity head into pressure head at the center of the plate. This pressure head at the center is transformed into velocity as

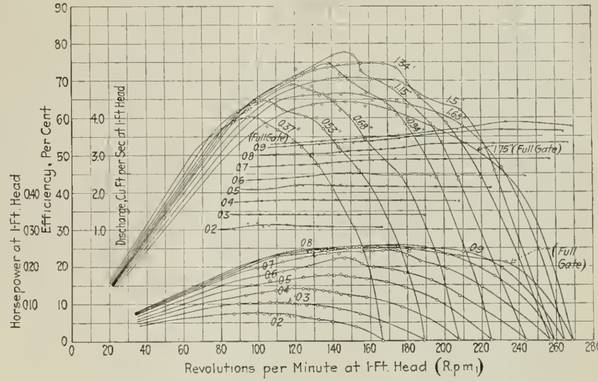

Fig. 5 Curves of Test of Model of Argo Curvrd Draft Tube No. 1

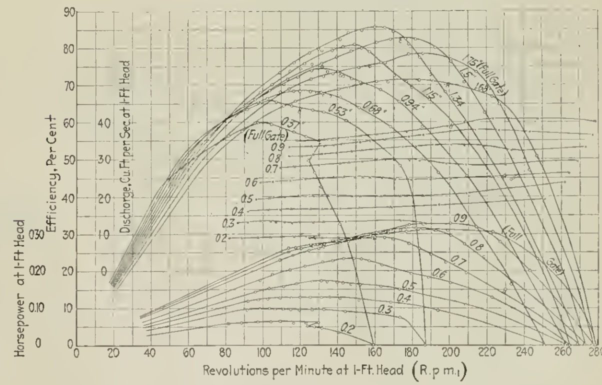

Fig. 6 Curves of Test of Model of Hydraucone Regainer with Flat Plate

(7½-in.-radius conoidal chamber, 4 ft. 6 in. in diameter)

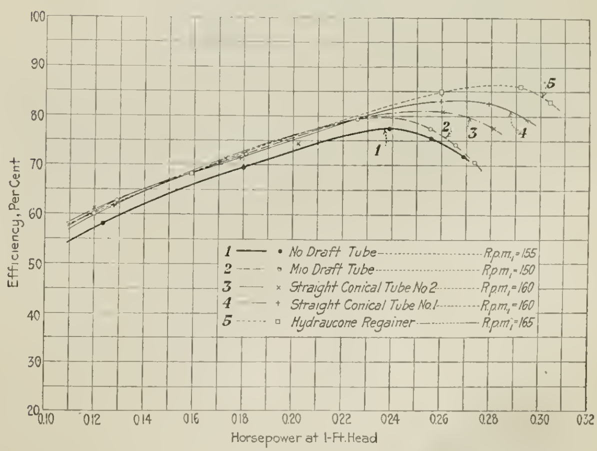

Fig. 7 Curves Showing Relation Between Efficiency and Horsepower at 1 Ft. Head

this stream flow passes from the center of the point of impingement to the point beyond the radius of curvature. Referring to

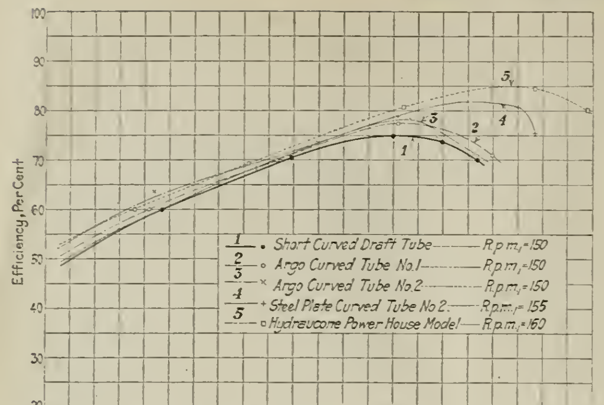

Fig. 8 Curves Showing Relation Between Efficiency and Horsepower at 1 Ft. Head

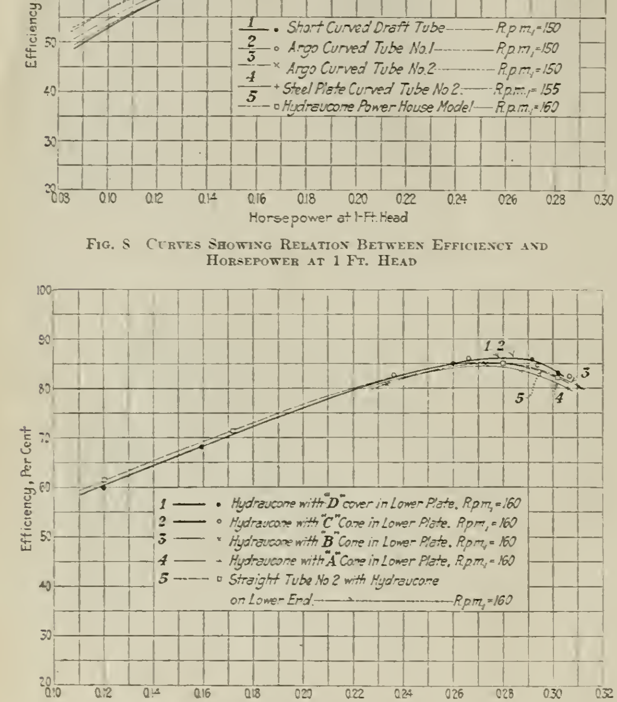

Fig. 9 Curves Showing Relation Between Efficiency and Horsepower at 1 Ft. Head

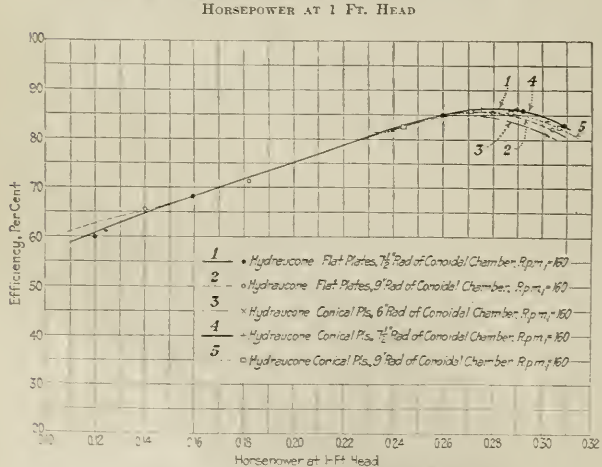

Fig. 10 Curves Showing Relation Bewteen Efficiency and Horsepower at 1 Ft. Head

Fig. 11, the radius of curvature of the water in making its change in direction is a definite curve and is the minimum which can be used in regaining devices and yet obtain the reactions within the point of impingement which will give smooth stream flow of discharge along the plate and consequently without eddies and attendant losses.

By the term "hydraucone action" of water is meant that action which occurs when an unenclosed stream impinges against and is deflected along a surface. Fig. 11 illustrates the hydraucone action of water when a jet impinges normally upon a flat plate. In considering the three outer stream filaments it was noted and recorded in 1900 that the cross-sectional area of the flow increased in making the turn and decreased at the exit from the turn. By placing a cone on the plate with its axis in line with the center line of the jet the outer shape of the curvature of the water is changed, but not to a great extent because of the low velocities within the center portion of the impinging jet.

When the hydraucone action of the water as illustrated in Fig. 11 was taken into consideration in the laboratory work, conoidal chambers were designed such as the one shown in Fig. 2, and when these were combined with the radial passages the desired results were immediately secured.

Tests of Smaller Models

The tests of the various model draft tubes and hydraucone regainers made at the laboratory with the small turbine illustrate the practical, economical and efficient application of the hydraucone principle for increasing the efficiency of water-power developments. Coincident with the series of tests in connection with the small turbine, a series of tests on smaller models were made without the use of a model water wheel. Sometimes these small models were tested before the large models were built and tested with the turbine, and sometimes afterward. These models were all made of such size that the entrance was 4 in. in diameter at the throat as compared with $13^3/_8$ in. at the throat of the larger models.

The apparatus used for testing the small models is shown in Fig. 12. The model water wheel was removed from the plate-steel cylindrical casing and in its place the curved wooden section *L* was bolted to the opening at the bottom of the casing. At the bottom of the curved piece *L* was connected a 4-in. diameter throat *T*, made of brass pipe with flanges, to the lower end of which the various small models were fastened. Four piezometer openings and as many gages were provided to indicate accurately the pressure at the throat. Gages *a*, *b* and *c* serve to illustrate more or less diagrammatically the method of computing the efficiencies of the small models. The difference in elevation between gages *a* and *c* was kept about the same. The reading of the throat gage *b* varied widely, depending upon the efficiency of the regainer device used. The efficiency of these small models was taken as *B* divided by *A*, or in other words, the velocity head regained divided by total velocity head in the water as it passed through the throat *T*. A small model hydraucone with large-diameter plate is shown attached to the throat in Fig. 12. The model hydraucone was detachable from the flange *F* of the throat, to which were bolted the various devices tested.

Tests were made with the hydraucone regainers having cones in the center of the chamber, and the distance between the plates was varied. With a tall cone in the center similar to *A*, Fig. 1, the efficiency obtained was less than 70 per cent. By substituting a low cone similar to that represented by *B* in the same figure, the

maximum efficiency by varying the distance between the plates was found to be 70 per cent.

One series of tests copied from the record book of a model hydraucone as shown in Fig. 12 having a $2^3/_4$-in. radius of curvature of the conoidal chamber, gave the following efficiencies as the distance between the plates was varied:

Distance between plates, in...	$\frac{1}{2}$	$\frac{17}{32}$	$\frac{9}{16}$	$\frac{19}{32}$	$\frac{5}{8}$	$\frac{3}{4}$	$\frac{7}{8}$
Efficiency, per cent...........	76.7	77	78.5	78.7	78	74	68

By cutting down the diameter of the upper and lower plates to 18 in., using the same radius of curvature of the conoidal chamber, namely, $2^3/_4$ in., and varying the distance between the plates, the following efficiencies were obtained:

Distance between plates, in........	$\frac{1}{2}$	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{7}{8}$
Efficiency, per cent................	61	65.5	67.5	67	68.8	59.3

Conoidal chambers of various radii of curvature were tested with cone centers, flat plates, and then with depressions or con-

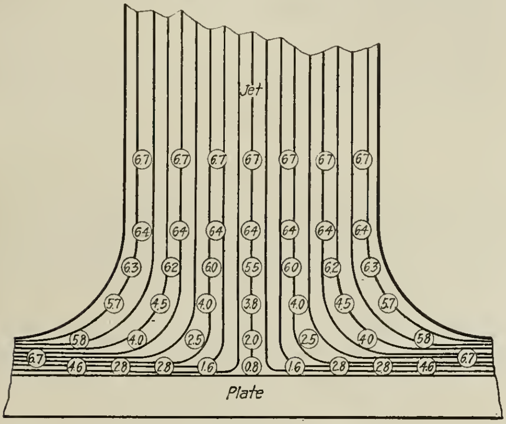

Fig. 11 Hydraucone Action of Water When a Jet Impinges Normally on a Flat Plate

cave surfaces, the latter being developed to secure shorter radius of curvature of the conoidal chamber. The efficiencies obtained with the concave surfaces were about equal to that obtained by the use of the flat plate when the proper curve of the conoidal chamber was used.

Tests were also made upon straight conical and curved draft tubes, and upon square expanding nozzles and elliptical-shaped nozzles as contrasted to the circular straight nozzles. Rectangular and conoidal bends were also tried out.

Holyoke Tests

At the completion of the tests of the various regainers and model draft tubes at the laboratory, a series of tests were made at the Holyoke Testing Flume on a large water wheel having a runner of 30 in. nominal diameter and a discharge diameter of 38 in. The objects of these tests were to verify the results already obtained at the laboratory, and to obtain records of the performance of the hydraucone regainer which could be presented to the engineering profession with the assurance that they were reliable, and could be used for comparison with the results obtained with other forms of draft tubes tested at Holyoke. The water wheel was first tested with a straight draft tube 8 ft. $3^1/_8$ in. in length and with diameters of 3 ft. $3^1/_2$ in. and 6 ft. 3 in. at the smaller and larger ends, respectively. This was the best tube of this type developed by the Allis-Chalmers Manufacturing Company for testing purposes. The results of the tests are shown in Fig. 13, Holyoke test No. 2445, dated Mar. 3, 1916.

The next test was made by placing the water wheel

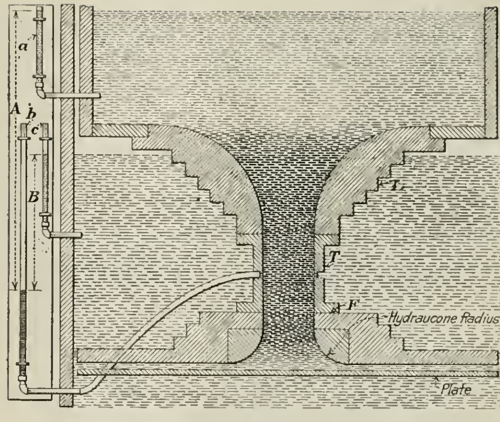

Fig. 12 Apparatus Used in Testing Small Model Draft Tubes and Hydraucone Regainers

directly on the hydraucone regainer as shown in Fig. 14, and the results are given in Fig. 15, Holyoke test No. 2460, dated May 5, 1916. Fig. 16 gives the results of a test of the water wheel when set on a short straight conical draft tube (3 ft. long), with the discharge of the tube connected with the hydraucone regainer. (Holyoke test No. 2461, dated May 16, 1916.)

Two shapes of conoidal chambers were made and tested; one of which is illustrated in Fig. 14. Tests were made with the plates of the hydraucone regainer set at various distances apart. These tests confirmed those made at the laboratory and showed that the hydraucone regainer could be relied upon for giving high efficiency with commercial water wheels under actual operating conditions. A maximum efficiency of 91.6 per cent was obtained with the use of the hydraucone regainer as shown by Holyoke test No. 2461, which was slightly greater than that obtained with the long straight draft tube in Holyoke test No. 2445. The test

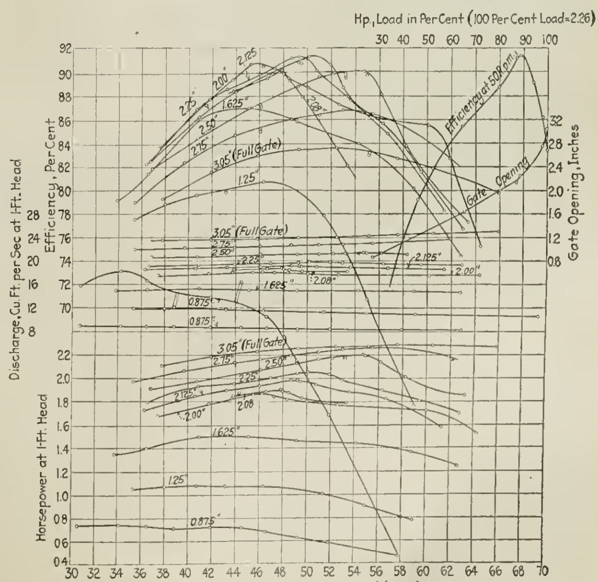

Fig. 13 Holyoke Test No. 2445 of 30-in. Runner with Long Straight Conical Draft Tube
(20 guide vanes; guide case $14^1/_4$ in. wide.)

of the water wheel with the hydraucone regainer showed better characteristics at speeds both below and above normal than the test with the straight draft tube, all of which might be expected in view of the radial passages of the hydraucone regainer in which

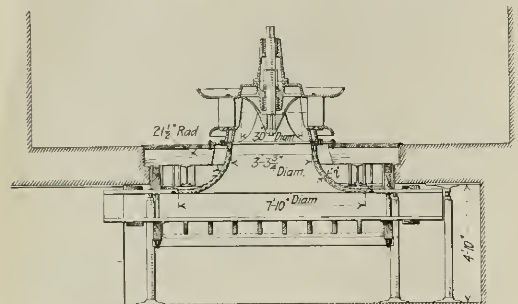

Fig. 14 Water Wheel Placed Directly on Hydraucone Regainer as in Holyoke Test No. 2460

the whirling action of the water is utilized for increasing the efficiency.

Hydraucone regainers with cone centers such as *A*, Fig. 1, were not tested at Holyoke because the laboratory experiments showed conclusively that hydraucone regainers with flat plates gave better efficiency. The friction of the water along the surface of a hard cone center is much greater than the internal friction when the water forms its own cone as shown in Fig. 11. This is one reason why the hydraucone regainer with flat plate gives better efficiency than the hydraucone regainer with cone center.

Results Obtainable by Using Hydraucone Regainers with Runners of Different Specific Speeds

The hydraucone regainer may be employed in any power plant operating under any head with a resulting increase in efficiency. Its actual value in power plants operating under different heads with runners of different specific speed may be seen from Table 1.

Runner No. 1 is a type identical with that used on one of the 37,500-hp. turbines recently put into operation in Station No. 3 Extension of the Niagara Falls Power Company. The specific speed of this runner is about 40 (English system). Runner No. 2 is a reasonably high-speed runner for low-head plants, such as that installed at the Argo Plant of the Eastern Michigan Power Company, and it is the same type as that used in the experiments made at the laboratory. Runner No. 3 is the Allis-Chalmers No. 404 high-speed type furnished to the Cheboygan Electric Light & Power Company, Cheboygan, Mich. This runner was described by Mr. Nagler in his paper presented at the 1919 Annual Meeting of the Society.[1] The axial component of the velocity of the water discharging from each runner is shown in column 6. The energy discharged from the runner in each case is shown to be respectively 4 per cent, 13.7 per cent, 22.4 per cent of the energy of the total head. Draft tubes on high-head plants are usually much more efficient than those on low-head plants. A draft-tube efficiency of 40 per cent may be obtained under ideal conditions in a suitable curved draft tube for use in connection with runner No. 1, but draft tubes on low-head plants are not so efficient, and the efficiency of a curved draft tube such as would be used with runner No. 2 would be about 20 per cent, and with runner No. 3 certainly not exceeding 20 per cent.

[1] A New Type of Hydraulic-Turbine Runner, Forrest Nagler, Trans. Am.Soc.M.E., vol. 41, p. 829.

Table 1 Increase in Power-Plant Efficiency Resulting from Use of Hydraucone Regainer

1 No. of runner	2 Specific Speed	3 Nominal diameter of the runner, in.	4 Discharge diameter of the runner, in.	5 Cu. ft. per. sec. discharged at 1 ft. head	6 Vertical component of water discharged from the runner	7 Energy in discharged water, per cent	8 Assumed efficiency of draft tube, per cent	9 Loss of energy with draft tube, per cent	10 Assumed efficiency of hydraucone regainer, per cent	11 Loss of energy by hydraucone, per cent	12 Increase of efficiency by use of hydraucone, per cent
1	40	30	28	1.97	1.65	4	40	2.40	70	1.2	1.2
2	90	30	44.5	32.05	2.97	13.7	20	11	70	4.1	6.9
3	160	30	30	18.5	3.8	22.4	20	17.9	70	6.7	11.2

The efficiency of the hydraucone regainer for use with each of the three runners would be at least 70 per cent. The greater efficiency of the hydraucone regainer over the curved draft tube results in increasing the power-plant efficiency by 1.2 per cent, 6.9 per cent, and 11.2 per cent, respectively, for runners Nos. 1, 2 and 3, as shown by column 12 of Table 1. From this it will be

Recording Ash-Pit Loss From Chain-Grate Stokers

By E. G. Bailey,[1] Cleveland, Ohio

This paper presents certain preliminary data obtained from a device recently developed to record the ash-pit loss from chain-grate stokers and thus enable the fireman to effectively control this factor.

The device consists of a thermometer bulb filled with nitrogen and connected through a capillary tube to a recorder consisting of a mercury U-tube, one leg of which is open to the atmosphere and carries a float to which the recorder pen is attached. It has been found that when this bulb is properly located near the rear of a chain-grate stoker, its temperature will respond definitely to changes in the amount of combustible going to the ash pit and will vary in direct proportion to the heat thus lost.

Records of ash-pit loss, excess air, unburned gas, flue-gas temperature and boiler rating make it possible to plot characteristic performance curves for stokers showing the losses due to unburned combustible, unburned gases and excess air, and to determine the proper amount of excess air to be maintained and also the most efficient capacity. These curves can be used to compare relative efficiencies of different types of stokers, the suitability of different kinds of coal, and the effectiveness of the control by the fireman.

There has been more guesswork and less knowledge regarding ash-pit loss than any other thing of equal importance in the boiler plant. It pays to watch the ash pile from every kind of stoker or even hand-fired furnaces, though it be only visual inspection to note whether it is well burned out or full of combustible. To sample and analyze the ashes regularly and calculate the heat lost in that manner is better still, yet it is done in comparatively few plants and falls far short of accomplishing the desired result. A sample taken from the entire plant each day leaves the responsibility divided between the different firemen and different types of stokers. To take a sample from each boiler for each shift would still not accomplish as good results as if the ash-pit loss were continuously recorded for each boiler.

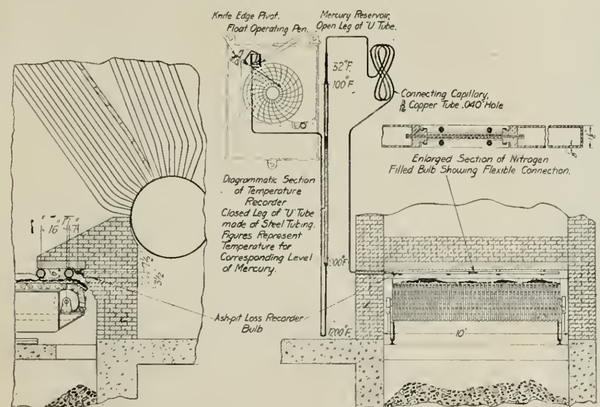

Fig. 1 Ash-Pit Loss-Recorder Installation on Natural-Draft Chain-Grate Stoker in Station B

Instantaneous readings of any kind are most valuable in aiding the fireman to obtain results. He can then see a faulty condition as soon as it takes place or even starts to take place, and remedy it promptly. If such readings are recorded continuously the fireman can see how quickly the remedy is effective. Such records also show the executive in charge of the plant just what took place at all times.

It is the purpose of this paper to present some preliminary data obtained from a device recently developed to record the ash-pit loss from chain-grate stokers. It may later be extended to some other types of stokers of either the present or modified design, but the great need for it on chain grates led to its being applied to these first.

Method of Recording Ash-Pit Loss

The fundamental principle used in recording the ash-pit lost by this method is to place a temperature-recorder bulb at a point

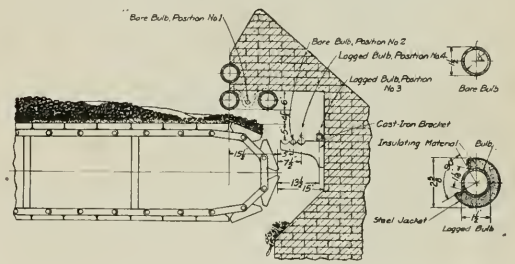

Fig. 2 Ash-Pit Loss Recorder on Forced-Draft Chain-Grate Stoker in Station A, Showing Different Bulb Constructions and Locations

near where the ashes are discharged from the active section of the grate or furnace. The bulb is not in contact with the ashes but receives only the radiant heat from the coke being discharged. The relation between this temperature and the amount of combustible in the refuse, and the heat loss due to it, is established by taking a series of samples corresponding to different temperature readings.

If the ashes are well burned out, so that there are no live coals, the temperature is comparatively low. Even though the ash has clinkered rather badly and retained a certain amount of temperature, it has usually lost its glow and is comparatively cold from a radiation standpoint. The coke coming over is still ignited and at a temperature of about 1800 to 2000 deg. fahr., so that its radiant heat to the bulb is sufficient to cause very decided changes in the temperature readings.

In selecting a location for the temperature-recorder bulb, it is necessary to have it shielded from any radiant heat of the furnace itself, and also as free as possible from changes in temperature due to the surrounding brickwork, circulation of air, etc. It is further necessary that the bulb extend across the entire width of the grate and be so constructed as to obtain an accurate average in case the amount of coke coming over is greater on one portion of the grate than an other.

Fig. 1 shows an installation on a natural-draft chain-grate stoker with a 9-ft. bulb located just beyond the water back, which shields it from the heat of the furnace. It is located about seven inches above the rear end of the grate so that the radiant heat from any coke passing under it will increase its temperature.

The Temperature Recorder

The temperature-recorder bulb itself is made very rugged to withstand this service. It is constructed of $1^1/_2$-in. steel tubing with $^1/_8$-in. wall and all joints welded. The bulb is charged with

[1] President, Bailey Meter Co., Mem. Am.Soc.M.E.

Abstract of a paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Copies of the complete paper may be obtained on application. All papers are subject to revision.

nitrogen and the gas pressure that is exerted by an increase in temperature is conducted through a $^3/_{16}$-in. copper capillary tube to the recorder. The recorder consists of a simple mercury U-tube, one leg of which is open to the atmosphere and carries a float to which the recorder pen is attached.

The other leg of the U-tube is made up of sections having different cross-sectional areas so that the pen movement is suppressed below and above the range to be recorded on the chart. It is also possible, if necessary, to have the area of one leg of the U-tube variable so that the percentage of heat loss will be recorded directly with uniform gradations on the chart in case the relationship between the ash-pit loss and temperature should not be a straight line.

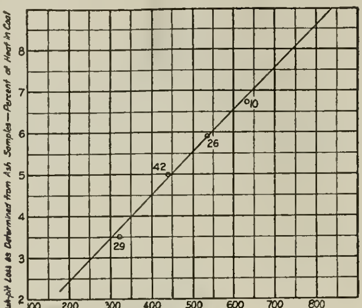

Fig. 3 Ash-Pit Loss and Temperature Relation for Bare Bulb in Position No. 2 (Fig. 2) on Forced-Draft Chain-Grate Stoker as Operated in Station A

(Figures represent number of individual tests averaged.)

The bulb can be made in sections short enough to be installed where the alley between two boilers is narrower than the width of the boiler itself. Each section, however, is welded permanently with $^1/_4$-in. No. 13 gage steel tube, making a flexible connection so that it can be folded up and then straightened out as it is installed in the furnace.

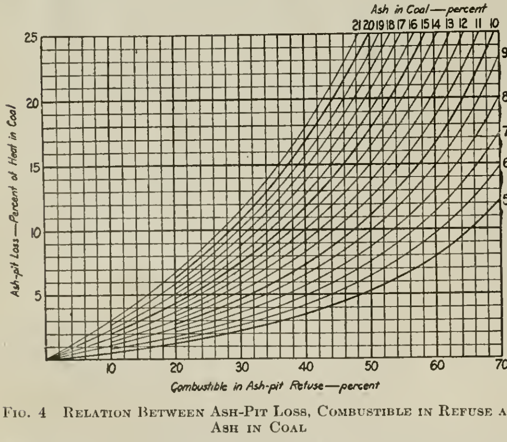

Fig. 4 Relation Between Ash-Pit Loss, Combustible in Refuse and Ash in Coal

Up to the present time the experiments have been largely confined to the selection of the best locations for the bulb with respect to the grate and also to determine the relative advantage of bare bulbs and those having lagging around a portion of their circumference so as to minimize the heat received from or given off to the surrounding walls, air, etc.

Fig. 2 shows the location of a bulb at the end of a forced-draft chain-grate stoker. A bare bulb was first located at position No. 1 with cast-iron supports. It was found that when the fuel was up to the bottom of the water back and there was a slight positive pressure in the furnace, a flame would envelop the bulb, sending the temperature up to more than 1500 deg. No data were obtained from this recorder in the No. 1 position.

The bare bulb was next placed on the cast-iron bracket in position No. 2, and after operating several days it was found to be satisfactory as to temperature range and continuous operation. A series of calibration tests was then started to learn what combustible losses corresponded to the different temperature readings.

Relation Between Temperature and Combustible Loss

Samples consisting of *all* the ash discharged from the stoker were taken hourly. The ash as it accumulated in the hopper was quenched immediately by means of a water spray. At the end of the hour the ash was dumped from the hopper, crushed, mixed and quartered by hand until it was reduced to about 20 lb. of 4-mesh size, and sent to the laboratory. The analyses show combustible on the dry basis.

The samples from Station A were collected from time to time between January 20 and March 2, 1921, at times when it was convenient to do the work. Usually five to eight samples were taken each day. In all, 107 samples were taken during 15 different days. About half of them were taken during certain stoker tests that were being made on this boiler and the remainder under everyday operating conditions.

No special effort was made to change operating conditions from normal except in the case of a few samples, when more combustible was run over than usual in order to get some high points to establish the upper part of the curve.

The essential results for the 107 samples taken are plotted in Fig. 3, where each small circle represents the average of all temperature readings grouped between 300 and 400, 400 and 500 deg. fahr., etc. It is noted that the ash-pit loss is about 3.5 per cent at 300 deg. and increases 1 per cent for each 100 deg. temperature rise.

It was first thought best to plot the results between temperature and percentage of combustible in the ashes, but it was found that the ash in the coal varied between 8.5 and 14 per cent. From the curves of Fig. 4 it is noted that with samples having 30 per cent combustible the heat loss is 3.9 per cent from the 8.5 per cent ash coal and 7 per cent from coal with 14 per cent ash, hence each test was figured on a basis of the heat loss due to unburned carbon, expressed in percentage of the heat in the coal.

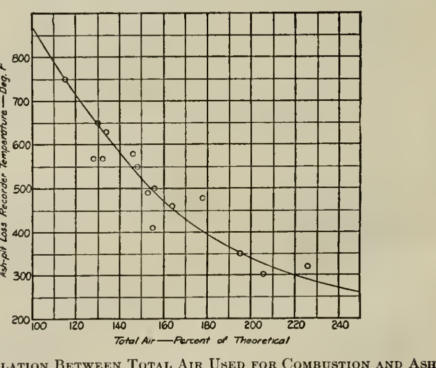

Fig. 5 Relation Between Total Air Used for Combustion and Ash-Pit Loss-Recorder Temperature Obtained from Forced-Draft Chain-Grate Stoker Operated in Station A

The relation between percentage of combustible in refuse, ash in coal, and ash-pit loss is given in the series of curves in Fig. 4. These curves are plotted from the formula:

$$\text{Combustible loss} = \frac{100\,ac}{(100-a)\,(100-c)}$$

where a is the percentage of ash in the coal and c the percentage of combustible in the refuse. This formula is based upon the assumption that all of the ash from the coal goes to the ash pit and

that the heating value per pound of combustible in the ash pit is the same as that of the combustible in the coal.

Emphasis is usually placed upon the percentage of combustible in the ashes as being the true measure of loss due to unburned carbon, but it is of equal importance to know the percentage of ash in the coal. There is more heat lost with 20 per cent combustible in the refuse from a coal with 20 per cent ash than with 40 per cent combustible in the refuse from a coal with 8 per cent ash.

One naturally questions whether the temperature of a bulb at such a location will vary with the percentage of heat lost or with the percentage of combustible in the refuse; whether either relation will hold true for different percentages of ash in the coal, or whether it varies with the boiler rating, grate speed, etc. The final answer to such questions can only be determined from results of actual tests. Fig. 3 is plotted from the 107 samples and it shows conclusively that the temperature varies directly with the percentage of the heat of the coal lost in unburned carbon. Various other plots and studies of the individual tests fail to show any tendency for the results to deviate from this curve due to changes in the percentage of ash in the coal, the grate speed, or the boiler rating.

This is very fortunate, as the temperature record can then be used directly in determining the heat loss without the necessity of bothering with percentage of ash in coal or any other modifying factors. In fact, the chart can be graduated direct in percentage of heat lost instead of temperature. Samples of coal and combustible are needed only for making the calibration tests, which

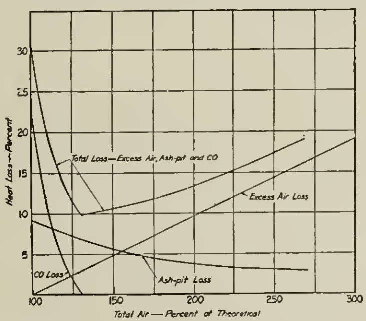

Fig. 6 Characteristic Loss Curves, on Basis of Total Air, of Forced-Draft Chain-Grate Stoker as Operated in Station A

should be determined for each type of installation. At least this will be necessary until more data have been obtained regarding location of bulb and the characteristics of different types of stokers, arrangements of water backs, etc., as these are likely to produce a different rate of temperature change as shown later in this paper.

Performance Results from Chain-Grate Stokers

It is well known that with a chain-grate stoker the ash-pit olss tends to increase as the excess air is decreased, and vice versa. It is only natural that more coal should be wasted over the end of the grate when the fuel bed is kept thicker and carried to the water back. When the fire burns short a reduction is made in the ash-pit loss, but there is a decided increase in the percentage of excess air. As a matter of fact this is generally true in all types of stokers, and even in hand firing. That is, a reduction in unburned coal usually means some increase in excess air, so that decreasing one loss increases another.

The problem is then to determine what method of operation will give the lowest total loss, and the ash-pit loss recorder makes it possible to plot out these relations as combustion characteristics of the stoker.

Relation Between Ash-Pit Loss and Total Air Used for Combustion

Fig. 5 shows a very definite relation between temperature as indicated by the ash-pit loss recorder and the total air used for combustion on a basis of the theoretical air being 100 per cent. In plotting the points the total air was taken from the ratio of air flow to steam flow as shown on chart records, using only periods when the steam flow, the air flow and the ash-pit loss-recorder temperature were each very uniform over stretches of two hours or more at one time, indicating that the conditions had settled to normal and were not varying continuously.

The values taken from the average curve of Fig. 5 are used to calculate the heat losses and are plotted in Fig. 6, showing the

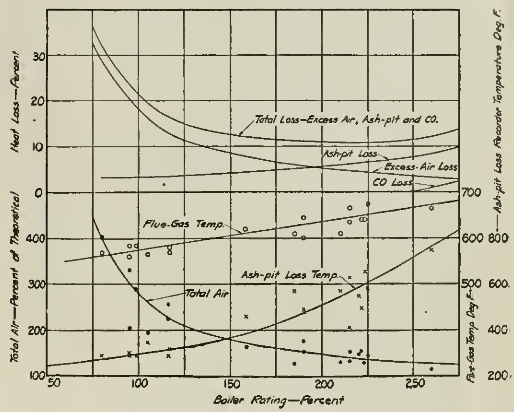

Fig. 7 Characteristic Loss Curves, on Basis of Boiler Rating, of Forced-Draft Chain-Grate Stoker as Operated in Station A

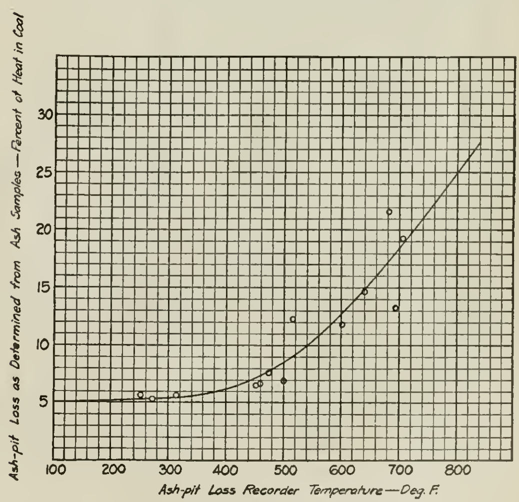

Fig. 8 Ash-Pit Loss and Temperature Relation, Bulb as in Fig. 1, on Natural-Draft Chain-Grate Stoker, Station B

(Each point represents an individual one-hour sample.)

characteristic loss curves for a forced-draft chain-grate stoker as operated in Station A. This set of curves shows that percentage of heat lost in excess of air (based on a 500-deg. temperature rise) increases from zero up to 19 per cent at 300 per cent total air. As the excess-air loss is reduced the ash-pit loss increases, but the rate of increase is less than the rate of decrease in the excess-air loss, so the total of these losses decreases until the total air is about 130 per cent. At this point CO and unburned gases appear, and the percentage of heat lost in consequence increases very rapidly as the amount of air is reduced to 100 per cent or the theoretical amount. It is therefore best to operate this stoker at about 130 to 140 per cent total air.

It is quite possible that, with a little better care upon the part of the fireman, the combustible loss could be considerably reduced on this type of stoker, even at this low percentage of excess air. This would then lower the total curves so that the combined loss would be still lower than the 10 per cent shown in Fig. 6 as the minimum point.

Relation Between Capacity and Stoker Losses

Fig. 7 shows the relations between the boiler rating and flue-gas temperature, excess air, unburned combustible, and CO, with the percentage of heat lost in each. The total of these three losses is seen to be at a minimum of 11 per cent at 225 per cent rating and to remain below 12 per cent at all ratings between 160 and 260 per cent.

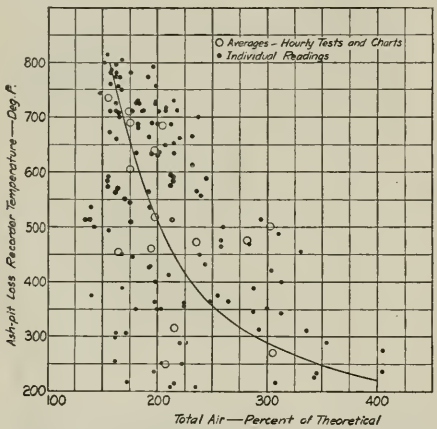

Fig. 9 Relation Between Total Air Used for Combustion and Ash-Pit Loss-Recorder Temperature Obtained from Natural-Draft Chain-Grate Stoker as Operated in Station B

The minimum loss in Fig. 6 is 10 per cent because the excess-air loss is calculated on the arbitrary bases of 500 deg. fahr. rise in flue-gas temperature, while in Fig. 7 it is calculated on the actual temperature, which is as high as 650 deg. at the higher rating.

If it were possible to operate this stoker with lower excess air at the lower ratings and lower ash-pit loss at the higher ratings, the total losses would be materially decreased and the curve would be flatter. In fact, the range of best efficiency as shown in Fig. 6 should be almost entirely independent of boiler rating if the same care is exercised by the fireman at the low ratings as he must exercise at the high ratings to produce the steam.

To obtain the total overall efficiency curves for stoker, furnace, boiler, and perhaps economizer, the other losses due to products of combustion and infiltration of air should be included according to the equipment used. There is also the question of overhead charges and repairs to stokers and brickwork that increase with higher rating or lower excess air.

Characteristic Curves of Stokers

This set of curves raises the question, can true characteristic curves be drawn showing the performance of the stoker itself? Very little has been done in this direction, but such data have been well established for centrifugal pumps, motors, turbines, fans and blowers.

In the operation of a stoker so much depends upon the character and quantity of coal being burned and also upon the human element of the fireman that the true characteristics of the stoker are usually so clouded that they do not appear in their true form.

Most boiler tests give combined efficiency of furnace and boiler as it is difficult to separate the two. In reality it is not necessary to separate these two efficiencies or even to determine the efficiencies at all, because a great deal more can be accomplished through studying the losses than can be obtained from knowing the overall efficiency alone. We know that if the losses are high the efficiency is low, and vice versa. It is also easy to separate certain of the losses and charge them directly to the furnace, while other losses may be chargeable entirely to the boiler and still others are beyond the control of either.

The three important losses existing in boiler and furnace operation that are chargeable directly to the stoker and furnace are unburned combustible in ashes, unburned gas, and excess air. The latter two losses may be influenced somewhat by the size of the furnace and combustion chamber, and the last one by the leakage of air through the boiler setting, but on the whole they depend almost entirely upon the stoker and its operation.

If the characteristics of the stoker are properly determined one can then see the best relation between these factors in order that the total of the three losses be a minimum. We are then assured the furnace efficiency is highest, even though we may not know the exact thermal efficiency of the furnace and stoker itself, separate from the boiler.

In operating stokers it has been considered that the character of the coal and the method of operation were far more important than the characteristics of the stoker itself. This, however, is only an admission that the stoker was not so designed that its characteristics would dominate over the other factors, namely, coal and fireman. Very great improvements have been made in stoker design and methods of operation, but there is need for still further advancement. A careful analysis of the problem by means of continuous graphic records of all the losses and characteristic performance curves like those shown in Figs. 6 and 7 will aid in further improvements in both design and operation as well as in selecting coal for the stoker or the selection of a stoker for the coal available.

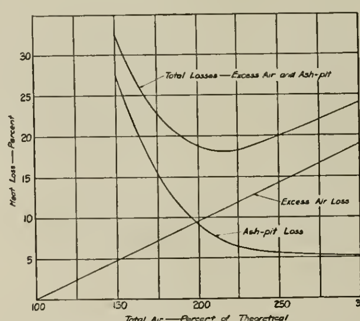

Fig. 10 Characteristic Loss Curves, on Basis of Total Air, of Natural-Draft Chain-Grate Stoker as Operated in Station B

Even where ash-pit loss recorders cannot now be easily applied to some types of stokers it is possible to take hourly samples of the refuse and plot the characteristic combustion and capacity curves like those in Figs. 6 and 7. For stokers with intermittent ash dumps the period for each test should be the same as the period between dumps, maintaining the operating conditions as uniform as possible during this period and taking the ash sample from each dump. As the value of these results does not depend upon coal weights and evaporation efficiencies, short tests are satisfactory for determining the losses due to excess air, unburned gas and unburned coal. All of the losses of the boiler heat balance, except radiation, can be determined almost if not quite as accurately as can be the evaporation.

Results from Natural-Draft Chain-Grate Stoker at Station B

Figs. 8 to 12 give the data from thirteen ash samples and tests on a natural-draft chain-grate stoker equipped with an ash-pit loss recorder as shown in Fig. 1. These data were obtained on three consecutive days from a boiler that was being operated in a stand-by station. The load conditions did not require careful attention to the stoker operation, hence the results should not be taken as indicative of the best performance with this type of

stoker. Neither should these results be used for comparing one type of stoker with another, because the operating factors, namely, coal and fireman, may be very different.

In Fig. 8 the ash-pit loss increases very slowly with the initial rise in temperature and then more rapidly at the higher temperatures. Referring to Fig. 1, it will be seen that the bulb is located at a different position with respect to the fuel bed than in Station A. In this case the bulb is directly over the end of the grate, and looks down upon the coke as it passes beneath it. With a very short fire the coke may "go out" or cease to burn before it reaches the water back and yet contain a considerable percentage of combustible, hence the minimum loss of 5 per cent with little or no radiant heat. As soon as a few pieces of hot coke are carried over, the effect upon the bulb is very marked and a considerable rise in temperature takes place until the grate is covered with coke. A greater amount of combustible will add only to the thickness of the layer and not increase the area of the hot coke within the vision of the bulb in this location. The increase in the temperature of the bulb is due only to the closer proximity of the hot coke to it after the grate is once covered.

In Fig. 9 the relation plotted between total air and ash-pit loss-recorder temperature shows widely scattered points. This is largely because the fuel-bed conditions vary rapidly, and there is considerable time lag between the condition of the fuel bed on the grate proper and the amount of coke being discharged at the same time. The log, Fig. 12, plotted over a short period, shows a typical case of the variations as the fire burns thin and is again thickened. The ash-pit loss-recorder temperature drops with the short fire, but the lowest temperature is not reached until twenty minutes after the greatest air excess and the lowest steam flow.

The conditions of the fuel bed on this stoker are sometimes very good and sometimes very poor, just as it may happen, due either to the stoker characteristics, the human factor, or the coal factor, or to a combination of all three. In any case there are certain average conditions which tend to repeat and show the relationship between the various factors. It is very evident from Fig. 9 that very high excess-air and high ash-pit losses do not occur at the same time, although either may be low when the other is high, but they should both be low for the best efficiency.

In Fig. 10 it will be noted that the natural-draft chain-grate

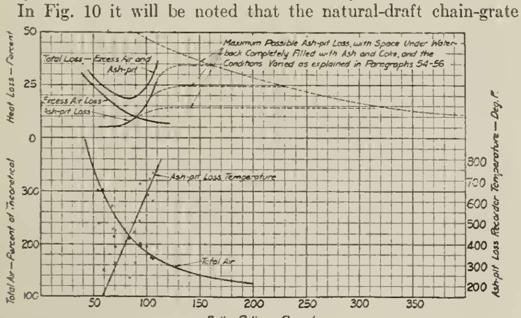

Fig. 11 Characteristic Loss Curves, on Basis of Boiler Rating, of Natural-Draft Chain-Grate Stoker as Operated in Station B

stoker in question, as it was being operated at this time, gives the best efficiency at about 210 per cent total air, with a loss of 18 per cent due to excess air and unburned coal. We all know that better results than this can be obtained under suitable load conditions with good operation and the right kind of coal, yet these curves indicate that there is a tendency for the losses to increase very rapidly as the fire changes to a shorter or longer condition from the most economical point.

The air having free and equal access to all parts of the grate takes the path of least resistance through the fuel bed and develops holes very rapidly when once started. In many plants the boilers are operated with the damper wide open. If the maximum amount of steam is not needed the fire burns short. If more steam is needed the stoker is speeded up and a little greater proportion of the grate area is covered with active fuel bed. In other words, the steam pressure is regulated by means of excess air. Fig. 12 shows this very nicely, as the air flow remains practically constant and more or less steam is produced as the coal is fed into the path of the air.

Fig. 11 shows the excess-air and ash-pit losses plotted on a basis of boiler rating. The total of these two losses has its lowest value of 18 per cent at about 90 per cent rating. At lower ratings the excess-air loss increases rapidly and at higher ratings the unburned-coal loss increases even more rapidly.

One naturally wonders whether the ash-pit loss would continue increasing at the rate indicated by the slope of this curve if the boiler were operated at still higher rating. The limit in this direction is reached when the space under the water back is completely filled with ash and coke. The percentage of combustible lost when operating with the space under the water back completely filled with ash and coke combined, will depend upon the percentage of ash in the coal, the coal-gate opening, and the height of the water back above the grate, and will be practically independent of the speed of the grate.

If the increased rate of combustion is obtained by increasing the gate opening and the intensity of draft, leaving the grate speed and the space under the water back constant for a given percentage of ash in the coal, a decrease in the ash-pit loss will result as shown by the upper dotted curve at the right of Fig. 11, because there will then be more ash per square foot of grate and therefore less space left for coke under the water back.

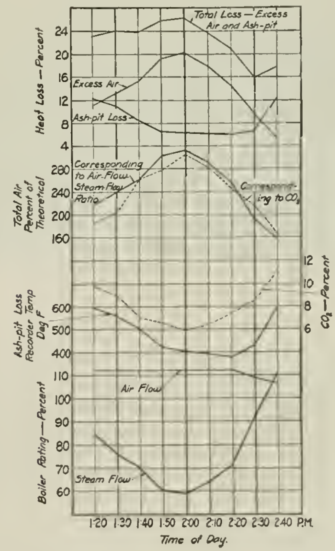

Fig. 12 Log Showing Change of Fuel Bed on Natural-Draft Chain-Grate Stoker as Operated in Station B

For any given relation between gate openings and space under water back the percentage of combustible lost would decrease with increased percentages of ash in the coal, and should of course remain constant for different ratings. A change in the height of the water back would also have a similar effect, the percentage of ash-pit loss remaining the same for all ratings in both cases so long as the space under the water back was kept completely filled and increased ratings obtained by increasing grate speed.

If the fire burns thinner, the ash-pit loss will be decreased for any of the foregoing conditions and the excess-air loss increased.

It is believed that characteristic curves like those shown in Figs. 10 and 11 will be very helpful in obtaining the best results from natural-draft chain-grate stokers. By means of such curves we should be able to accomplish better results in the arrangement of water backs, regulation of coal gate, grate speed, draft, etc., and also assist the fireman in obtaining the required amount of steam with the minimum loss.

Road Building and the Mechanical Engineer

Their Problems in Relation to Road-Building Machinery Presented Under the Auspices of the Materials Handling Division at the A.S.M.E. Spring Meeting

THE avenues of transportation of most importance to the greatest body of the public are the highways of the country. During the last five years highway construction has passed through a period of stress, which has focused attention on the proper application of machinery to the building of highways. The Materials Handling Division of the A.S.M.E. in devoting its Spring Meeting session to this subject afforded an opportunity for the contractor to meet with the engineer to discuss all phases of the problem.

While the extensive use of mechanical equipment may be of help to the road contractor, there is the added problem of increased overhead with the necessity for continuity in the operation of expensive equipment, calling for a complete understanding of the contractor's needs by the mechanical engineer.

The papers presented at the Chicago meeting emphasize to the contractor the importance of a careful planning of road-construction operations to better utilize mechanical equipment. There are no statements of principles by which the road contractor may be guided in the choice of equipment for a particular job and the presentations were made in the hope that their discussion would lead to the enunciation of such principles.

The meeting was also arranged with the idea of making clear to the mechanical engineer his field in the improvement of design of mechanical equipment for road-building purposes. The standardization of various types of apparatus is stressed in the papers and the importance of the publication of engineering data in regard to these various types is strongly recommended.

Road-Construction Plants

By B. H. PIEPMEIER,[1] SPRINGFIELD, ILL.

SUCCESSFUL road work offers more possibilities for different types of plants than perhaps any other single line of building construction, and every section of road to be built is a field for intensive study and investigation by the engineer and contractor. A thorough examination of the road plants in operation for the past few years shows clearly the need of more careful study of plant problems than is ordinarily given by engineer or contractor.

A successful road contractor in Illinois states: "No equipment should be purchased by a contractor unless he has sufficient work in view to enable him to practically pay for the equipment with a reasonable profit." If this rule were followed by more contractors, on many jobs, there would undoubtedly be less equipment and more profit. Such a statement should in no way discourage the road contractor in equipping himself thoroughly to do economical road work, but should force him to make a more complete analysis of his job before he invests in a road-building plant.

Small Construction Unit Advantageous—Duplicate Units Desirable

In general, the building of a system of roads requires the installation of a number of small plants in preference to a few large plants. This has been particularly true in the past on account of (1) the contractor's inability to secure experienced and capable superintendents for handling large-plant operations; (2) railroad transportation falling short in the delivery of sufficient materials to keep large plants working efficiently; and (3) frequent breaking of the machinery required in large road-construction plants—the breakdown of one machine very often delaying the entire plant operations and causing undue expense.

The small construction unit necessitates doing many operations by hand at somewhat greater expense than if done with machinery; however, when the final analysis is made, the small unit will show considerable efficiency on account of the possibility of its operating many times independently of any one particular machine out of service through breakdown.

Conditions existing during the past few years have made it impossible for the contractor with a large plant layout to show a fair profit. As soon as labor and transportation conditions become more stabilized, the large plant will show a much greater efficiency.

Contractors must give considerably more thought to the design of road plant so that its successful operation may not be wholly dependent upon one piece of machinery. Many successful road contractors realize already that to insure a constant and uniform output, it is economy in many instances to duplicate machines. Some contractors have installed a duplicate pumping system for the water supply, which is vital to the successful and economical operation of the road plant, and the additional cost of the duplicate unit is small compared to the advantage of being able to operate the plant without a delay.

In many instances duplicating concrete mixers has prevented a complete shutdown of operations. The average road job may not always justify a duplication of the mechanical units, but where a large season's work is required, a serious investigation of the advantage of the duplicate units should be made.

Transportation of Materials

The transportation problem in road building is one of the most important factors in the economical construction of roads. Consequently this part of the plant operation should be given a great deal of study. The transportation cost, should not only be estimated on the basis of the ton-mile cost but the effect it may have on the cost of operation of the remainder of the construction plant should be taken into consideration. Hauling cost varies from 20 to 40 cents per ton-mile. In a season's work a saving, therefore, of but a few cents per ton-mile may amount to several thousand dollars. The actual hauling costs may be exceedingly low, yet if the delivery affects the maximum output of the remainder of the plant, the inefficiency should naturally be charged against transportation cost.

Inasmuch as most specifications now prohibit storing road materials upon the subgrade, the road contractor is compelled to provide for transportation in one of two ways. He must deliver materials from his material yard to the road by industrial-railroad equipment or by truck. The industrial equipment, while expensive in first cost, will enable the contractor to complete his work with a minimum amount of trouble under normal conditions and regardless of weather, the average industrial equipment will insure a more uniform delivery of materials than any other unit that may be used. The chief objection to the industrial unit is that it is limited to road construction with grades ordinarily less than 4 per cent and a minimum number of railroad crossings. Further objection would be that the high initial cost demands a large mileage of roads be built each year in order to absorb the interest on the investment and the depreciation.

The other method of delivery is by truck or team. In recent years truck delivery has superseded team delivery, being more rapid and delivering material to a paving mixer or from a mixer direct to the road with less disturbance to the roadbed. Truck transportation of road materials is very flexible and therefore suited to more different sections of work than perhaps any other method of transportation. It is especially suited to the delivery of mixed concrete from a central plant to the road being improved, and to the delivery of proportioned batches direct to the paving mixer or to a

dustrial line which in turn delivers them to the paving mixer.

Delivery of Concrete from Central Mixing Plant

During the past few years the delivery of mixed concrete from a central mixing plant direct to the job has been attracting considerable attention. This method is worthy of study as it enables the contractor to centralize operations and in many instances to economize in plant and operating expenses. The central mixing plant should be reasonably uniform in design and simple in operation. A study of the central mixing plants in use during the past two years shows no two very similar in design. It would seem possible that unloading aggregate and cement from railroad cars, mixing the materials to the desired proportions and consistency and turning out a mixed concrete, could be standardized to such an extent that central plants could be simplified and made more economical in operation. It is hoped that the mechanical engineer and the equipment designer will assist in the design of a practical and economical central-mixing-plant unit.

Although central mixing plants may be fairly uniform in design, the delivery of the concrete from the plant to the road will vary considerably to suit the existing local conditions. Mixed concrete may be delivered by industrial equipment, provided the hauls are

Fig. 1 Material Yard, Showing Arrangment of Loading Bins and Storage Pile

Fig. 2 Material Yard, Showing Arrangement of Loading Bins and Storage Piles when Stiff-leg Derricks are Used

reasonably short and the equipment is designed for small loads with considerable speed in transportation. The small pneumatic-tired truck will usually prove the most efficient machine for delivery of mixed concrete, taking the individual batch of mixed concrete direct from the mixer to the road being improved in the least possible time.

Use of the Pneumatic-Tired Truck

The pneumatic-tired truck is essential when speed is an important factor in delivery and where it is necessary to do considerable hauling over the subgrade. This truck will usually reduce the load on the subgrade to less than 125 lb. per sq. in. of surface, and this pressure, even though frequently applied, does not seriously injure or displace a prepared subgrade having average conditions.

over earth roads with trucks when the roads are muddy or during rainy periods. However, the road may be materially improved and the truck used practically the entire construction season if the road is constantly maintained by the use of the road drag and given an application of half a gallon of oil per square yard of surface early in the construction season.

The light pneumatic-tired truck may also be used for the de-

Fig. 3 Four-bag Batch of Materials Delivered and Dumped Directly into Skip of Mixer

Fig. 4 Three-ton Trucks Used for Delivery of Mixed Concrete from Central Mixing Plant

livery of proportioned batches of aggregates direct to the paving mixer on the road being improved. There are now on the market many types of batch boxes and dump bodies which permit the batches to be dumped directly into the skip of the paving mixer. This method has proved to be very satisfactory. It differs from the delivery of mixed concrete in that a paving mixer is used instead of a stationery building mixer, and most of the operations of the contractor are out where the road is actually being laid.

Improvements in Design of Equipment Desirable

The plant investment of the road contractor of today is entirely too expensive compared with the work accomplished during a single construction season or from one particular installation of a construction plant. From $60,000 to $100,000 worth of plant equipment is frequently set up to build less than ten miles of highway. This is equivalent to charging off $2500 to $3000 for equipment against every mile of road built. It is doubtful whether there is any other building construction in which so much depreciation and interest on plant investment must be charged off on so small an amount of work. The mechanical engineer, equipment designer and contractor should apparently spend more time in the design of road-construction plants in order to insure a greater output with less initial investment.

Many of our road-building machines are being made larger, more cumbersome, and more expensive each year. The fact that road-building machinery is subjected to more severe use than perhaps any other machinery used in building construction has induced the manufacturer to add to his equipment each year to insure

more rigid construction. Many machines, such as the concrete paving mixer, can undoubtedly be completely redesigned and a machine produced much smaller in size, to mix more concrete and be less cumbersome on the job.

Mixer manufacturers have continued to improve the design of their paving mixers by following the same principles of mixing that have been in use for many years. It seems absurd that we must have a concrete paver costing from $8,000 to $12,000 and weighing from 10 to 15 tons that will lay less than two miles of 18-ft. concrete road in thirty days. It seems absurd also that we should still be using mixers that require 60 seconds of time for the mixing of aggregate and cement when it should be possible to do the same amount of mixing by some mechanical means in less than 15 seconds. If such a machine could be produced, a one-bag paver would turn out as much concrete as our present four-bag pavers. The present paver is also designed so that the mixing is concealed from the view of the mixer operator. This prevents absolutely the uniform consistency essential in securing a good concrete.

Fig. 5 Central Mixing Plant, Showing Material Storage

If the mixer designer can produce a smaller machine having a greater output per hour of operation and so designed that the consistency of the concrete produced can be controlled by the operator instead of by some unsatisfactory mechanical means, the results will be a wonderful aid to the road-building industry.

Also Room for Improvement in Railroad Equipment

It also seems possible that a very material improvement can be made in the present railroad transportation equipment. Practically all road contractors now unload aggregates from open-top cars by means of clam shells. This method is not always the most economical, but the contractor is forced to use it as he cannot secure all hopper-bottom cars he might desire. On account of the large volume of road materials to be delivered by railroad cars, some type of car should be designed that would permit of more rapid unloading by more economical methods. If this is not done, it is hoped at least that open-top-car manufacturers will improve the design of their cars and make them so that they can be more easily unloaded with clam-shell equipment. Not only would such improvement aid the individual unloading the car, but the railroad company would add to the life of its equipment.

Many open-top cars are now designed with projecting angles, rivets, bolts, braces, timbers, etc., which interfere with the efficient operation of the clam shell. It is difficult to understand why railroad cars could not be designed so that the interior of the car would be perfectly smooth. In fact, it would be practicable and economical for all open-top cars to be built with a fillet having a radius of about 18 in. in the bottom angle at the ends of the car. The curved bottom angles would permit the cars to be emptied more rapidly and economically either with hand shovels or clam shells.

Further investigation should also be made of the use of open-top removable batch boxes for railroad transportation of materials. While the substitution of standardized batch boxes for open-top cars would be a very radical departure from present equipment, the average construction plant could be designed to handle the boxes much more economically than the loose materials.

Mechanical Needs in Highway-Construction Machinery

By R. C. Marshall, Jr.,[1] Washington, D. C.

The interest of the mechanical engineer in highway construction centers in the equipment used. This equipment has made great strides in recent years and will undoubtedly continue to do so, yet the equipment needs for road building might be called comparatively simple. Consider a concrete road. All the average road builder needs is a light, portable plant capable of handling, mixing and finishing 400 cu. yd. of concrete every day, with no delay for repairs.

The charge has been made that modern road-building methods have so increased overhead expense that they have accomplished little saving. This may be an exaggeration, but the elaborate equipment now used has undoubtedly increased the overhead to such a degree that steady output of the plant is essential to financial success.

In order that this overhead expense may be kept within reason and highway costs estimated with profitable accuracy, it is essential that contractors have equipment capable of maintaining a steady flow of materials; first, from unloading point to mixer, and second, from there to the finished road. This is the problem confronting the field force and one which must find solution if road building is to become financially safe. Until further development of equipment can assure more continuous performance, construction companies must insure themselves against the loss caused by frequent delays.

The slogan of the designer should be, "Make the machine foolproof." Increased strength may demand heavier parts and increased first cost, but this is inconsiderable compared with the loss due to one breakdown.

Last year's work, on account of spasmodic and continued delay, was not conducive to a careful study of equipment needs. Transportation troubles so disrupted operations that contractors were obliged to grasp at any expedient to push their work. This, combined with labor and material scarcity, left them little time for a constructive study of their specific equipment needs. Of one thing, however, nearly every road builder is keenly aware. His work suffered heavily from frequent interruptions which disorganized his force and increased the unit overhead cost. Delays from transportation difficulties and equipment trouble caused the overhead expense to absorb a large portion of his profit and in some cases much of his capital. Delays caused by equipment trouble are traceable to three main causes: First, lack of skilful mechanics; second, lack of standardization in design, and third, lack of accurate information concerning the adaptability, capacity and operation of machines.

The lack of skilful mechanics concerns both manufacturers and contractors. An equipment company may expend much time and money in perfecting designs or improving the quality of the workmanship, but if its machines are placed in the hands of incompetent operators, the money spent for them is wasted. Incompetent operators can readily offset the advantages of efficient equipment and well-planned work. Under careless handling the heavy delays for repairs mean a loss of money to the road builder and to the manufacturer a loss of that valuable asset, good will.

An economical solution of the shortage of good operators might be effected by establishing for them a short course of instruction during winter months when construction is slack. Savings effected in the field by competent operators would amount to many times the cost of their instruction. One of the worst obstacles to continuous output would thus be removed.

Plenty of Opportunity for Standardization

The second significant source of delay is a lack of standardization in equipment where standardization is possible. Road-building

[1] General Manager, The Associated General Contractors of America.

manufacturers, and to be prepared even for the usual run of minor field repairs on all machines requires a more or less elaborate machine shop. The financial burden of carrying duplicate units or a sufficient number of spare parts is too great for an already heavy overhead, and in order that this expense may be held within reason, greater interchangeability of parts should be made possible.

The amount of saving that might be effected through standardization of road equipment is not generally appreciated. To build a medium-sized high-type section requires a daily field payroll of three or four hundred dollars and an overhead of probably another hundred. So that five hundred dollars per day is not an unusual cost. An employee cannot be laid off every time a breakdown occurs, and since the overhead goes steadily on, fifty dollars an hour may be considered an estimate of the cost of equipment delays.

probably results more frequently in disaster, is a lack of unbiased and authoritative information concerning the adaptability, capacity and operation of machines. Lack of such information has already brought disaster to numerous individual companies, both old and young; and as new concerns are constantly taking up road work, it is essential that they secure authoritative mechanical advice.

What contractors need is accurate data showing under what conditions a certain type of machine is suitable, how long it may reasonably be expected to last, and what output it can deliver under normal working conditions. If this information can be made available, construction companies may be relied upon to intelligently select machines. They will then be able to coördinate their plant and estimate their costs.

Planning and Organizing a Road Job for Mechanical Handling of Material

By C. D. Curtis,[1] Washington, D. C.

The last few years of the decade just closed ushered in a new era in road building. Legislative action stimulated in a large measure by the Federal Aid Road Act has been taken in practically every state, making possible the inauguration of an unprecedented country-wide program of highway improvement. The rapid expansion of the use of the motor vehicle has created an insistent and growing demand for more and better highways. It so happens that this movement has had its greatest growth during a period of rising costs, the crest of which has only recently been passed; so that, along with the urge for more and better highways, there has been always in the mind of the highway engineer the necessity for rigid economy of labor and effort. Fortunately, the inventive genius of the country has not been idle during this period and many new and improved types of road machinery and equipment have been put on the market. The introduction of this new equipment has made it possible to perform mechanically many of the operations connected with road building not only cheaper but better than they can be done by the older hand methods.

While every one will concede that all construction jobs should be carefully planned and well organized for the handling of materials, it must be admitted that this is not always done. In the past too little thought and study have been given to this preliminary phase of the work. Until recently, however, road work has been handled on a comparatively small scale, and the cheaper types of construction prevailed. An extensive plant was not required and the evolution brought about by the general adoption of higher types of construction and the growth of construction programs is still under way. It is unfortunate, but nevertheless a fact, that most jobs are equipped without giving to their planning and organization a proper amount of careful study. As a result expected profits shrink and may even become actual losses. Improperly equipped jobs can be classified under three heads:

1 Too much plant,
2 Lack of plant, and
3 Unbalanced plant.

With too much plant on a job the efficiency of operation is lowered, and although fairly satisfactory progress may be made, the cost will be too high. Rental or interest on investment and depreciation charges continue regardless of output. On an under-equipped job it is necessary to resort to labor which may be less efficient and more expensive. The progress of the work is likely to be delayed and total costs increased.

Of all the improperly equipped jobs the ones that have an unbalanced plant are probably most common. They are the inevitable result of equipping without planning. The several units making up the plant may be efficient mechanically when considered alone, but totally incapable of being worked smoothly and continuously together. On such jobs efficient operation cannot be secured. The plant investment might, and probably would, be higher than for a balanced plant. The season's profits, however are certain to be lower than anticipated.

Classification of Road-Building Work Based on Desirable and Practicable Rate of Progress

In the author's opinion a classification of road-construction jobs based on the desirable and practicable rate of progress is feasible and would aid the contractor or engineer in selecting the proper plant. In determining on such a classification several factors would enter into the consideration, chief of which would be the size or length of the project. Another factor would be the problem of satisfactory detours and the probable economic loss to traffic. The cost, of course, would be affected by the classification. Ordinarily a higher rate of progress would be required on a large job than on a small one. The extra cost, then, of assembling and operating a large plant capable of rapid progress would be spread over a large yardage. It might easily happen, however, that the economic conditions would warrant requiring very rapid progress on a comparatively small job. This would change the classification and increase the cost of the work, but the bidder would know just what to expect.

In connection with concrete-road jobs there might be three classes, such as:

A—Jobs on which equipment with a daily capacity of 1000 ft. of 18-ft. roadway would be required;

B—Jobs on which equipment with a daily capacity of 500 ft. of 18-ft. roadway would be required, and

C—Jobs on which equipment with a daily capacity of 250 ft. of 18-ft. roadway would be required.

In the case of Class A jobs it would ordinarily be desirable to equip with at least two complete operating units. This would insure continued, even though retarded, progress in the event of a breakdown of one unit.

Such operations would, of course, be contingent on the weather and other conditions beyond the contractor's control, but the classification would give a more definite idea of the requirements and enable the engineer and all bidders to estimate on exactly the same basis. The classification conditions should be covered in the specifications.

Necessary Limitations Imposed by Specifications

Unnecessary refinements in the specifications which are met with at times usually lead to difficulties in operation and should, in the author's opinion, be avoided, especially where enforcement increases the cost of operation for minor or questionable benefits. There are, however, certain limitations which make necessary an intimate knowledge of the specifications under which work is to be performed. Examples of these limitations are:

1 Time limit on depositing of concrete after mixing. This limit would have a direct bearing on the location of central mixing

[1] Assistant to Chief, Bureau of Highways, Department of Agriculture.

plants and the equipment required for handling both the aggregate and the concrete.

2 Definite requirements relative to concrete mixers such as water-measuring devices, boom and bottom-dumping bucket, etc. Such requirements are small details, but must be met and so must be considered in selecting equipment.

3 Materials for concrete not allowed on subgrade. This feature is very important and makes necessary a careful study of the project in the field. Several alternative methods of handling the materials may be possible, and the most economical and efficient one can only be determined after a consideration of all the conditions. One location might be well adapted to the use of industrial-railway equipment, while in another location this method might be entirely impracticable and hauling of proportioned batches of aggregate and cement in trucks the most feasible. The central-mixing-plant method might be the proper selection in some other location. In the case of a large job conditions may vary considerably on different sections of the same job.

Precautions to be Taken in Selecting Equipment

In selecting equipment for a project, everything bearing on the situation should be considered. The source of materials to be used, whether local or imported, condition of roads to hauled over, width of available right of way, trackage and storage facilities available at receiving points for materials requiring rail transportation, maximum grades, water supply, availability of common labor and teams, and length of working season are some of the factors which should be looked into and studied before deciding on the type of plant to be used. In this connection the engineer may and should render all possible aid to the contractors. The preliminary investigations and detailed surveys made by the engineer give him much more information than the contractor can secure readily in his preliminary field inspection of the project. If the engineer knows that the conditions, even though not apparent, make the use of certain types of material impracticable, this information should be given to the contractor.

A feature which perhaps is not germane to this discussion but which is very important and deserves a few words, is the desirability of considering the source of the materials to be used with respect to the possibility of continuous rail-transportation service. Without a reasonable assurance of a continuous supply of materials throughout the working season, an elaborate plant layout may become much more of a liability than an asset. By arranging to ship and store materials during the season of light demand for open-top cars, for use during periods of car shortage, a continuous supply of materials can be secured. Such an arrangement may considerably alter the selection of equipment for handling the material. Strong arguments may be made against the plan of advance storage of materials in states where estimates for materials delivered are not allowed, but the extra cost of storing materials may be more than offset by the gain due to continuous operation during the construction season.

It is desirable, of course, when possible, to avoid all unnecessary rehandling of materials. Where the materials can be unloaded from cars or loaded from the quarry or pit directly into containers for transportation to the job and in addition can be deposited in the mixer, in the case of concrete, without touching the ground, a great advantage is gained. In addition to being kept clean and free from mixture with foreign matter, the item of waste is very greatly reduced.

Exclusive Development of Large Individual Units Undesirable

In some states, by adopting the practice of letting large contracts for long stretches of construction work, large contracting companies have been induced to enter the highway field. They have brought trained operating organizations to the work and have put extensive road-building plants on their jobs. There is wisdom in such procedure whenever possible, for, of necessity, a great many road jobs are and will continue, for a variety of reasons, to be of comparatively short length. Letting contracts in both large and small sections gives both the small contractor and the large a field of operation and greatly expedites the carrying forward of a large program. The small contractor, acting as his own superintendent and operating with but little mechanical equipment, has but little overhead and can compete on a small job with the large contractor operating a large plant and carrying heavy overhead expenses.

Road building differs from most other construction activities in that the operations are conducted along an extended narrow path. The failure of one link may interrupt the work of a whole operating chain. This fact, in the author's opinion, makes the present tendency toward the development of large individual units somewhat questionable. When a large unit is used every precaution should be taken to insure its continuous operation.

Importance of Maintaining Organization the Year Around

One of the greatest handicaps which the road builder encounters in the northern states is the short construction season. Continuous operation is impossible and each season it is necessary to organize new construction forces. It takes some little time to organize a new outfit so that the work will proceed satisfactorily. In the case of the skilled mechanics and foremen, an attempt should be made to retain their service the year around. They can be utilized during the winter in repairing equipment and putting it in first-class condition for the next season's work. It may even be necessary to furlough them for a time with pay, but the investment will bring big returns in added loyalty to the company and increased devotion to duty. The average man appreciates a square deal and will show it in increased efficiency. The use of an extensive plant requires skilled operators, and, once trained, their services should be retained. Efficiency of operation in road work depends on the proper functioning of all the separate units. The mechanical units function properly only when properly handled.

On large jobs where more than one plant or complete operating unit is used, the spirit of the organization can be kept up by introducing friendly competition. The rivalry between two outfits to reduce costs and increase yardage has a very healthful effect on progress and incidentally on profits. The author recalls a bituminous-concrete construction project on which four separate mixing plants were used. One of the plants was an old, makeshift affair, but was handled by an energetic suprintendent who had old and loyal employees of the company as foremen and mechanics. The output and costs compared more than favorably with the new plants, due entirely to the better morale of the men. It pays to retain loyal and efficient employees.

A New Alloy Steel

An alloy imparting to steel toughness, great density, a high elastic limit and ultimate tensile strength, and machinability even when showing qualities of extreme hardness, was developed during the war by Dr. L. P. Burrows. Tests conducted by the Ordnance Department of the United States Navy proved so satisfactory that the alloy was adopted for use in the manufacture of naval artillery material, and is now being made in a half-dozen plants by the open-hearth and crucible methods. The *Iron Trade Review* describes, in its issue for April 7, the process of manufacturing this alloy. Nickeliferous ore obtained in the Sudbury district of Ontario is first crushed and then treated in a revolving cylinder from which oxygen is excluded and into which a gas is introduced containing 89 per cent hydrogen and 10.8 per cent nitrogen. It is then smelted in a crucible or other suitable furnace and then thrown out on the floor. In about 24 hours the product disintegrates into a purple-colored powder. This is refined further and cast in pigs, the yield being estimated at from 1400 to 1600 lb. of metal per ton of ore. The chemical analysis of the alloy is as follows: Silicon, 2.51; iron, 52.89; nickel, 3.98; manganese, 0.046; sulphur, 1.90; cobalt, 0.15; arsenic, 0.11; copper, 0.59; phosphorus, 0.12; tungsten, 0.24; chromium, 2.61 per cent, and varying traces of rare earths and members of the platinum group.

Numerous independent tests of steel containing 1, 1.5 and 2 per cent of the alloy have been made at the Philadelphia and Brooklyn navy yards, several testing laboratories and a number of metallurgical plants. It has been found that specimens with a Brinell hardness of more than 364 are easily machined, a behavior which is contrary to the general assumption that the machinability range lies below 340. Mystery also attaches to the alloy due to the fact that when it is used in electroplating, it seems to impregnate the material instead of merely plating it. There are indications that the material resists corrosion.

Requirements of the Engineering Industries and the Education of Engineers

By MAGNUS W. ALEXANDER,[1] NEW YORK, N. Y., and DUGALD C. JACKSON,[2] CAMBRIDGE, MASS.

A combination of empiricism and training in rational science is needed in engineering education because it is needed in the engineering industries, and this consideration has led to various plans for placing engineering students within the influence of industrial operation, the most common being for engineering college graduates to enter industrial establishments as "cadets," "engineering apprentices" or "student engineers."

The first comprehensive, organized plan for bridging the gap between academic and practical training of the young engineer was made operative in the United States in 1906 when Herman Schneider, Dean of the Engineering Department at the University of Cincinnati, organized a cooperative engineering course in connection with the metal-manufacturing plants of that city. Schneider's ideas lie at the base of the cooperative plan which the authors succeeded in organizing a few years ago in connection with the Massachusetts Institute of Technology and the Lynn Works of the General Electric Company, and which is described at length in the present paper.

This cooperative engineering course covers a total of five years, the first two being identical with the freshman and sophomore years at the Institute and the last three being divided between instruction in theory at the Institute and instruction in practice at the Lynn Works. In these last three years the total time occupied in studies at the Institute and practice at the Works is eleven months per year. The first term of the cooperative period, extending through thirteen weeks, is spent at the Works by all of the students during the summer period immediately following the sophomore year at the Institute. The succeeding terms of similar duration are spent alternately by each half of the student group at the Institute and at the Works, while the final term is spent by all the students at the Institute for additional advanced instruction and the preparation of a master's thesis prior to the college commencement.

During their assignments at the Lynn Works, students are subject to the usual rules and regulations applying to employees of the General Electric Company, and on a full week's work schedule receive compensation at the rate of $21 per week at the beginning of the course and $24 at the end.

The joint supervisory committee of the two institutions believe that this experiment in cooperative engineering training will exert a most beneficial influence upon the relationship of the engineering college to industry and upon the activities of each. They are clear in their own minds, however, that the cooperative training in engineering must not and cannot replace the regular engineering courses at colleges which in the nature of things must cater to the majority of young men seeking a thorough training in the engineering sciences, and many of whom do not enter the manufacturing industries. The cooperative training, however, is destined to become a vital integral part of a comprehensive system of engineering education, to the detriment of none of the other parts, but to the mutual benefit of all, and is particularly important to the manufacturing industries of the nation.

> Upon the subject of education, not presuming to dictate any plan or system respecting it, I can only say that I view it as the most important subject that we as a people can be engaged in.—Abraham Lincoln

NO EDUCATION which is sound at base is without vital interest to the engineering industries. Herbert Spencer a generation ago defined the objects of education in five divisions:

1 Those activities which directly minister to self-preservation

2 Those activities which, by securing the necessaries of life, indirectly minister to self-preservation

3 Those activities which have for their end the rearing and disciplining of offspring

4 Those activities which are involved in the maintenance of proper social and political relations

5 Those miscellaneous activities which make up the leisure part of life devoted to the gratification of the tastes and feelings

It is clear that the first three aspects of education are very specific and relate to the individual or to himself and his immediate environment, while the last two are more general and relate as much to the associations of the individual as to the individual and his immediate environment. An education comprising all five aspects qualifies its possessor for "complete living," which, according to Spencer, is the real object of education. That industry is vitally concerned with the first three aspects is quite obvious and easily demonstrated. Thus, propaganda for "safety first" in industrial establishments is an impressive extension to mature workmen, of education for self-preservation which experience impresses on a child almost from birth; and the expense and effort for carrying forward this branch of education would not be sh ul-dered by industry were it not recognized that the safety of workmen is fundamental both as a matter of humanity and of conservation.

On the other hand, need for securing the necessaries of life is at the root of all industrial production and activity and is the motivating force for elementary work education, while the essence of education for artisanship seeks to broaden and refine this primitive activity. And finally, interest in educational effort for the development of family life, while primarily social in character, is equally important to industry both from the standpoint of self-preservation and the stabilization of man's character arising from family associations and responsibilities.

Industry is therefore vitally concerned with these three primary functions of education, and to the extent to which these aspects are allowed to languish, industry will suffer.

Although primarily of social importance, the two last-named aspects of education according to Spencer, namely, education for good citizenship and for proper enjoyment of leisure, have their bearing and effect upon the conduct of industry. Reason and experience show that successful industrial practice, useful alike to producers and users of industry's products, cannot be long sustained except in communities with a stable citizenship, rooted in a sense of right as between man and man. Wide interest in industrial circles in "Americanization" demonstrates the tacit recognition of the importance of education for thoughtful, steady citizenship. Similarly, not only as part of citizenship development but in its reaction upon the work period of life, the rational enjoyment of leisure as the result of adequate education comes within the domain of industry's interest in education.

In this connection it is significant to reflect that the settlers of New England founded schools and colleges simultaneously with the clearing of the land for their dwellings. These early impulses and policies exerted their influence throughout the later upbuilding of the country, and consequently the establishment of schools has played a notable part in our national development. The hardy frontiersman seldom blazed a trail which schools did not promptly follow.

This record for school education is not peculiar to the American people, but it has been peculiarly universal with them, and a comprehensive educational system has resulted which reaches even to the remote byways of the country. Yet an educational system to meet the needs of our country must be something more than merely a widespread school system in touch with all of the people. The universality of education must be supplemented by those special forms of education which are necessary for the fullest development of each branch of human endeavor and service. In

satisfaction of this condition a great variety of specialized schools have been established: on the one hand divinity schools, law schools, medical schools, engineering and other professional schools, and on the other, trade schools and vocational schools of various kinds.

Types of Engineers Needed by the Engineering Industries

To conform to the scope of this discussion let us now consider more fully the aim, development, and result of engineering education. In the consideration of any plan of education as preparation for a specific field of activity it is necessary that it be tested with regard to the needs of that field.

What do the engineering industries require in the young men who as engineers are seeking to make this the field of their life work?

Industry is concerned with the transformation of the raw materials of nature into forms more readily adopted to the needs and desires of mankind, through the application of the forces of nature and of man's knowledge and power. This is kinetic in character, a process constantly changing and developing as new materials become available or as new knowledge points the way to improvement.

It is clear, therefore, that first there is need for the pioneers of science, the men to whom we may look to extend the frontiers of knowledge, to delve deeper into the mysteries of nature that new processes may be developed for the utilization and conservation of our natural resources. These men, while having little to do directly with commercial production, must nevertheless have an appreciation of the scope and organization of industry in order that their efforts may be directed along the lines of economic needs. Their chief requirement, however, is a thorough and intimate knowledge of the various branches of science and of the past as well as of more recent developments of practice and theory. As used by engineers, theory means a working hypothesis founded on known facts and experiences which may be utilized to guide progress beyond the margin of past experience. Theory is not antagonistic to practice, but is founded on experience and is a guide to progress.

The second need of industry for engineers arises out of the fact that the advance of industry in the last century has produced an organization of vast complexity and delicacy of adjustment, an organization calling for increasing numbers of efficient executives and administrators. They must be men with industrial training of a high order, competent to conceive, organize and direct extended industrial enterprises of broadly varied character. These men must be keen, straightforward thinkers who see things as they are and who are not misled by fancies; who are capable of quickly grasping the essentials of the many problems that arise, and who are trained in the orderly marshaling and correlating of facts and forces necessary to meet the daily problems that are incident to the functioning of the industrial organism.

But aside from a thorough knowledge of the physical and mathematical sciences, an adequate understanding of human character and of the trend of human progress is essential in order that these engineers may make the most of their abilities. To emphasize this fact it should be realized that over ten million people in this country are spending the major portion of their waking hours in the various processes of industry. This, then, makes it at once apparent how important it is that the engineering schools from which industrial leaders are to be recruited must teach the necessary knowledge of human nature, sound business methods, best means of effectively directing the human forces engaged in industry. Concerned more with the organization, correlation, and administration of mechanisms and productive activities than with the extension of scientific knowledge, they must address themselves in an increasing degree to the problems of the adaptation of the average human abilities to the requirements of those mechanisms and processes; but intimate knowledge of those physical mechanisms and processes must be a part of their intellectual equipment.

Methods of Preparing Prospective Engineers for their Professional Work

Generally the engineering industries need, therefore, three types of engineers: the scientist for discovery and for the instruction in fundamental laws; the practical specialist for application of science to the processes of industry; and the executive for administration and direction of the human forces. With this in mind we may now consider more definitely the problem of engineering education: namely, how most effectively to prepare the prospective engineer for the work he is later to perform.

The average student entering the engineering school at the age of nineteen to twenty-two years, has only a vague and uncertain understanding of the meaning and purposes of industry, and practically no understanding of the problems that will confront him when he enters the industrial field. His usual conception of what the college means is the acquisition of a body of facts handed to him by the teaching staff which in some way he will later on use to advance his own interests. He enters with an alert and inquiring mind and frequently full of enthusiasm for self-expression, but seldom with much unbiased effort at self-analysis or valuation.

Experience has shown that the usual method of taking this human raw material through four or five years of scholastic work without more than casual contact with the practical problems later to be met, frequently results in the neglect of, or superficial attention to, many of the studies essential to subsequent progress. Not infrequently it also results in a long and discouraging period of readjustment after graduation, during which the new engineer-recruit often endeavors to adjust industry to some of his false conceptions rather than to adjust himself to the new life he is entering.

There are two methods by which the engineer can acquire the knowledge needed for his professional work: the *rational*, wherein the solution of problems is obtained by means of direct reasoning from definite premises; and the *empirical*, which is based on experience and observation, and reasoning by balance of evidence. In certain fields of engineering the subjects dealt with are so complex and the knowledge regarding them so fragmentary that empirical or experimental methods must be resorted to almost wholly. In other fields the subjects are so open to analytical processes of reasoning, and knowledge regarding them is so well organized, that purely rational methods suffice for adequate solutions. In most instances, however, the conditions are such that a combination of the rational and empirical procedures should be used.

Broadly speaking, our engineering schools and colleges emphasize the former, while engineering practice depends largely on the latter. Rational methods are typified and developed by the study of the sciences, such as mathematics, physics and chemistry; and empirical methods are exemplified in the education derived from direct association with, and participation in, the activities and processes of industry. A combination of empiricism and training in rational science is needed in engineering education because it is needed in the engineering industries. A better balance must be established between the teaching of the sciences in the colleges, which should emphasize this part of education and resist any attempt to diminish its effectiveness, and practical education in industrial establishments, where it is rooted in production with consequent better appreciation of the value of time and money as elements of industrial activity.

This consideration has led to various plans for placing engineering students within the influence of industrial operation. The most common way is for engineering college graduates to enter industrial establishments as "cadets," "engineering apprentices" or "student engineers;" and sometimes engineering education during the undergraduate course is supplemented by practical industrial employment during the summer months. The value of the latter method of interweaving engineering practice with engineering education was emphasized by the late Frederick W. Taylor, man of genius and Past-President of The American Society of Mechanical Engineers, who advocated that each engineering student be required to spend a year or more in commercial shop employment before the end of his course of study in the college. Taylor recognized the weakness of the tandem relation of the college course and the subsequent student apprentice employment, and by his proposal approached the condition of intimately interlacing the time of these two. It is evident that European experience and practices served to stimulate his thought along these lines.

The West of Scotland Technical School for a long time has required its students to spend a period in the factories before completing their studies at the college. A like plan has long been in effect at the Royal Polytechnic School of Denmark and at similar engineering schools in other parts of Europe. Faraday House, a British school of electrical engineering, alternates its students in yearly intervals between the formal school and commercial engineering plants.

In the year 1906 the late Sir William White added all the weight of his great name and influence in British industrial circles to a report urging the importance to engineering students of interchanging time between the engineering school and engineering establishments.

The Schneider Plan for a Coöperative Engineering Course

In the same year the first comprehensive, organized plan for bridging the gap between academic and practical training of the young engineer was made operative in the United States when Herman Schneider, Dean of the Engineering Department of the University of Cincinnati, organized a coöperative engineering course in connection with the metal-manufacturing plants of that city. Prior to this, most of the engineering schools in the United States had urged their students to secure engineering employment during their summer vacations, and some had gone so far as to establish a system for crediting required work in the practice shops of the school by machine-shop employment during vacations, provided it was secured in approved shops and the factory superintendent certified to the extent, character, and satisfactory grade of work done by the individual student.

Schneider's plan is comprehensively dealt with by C. R. Mann in his important and suggestive report on Engineering Education issued in 1918 by the Carnegie Foundation for the Advancement of Teaching, in which The American Society of Mechanical Engineers took a part by participation in the Joint Committee advising the work. The report in part says:

> The Cincinnati plan was first formulated by Herman Schneider in 1899 while he was an instructor in civil engineering at Lehigh University. In 1902 Schneider presented a full statement of his scheme to the directors of several large industrial firms which were considering the establishment at Pittsburgh of a new technical school to give engineering training that would be better suited to industrial needs than that then given in the engineering colleges. This plan was abandoned when Mr. Carnegie founded the Carnegie Institute of Technology in the city of Pittsburgh. Finally in 1906 Dean Schneider found an opportunity to make his experiment at the University of Cincinnati.
>
> The mechanism of the scheme is very simple. The students are divided into two groups, one of which is assigned to work in industrial plants while the other goes to school. At the end of each bi-weekly period the two groups change places so that the shops and the school are always full-manned. In the shops the students work as regular workmen for pay, but the nature of their work and the length of time each stays on any particular job are subject to approval by the university. The emphasis of the school work is on theory and principles, but these are well interrelated with the shop work by "coördinators" who visit each student during each shop period and then meet the several groups during the university periods in special "coördination" classes for this purpose.
>
> The curriculum is completed in five years of eleven months each, so that each student receives twenty-seven months of university instruction. Since the regular four-year curriculum in other schools requires about thirty-six months of actual instruction, it would seem at first glance that the Cincinnati curriculum could not give as full a training in fundamentals as is given elsewhere. This inference, however, is wholly unwarranted because in the twenty-seven months of industrial work the student gets a vast amount of practical knowledge which is given in other schools in information courses, and because of the close coördination with practice which makes the theory more intelligible and significant to the students. The graduates of Cincinnati have unquestionably as extensive a training in theory as have those of other first-class schools. In addition, the Cincinnati graduates are able to command engineering positions at graduation without one- or two-year "apprentice" courses such as are required of men from other schools by the large corporations. . . .
>
> Schneider's experiment is clearly much more than a novel and inexpensive method of handling the shop work. It is an effort to create a type of school that meets the demands of an industrial age. It frankly recognizes that the present need is for masters of materials who can humanize industry. It tries to emphasize rather than to discourage the appraisement of values and costs, and endeavors to express idealism in the economics of life rather than build ideals that are unrelated to human experience.

Schneider's ideas have since been followed in the establishment of coöperative engineering courses at several educational institutions, and they lie at the base of the coöperative plan which the authors of this paper succeeded in organizing a few years ago in connection with the Massachusetts Institute of Technology and the Lynn Works of the General Electric Company.

Whatever weaknesses in major features or in detailed application Schneider's plan may possess, unstinted praise must be given him for his conception of the idea as far back as 1899, and for his persistence in pressing the proposal to a practical consummation in 1906.

Growing out of a close study of industrial and engineering educational methods as they seemed to be demanded by American industry, and stimulated by the development of the coöperative engineering course at the University of Cincinnati the paper was presented in 1908 at the Atlantic City convention of the American Institute of Electrical Engineers entitled The New Method of Training Engineers.[1] In this paper the merits and value of coöperative engineering education are analyzed and a strong plea is made for joint effort of college and industry for the comprehensive education of engineers. The paper deals somewhat at length with the method of interlacing theory and practice and the most advantageous time allowances for each. Arguments are advanced against the short periods of alternation between college work and industrial employment established under Schneider's plan—alternations at first of one week's duration, and later of two weeks' duration—and an improvement is suggested based on alternating periods of at least four or five weeks at the beginning, and of college semesters toward the end, of the coöperative course, with a full year of college training as a finishing work. Because the arguments then advanced in favor of longer periods of academic and practical instruction and in support of other major features of coöperative engineering education are pertinent to the discussion of the plan now submitted, the views expressed in that paper are briefly summarized here, as follows:

A serious study of this situation has led to the belief that the best engineering education can be obtained under a plan which provides that the teaching of the theory and practice should go hand in hand, and, so far as practicable, successive steps in the one should be based on similar advances made in the other, at such intervals as to permit of the most advantageous interplay of the two; and further, that the colleges should devote their whole time to the teaching of the theory for which they are so eminently adapted, leaving it to real workshops to initiate the student into practical work, for which they in turn are best equipped. From an educational standpoint this plan should prove efficacious, for mental conception of any activity is facilitated by the physical perception of a given process, as illustrated in the whole development of the human being; and on the other hand, mental visions are more firmly clinched by concrete application. Moreover, under such a plan the freedom enjoyed by students during the college career is happily interrupted by the stern discipline that must prevail in a business organization. This plan also trains and develops the young man in the very life to which he will devote his future efforts and gives him the love for it, which, after all, is necessary for his success. An arrangement of this kind, carrying with it financial remuneration during a part of the time, will attract to the engineering industries young men who are mentally and physically adapted, but who at the present time do not enter college for financial reasons or for lack of appreciation of the value of higher education. The poor boy, if otherwise fitted for it, will be given a chance to acquire a college education by "working his way" through college in activities that have a direct beneficial bearing on his future career. The influence of the college will therefore be extended and in no way restricted by the coöperative plan as contemplated.

The length of the alternating period is a very important element in this plan, for too long or too short a time may defeat the very objects which the coöperative course seeks to accomplish. In the light of the aims of the course previously advanced, short periods seem to recommend themselves. A year or even six months spent alternatingly at college and at the factory would, it is believed, fail to give that close coördination of theory and practice that is an essential feature of the plan; nor would it establish that balance between the college freedom and the factory discipline which has already been referred to as very desirable. Short

[1] Magnus W. Alexander, Trans. Am.Inst.E.E., vol. 27, p. 1459.

periods, on the other hand, will develop that facility in the young man's physical and mental make-up that will enable him to adjust himself quickly to the interacting influence of the college and the factory. The engineering apprentice should enter upon his factory work as a college boy with all the mental alertness and the inquiring mind fostered by the college; and he should return to the college as an industrial worker with the physical energy and the determined spirit of achievement that will be developed in a hustling factory organization. The attainment of these characteristics will to a large degree determine the success of the plan. Alternating periods of a day or even a week, to take the other extreme, might keep the young man's mind in a rather chaotic state, might not give the seed sown in the classroom and factory, respectively, a fair chance to take root. Such time arrangement, moreover, would seriously interfere with the best economy at the factory, and largely forfeit that sympathetic interest of the shop foremen and workmen which is not only desirable but decidedly necessary.

Attention is also called to the efficacy of an arrangement under which the periods increase in duration from the first toward the last year of the course, beginning perhaps with alternations of four or five weeks and ending with time elements of college semesters. In that way all the advantages of the coöperative course would be emphasized strongly at the beginning when they are of determining influence, and the economic consideration of the college and the factory would receive growing attention in later years as justified by the increasing importance of the work.

Coöperative Engineering Course Between the Massachusetts Institute of Technology and the General Electric Company's Lynn Works

This proposal of 1908 as above outlined in summary was seriously considered by a committee of representatives of the Massachusetts Institute of Technology and of the General Electric Company and was finally accepted by both institutions after the sympathetic coöperation of the president and the faculty of the Institute on the one hand, and of the officers of the company on the other, had been secured. Freshmen acceptable to both institutions were to be started on a six-year coöperative course with half of the total number of students in this course spending alternating periods of from six to nine weeks at the Institute and at the workshops of the General Electric Company, respectively. Meanwhile, however, the business depression of 1913 had set in and made postponement of the educational experiment advisable, affording at the same time opportunity for further reflection and study. This led to important modifications of the original plan, the principal one being that of accepting juniors rather than freshmen for the course, lengthening the alternating periods between college and factory to approximately three months' duration, and making the coöperative course last three years, predicated on a two years' college preparation but leading directly to the Master's Degree in Science. While the coöperative engineering students were to be recruited from the Electrical Engineering Department of the Massachusetts Institute of Technology, it was then clearly understood that the same privileges and the same conditions should later be extended to the students of the Mechanical Engineering Department and that in the future no difference should be made as between the two; it was also agreed that students from other colleges should be eligible for the coöperative engineering course if they could qualify for junior work at the Institute.

The advantages of these modifications appealed strongly to both institutions and a coöperative engineering course between the Massachusetts Institute of Technology and the Lynn Works of the General Electric Company was actually started in the summer of 1917 with a class of thirty students. Right from the beginning the experiment showed the earmarks of success and during the first year of its operation gained the support of the interested parties in both institutions. The exigencies of the war, however, in which the United States had meanwhile become involved, and especially the rules of the Students' Army Training Corps, the S.A.T.C., requiring all engineering students of draft age to be under military command and subject to drill, again interfered with the progress of the coöperative engineering course and necessitated its temporary relinquishment in the summer of 1918.

Undaunted by these unfortunate but unavoidable interruptions and more than ever believing in the efficacy of the proposed plan and in its value as an experiment in engineering education, the officers of the Massachusetts Institute of Technology and of the General Electric Company seized upon the opportunity offered by the cessation of war activities and the return to more or less normal conditions, and in the summer of 1919 reinstated the coöperative engineering course which has since continued in operation on an enlarged scale. Experience with this plan for now practically two years indicates quite clearly that, barring slight changes which may become advisable in the course of time, the plan itself is built on a sound basis of good pedagogy and good business principles. It would seem appropriate, therefore, to discuss here the principal features of the plan and the results so far achieved.

By agreement of the two institutions involved, a joint committee was appointed to supervise the coöperative engineering course and to make such changes within the limits of the accepted plan as may from time to time become advisable. The committee is headed by Dr. Frederick P. Fish, equally known as the country's most eminent attorney at the patent bar and as a keen student of educational methods and participant in their development, and moreover a directing factor in the councils of both institutions. Associated with him are, representing the Massachusetts Institute of Technology, Prof. Dugald C. Jackson and Prof. Frank A. Laws, the latter having taken the place of Prof. Comfort A. Adams; and representing the General Electric Company, Dr. Elihu Thompson and Mr. Magnus W. Alexander. In addition, Prof. W. H. Timbie of the Institute was selected to work in close and almost daily contact with Mr. Charles K. Tripp, the official in charge of the educational courses at the Lynn Works, in supervising the progress of the students and looking after all necessary administrative details, including the proper housing of the students and the conduct of certain lecture courses each week for the students on assignment at the Lynn Works.

As stated before, the coöperative engineering course covers a total of five years, the first two being identical with the freshman and sophomore years at the Institute and the last three being divided between instruction in theory at the Institute and instruction in practice at the Lynn Works. In these last three years the total time occupied in studies at the Institute and practice at the Works is eleven months per year, so that the students are provided with one month of vacation each year. In a general way, in the first four years of the coöperative course, the Institute covers instruction similar in method and content to the usual four-year engineering course, with certain omissions and abridgments for which equivalents are provided at the Lynn Works. During the final or fifth year of the coöperative course, however, the Institute gives advanced or post-graduate instruction in research and creative design. On the other hand, the training at the Lynn Works is laid out and conducted with a primary view to its educational value and is closely correlated with the instruction at the Institute; with it all, however, the instruction is eminently practical in character and is on the surface as little as possible differentiated from the regular work of the General Electric Company. In this way the coöperative students not only perform work as it is performed by and demanded of a commercial industrial establishment of recognized standing, but they perform it under the same conditions and in connection with the same types of co-workers, high and low in rank, as those with whom they will be associated in their daily work when they will have finally taken their places as engineers and managers in industry.

Juniors from the Massachusetts Institute of Technology, or students from any other engineering school who are eligible as juniors at the Institute, may enter upon the coöperative engineering course if they are also acceptable to the supervising official at the Lynn Works, and they may continue in the course as long as their work and deportment are satisfactory to both institutions. If a student should at any time during the course so fail to satisfy either institution as to make his separation from either advisable, he is automatically dropped by both from the coöperative engineering course—without any prejudice, however, as to his continuance in other employment at the Institute or at the Works.

thirteen weeks, is spent at the Works by all of the students during the summer period immediately following the sophomore year at the Institute. The succeeding terms of similar duration are spent alternately by each half of the student group at the Institute and at the Works, while the final term is spent by all the students at the Institute for additional advanced instruction and the preparation of a master's thesis prior to the college commencement. An opportunity for an additional optional summer term of engineering and research assignments at the Works will be open to those graduates of the coöperative engineering course who desire to elect it.

This arrangement offers several advantages. It gives to the Works an opportunity during the initial shop assignment to test all students as to their adaptability to practical work and for their general character; and allows rejected students or those who may then voluntarily withdraw from the coöperative course to enter the regular junior class at the Institute at the proper time. At the other end of the course it brings both groups of students together for nine weeks of intense application to original research and to thesis work, and permits of the formation of closer college associations and the development of a broader college spirit. Thus, each coöperative student class commences and finishes the course at the same time for all members.

On the other hand, the division of the intervening time of substantially two and one-half years of coöperative training into periods of thirteen-weeks' duration enables the students to complete one or two assignments at the Works within each period and to fit into the standard classes at the Institute. The advantages from a pedagogical, practical, and economical point of view are obvious. Each thirteen-weeks' period assigned to the Institute comprises eleven weeks of classroom attendance and two weeks of vacation, thus giving each student a vacation of two weeks twice each year. These vacations are not so much for recreational purposes—for the complete change in character of work after each period provides in itself recreation—but more for the sake of gradual change of emphasis from taxing mental work without physical strain to that of essentially physical effort for the achievement of an intellectual purpose. The robust health of the coöperative students and their marked mental agility while at the Institute furnish corroborating evidence of the wisdom of the plan.

In order, however, to keep the mind active during the assignment at the Works so as to avoid, as far as possible, the necessity of taking up a slack at the beginning of the Institute periods, all coöperative students are required to attend lecture courses and to do a certain amount of scholastic work while at the Works. To this end members of the Institute faculty are devoting certain evenings each week at Lynn to the teaching of electrical engineering subjects, English, and accounting, thus making the study of electrical engineering theory continuous throughout the three years of coöperative training, so arranged that theory and practice are linked with each other step by step as far as this is practicable. Similarly the continued study of English has for its main purpose the training of the potential engineers in effective speaking and writing, and the enlarging of their interest in human activities generally, while the addition of instruction in accounting is for the purpose of emphasizing the importance of considering time and cost, and for giving familiarity with the statistical methods of keeping record of the same. The coöperative students, while at the Works, are also expected to devote part of their evenings and Saturday afternoons to selected reading collateral to their scholastic training.

In addition, the managers and superintendents in charge of various departments at the Lynn Works give weekly lectures on different phases of manufacturing methods and business practices. The students are therefore obtaining first-hand engineering and business information of an eminently practical character and are brought into personal contact with the leading officials at the Works. It is obvious that this system of study and lecture service, combined with the weekly practical work schedule, contributes not only to the students' technical knowledge and literary appreciation, but also keeps them in a mentally alert condition. This, in turn, reflects itself, as experience has shown, in the wide-awake attitude of these students when they return to the Institute for their college an observed effect.

Briefly outlined, the curriculum of the coöperative engineering course comprises substantially thirteen weeks of machine-shop training, assembling and inspecting; five weeks of practical work in winding and insulating electrical elements of machinery and apparatus; thirteen weeks of drafting and designing experience; twenty-one weeks of testing of meters, motors, generators, transformers and steam turbines, and twenty-six weeks of practical engineering and research assignments in the various engineering departments of the Works.

On the side of the Institute work the curriculum provides for the usual program of regular junior and senior classes in the Institute's engineering departments, minus certain parts of the standard curriculum which can more effectively be taken care of at the Works, such as drafting and designing, testing and calibrating, and some of the engineering laboratory work. On the other hand, during the last Institute assignment of nine weeks coöperative students are given training in business law and organization and, as already stated, are afforded the necessary time and facilities for their master's-degree thesis.

The study and lecture system, linked up with the practical work while the students are at the Lynn Works, is facilitated greatly by the arrangement under which coöperative students are given opportunity, even though they are not obliged, to live at a well-situated club house at Lynn. This club house is now given over entirely to the use of coöperative students. It provides adequate facilities for lecture and study purposes. A similar residence is provided for the students while at the Institute, thereby facilitating the interchange of residence between the two locations.

During their assignments at the Lynn Works students are subject to the usual rules and regulations applying to employees of the General Electric Company, including a reasonable physical examination by the company's Works physician. The periods of rather strict discipline at the Works are a happy offset to the alternating periods of greater freedom at the Institute, save for the observance of regular college discipline during lecture courses and laboratory assignments. In addition, because now living under the discipline that a commercial establishment must exact of its working force, the coöperative students will, when they have been graduated into managers and leaders of men, be in a better position to prescribe and enforce discipline of others with wisdom and discretion.

Compensation is paid to coöperative students during their assignments at the Works. On a full week's regular work schedule this compensation amounts now to $21 per week at the beginning and $24 per week at the end of the course, these rates having been increased by $6 and $4, respectively, from the rates originally established.

The coöperative class which started in the summer of 1919 numbered 28, of whom 27 are still in the course preparing to enter the third and last year of the coöperative training within a few weeks. The class which entered in the summer of 1920 numbered 54, of whom all are still pursuing the coöperative training. It is the intention to start a third class this coming July, and there seems to be no doubt in the minds of the supervising committee and the officials of the two interested institutions that an entering class of from 40 to 60 students will be selected and provided for each coming year, so as to continue the flow of students through the course.

As stated before, the Institute faculty is heartily approving the coöperative engineering course. The officials of the General Electric Company are equally convinced of the efficacy of the plan. What is more significant, however, is that the superintendents and foremen, and even section leaders and individual workmen, are cheerfully doing their part to help the coöperative students in their work. The supervisory committee believe that this experiment in coöperative engineering training will exert a most beneficial influence upon the relationship of the engineering college to industry, and upon the activities of each. All parties, however, are clear in their own minds that the coöperative training in engineering must not and cannot replace the regular engineering courses at colleges which in the nature of things must cater to the majority of young

The Rise of the Industrial Worker in an Organized Society[1]

By IRA N. HOLLIS,[2] WORCESTER, MASS.

MANY volumes wouldbe required to deal adequately with the great industrial upheaval that has taken place since James Watt applied the steam engine to a rotating shaft in 1781. The information at the present time is meager and statistics are almost valueless. It will be reserved for some future historian to write about the rise of the industrial worker after he had either emerged from this period of doubt and conflict or pushed upward into the control of society. We can see evidences of change and we can understand well what is meant by industrial warfare, a warfare that would have involved much bloodshed a few centuries ago, but happily now, through our conception of democracy, is taking place without bloodshed and in most cases without evil memories and evil deeds. We can only hope here to indicate the size of the problem ahead of society in this twentieth century.

A short paragraph in Daniel Webster's speech against Hayne expresses fairly accurately our position today:

> . . . When the mariner has been tossed for many days in thick weather and on an unknown sea, he naturally avails himself of the first pause in the storm, the earliest glance of the sun, to take his latitude and ascertain how far the elements have driven him from his true course. Let us imitate this prudence and before we float farther, refer to the point from which we departed that we may at least be able to conjecture where we now are.

He might also have added,"to determine the course that we had been following since the last observation of the sun was taken." Our country is in the troubled sea and the clouds have completely cut off the sun, so that we truly are in the position of the puzzled mariner who knows neither his course nor his place on the ocean.

Who are the industrial workers of America? As a matter of fact we all are, except a few who by inheritance are freed from the anxiety of the shifting industries. The man who receives a large salary usually works harder than the man who receives a small salary, and in addition has to stand the constant wear of responsibility. Why should a distinction be drawn between wages and salaries? It does not make much difference whether a man is paid by the hour, the day, the week, the month, or the year; he must always have some employer to please. The common laborer is more fortunate than the professional man in that he usually has only one employer, while the professional man has many, and he draws his pay only in proportion to his service. The piece worker and the professional worker are on exactly the same level and obtain their wages by practically the same method, the only difference being the character of the work.

Too much has been said about capitalistic government. Capital usually represents the hard-earned wealth of those who were frugal and careful. It is true that there are some who have taken advantage of the development of recently discovered raw materials or resources or inventions, but in the main, all the people in the United States are capitalists. In many cases the workmen themselves who have been foresighted have accumulated some capital, and in most cases an industry in the United States represents the effort of some one who began at the bottom.

We know also the enormous expansion of invention made possible through the application of mechanical energy. This has been largely material and there is no evidence whatever that man has advanced either morally or ethically since the Constitution of the United States was written.

We are trying out a social evolution on a great scale which can be tested only through the lapse of many years and the complete readjustment of society to the new forces in our hands. In this change one class cannot be considered as separated entirely from another, and when we speak of the rise of the industrial worker we must at the same time consider his relation to others.

[1]Abstract of address delivered March 25, 1921, at a joint meeting of the New York Section of the American Institute of Electrical Engineers and the Metropolitan Section of The American Society of Mechanical Engineers.

[2]President, Worcester Polytechnic Institute. Past-President Am.Soc. M.E.

We may study this subject under five general heads:

1 The increase in numbers of the industrial workers
2 Their gain in power through combination
3 Their wealth
4 The opportunities for advancement
5 The satisfactions in life derived from their occupations.

It is upon the latter that I really prefer to dwell; as after all the success of any great change is measured by its permanent influence over the happiness and the mental attitude of society toward life.

Increase in Numbers of Workers

There has without doubt been an increase in the number of industrial workers since our Civil War, but the relative increase is largely a matter of definition. The term "industrial worker" has come to mean something quite different from the domestic workers of the eighteenth century, and consequently it is hard to make a comparison even between years so short a distance apart. The increase of labor-saving machinery would, if the only influence, reduce the number of workers and turn them to agriculture or other avenues, but with invention there has come more than a corresponding increase in the standard of living and the demands for manufactured articles, increasing the number of workers. In the automobile industry alone we have now nine million workers as against none in 1861.

Gain in Power Through Combination

It is evident that the power through organization of a minority has increased enormously. In some respects this has benefited all labor. In other respects it is a threat, because it is the strength of minority in a government which has as its ideals the predominance of the majority.

The power of the unorganized industrial worker has been found in the vote of quiet citizens who do not follow radical leaders and who have not felt the need of pressure by a central organization to better their conditions.

The power of organization stands out plainly, as we have at present the ruling of this country, at least in part, by minorities. That is what invention has done for us. By the use of labor-saving machinery and the change from the old type of mechanic to the specialist, we have built up enormous aggregations of capital and of labor. Wherever these exist, monopoly is possible, and control by the minority is also likely.

One of the directions in which the power of labor organization has been felt is in the reduction of hours. That has followed naturally upon the use of mechanical energy, and every individual in the United States is entitled to his share of the gain that has followed from putting our work into the hands of machine slaves. While it is not necessary to go into details of calculation, the potential power of America is between three and four thousand million men. That is based upon mechanical energy and all other forms outside of the human body. It follows at once that every inhabitant inherits the benefit of between thirty and forty manpower, or, as I have called it, thirty and forty "machine slaves." We, as citizens of the republic, are determined that this benefit shall not be obtained by a few, hence the difficult period through which we are passing. The hours of labor ought to have been reduced, and it is possible that with increasing invention they can be reduced still more.

In summing up this matter of power and the rise in power, it may be said that there are two methods by which this power may be exerted:

1 The quiet vote of the great majority of workmen who are following the constitutional system of representative government without pledging themselves first to fealty toward a union or an organization;

2 The organization of a minority for united action, either by holding the balance of power or by controlling through actual force certain agencies of our Government.

Wealth of the Workers

The gain in wealth of any community or state is measured by the conditions of life, and usually it is quite impossible to separate one class from another. Has labor made any substantial gain? It is doubtful if the average individual in labor is better off today than he was sixty years ago in the sense of being contented, but it is probable that a vastly larger number of laboring people are comparatively well off. The fact is that America has never had any of the great poverty that existed in Europe because we came to a country which God had endowed with boundless resources not yet used by man.

A fair measure of gain may be perhaps afforded by the savings banks. Are the deposits greater than they were sixty years ago in proportion to the population? Without question they are. Many places where there is large manufacture have shown enormous gains. We may conclude, though, that labor has risen in wealth during the past century simply because the standard of living is vastly in advance of anything our ancestors could have imagined.

Opportunity for Advancement

After all, we get down to real values as we leave the numbers, the power, and the wealth of the industrial workers. The most important thing in this life is opportunity.

The machinery of mechanical energy has opened the way to undreamed-of achievement, and every individual should find it possible by his work to do better for himself than ever before in the history of the world. In our experience it is true that a man may rise out of the ranks more readily than ever before. Opportunity is better than ever before. That is a true measure of the rise and the kind of advance which carries civilization along with it. I know of no more interesting history than that of the industrial communities in the United States. In one of them where I live, almost every factory is founded on the energy, enterprise, and character of workmen who sprang up among us. When we talk of the closed shop as a means of shutting out non-union labor, we are simply taking a step backward and absolutely laying a barrage through which individual enterprise cannot pass. One of the things that labor should not forget is that many of the men against whom they are endeavoring to legislate, as the managers or the capitalists, have been like themselves ordinary workmen who have taken advantage of the opportunities afforded through this democracy.

The curse of our modern controversy on the subject of capitalism or capitalistic government springs out of a total misunderstanding of what opportunity means. When the present governing classes in Russia speak of the bourgeois with a certain amount of contempt, they refer to the people whose families made Russia. Are we drifting backward here toward that form of government or are we going ahead in developing opportunities and openings for men to rise out of the ranks? No statistics can tell that. It is impossible to answer the question satisfactorily, but we do know that when the time comes that a man's right to make a living shall be judged solely by his membership in an association, in a church, in a political party or otherwise, then our Government is in danger.

The gathering power of labor may be summed up through the disappearance of monopoly. In the decision as to conditions under which labor has to be carried out, the disappearance of political democracy as the prime essential of government and the appearance of an industrial consciousness will do more than make this world safe for democracy. It will adapt democracy to work a new form of government which the twentieth century must work out, and in which the engineer must have a voice in order that the test of opportunity may become a reality instead of a shadow upon the first page of our own national Constitution.

Satisfaction from Occupation

We are certain of one thing, and that is that no citizens can take any satisfaction or feel happy with the present condition of warfare in the United States. The "get together" spirit is passing even from the churches, although there is some indication that certain sects are prepared to coöperate. There has never been a time of greater restlessness or discontent in the whole world. The United States is feeling the effect of it, but on the other hand there has never been a time of greater responsibility for the human race. It is perfectly proper, then, to inquire in this connection what are the satisfactions of life and what effect are they going to have on the happiness or the continuance of the race? What are they going to do for the industrial worker? Through them is he going to have a true rise and influence over the future of our Government, or is he simply going to sink to the level of the poor, struggling mortals of an outworn century? I have put the whole thing down in a formula that no one can be satisfied unless he has served, and he can serve only through work.

I ran across some sentences in Spencer's Ethics a few days ago, and one of these I put down here as written when Spencer was a young man. I omit a large part of the paragraph and take only the words that apply to the subject under discussion: "The growth of voluntary coöperation has been necessarily accompanied by decrease of aggression and by an increase of sympathy leading to services beyond agreement." Could anything define better what should be the true rise of the industrial worker? "Services beyond agreement;" where do we find them today, through the labor organizations or through the employers? In this advancing power of the industrial organization more attention has been paid to control than to service. Little has been done to better the lot of working men and women in the nature of the higher satisfaction that follows through better preparation for service. The tendency has been quite the other way.

The rise of any human effort or agency is measured by its tendency to minister to the satisfactions of life. No gain in numbers, power, or wealth that does not accomplish this is a permanent gain. It must pass away.

REQUIREMENTS OF THE ENGINEERING INDUSTRIES AND THE EDUCATION OF THE ENGINEER

(Continued from page 395)

men seeking a thorough training in the engineering sciences, and many of whom do not enter the manufacturing industries. The coöperative engineering training, however, is destined to become a vital integral part of a comprehensive system of engineering education, to the detriment of none of the other parts, but to the mutual benefit of all, and is particularly important to the manufacturing industries of the nation.

The pragmatic test, of course, will come for this plan, when the first group of coöperative engineering students will have been graduated and will have taken their rightful place in industry. It will then be seen to what extent these graduates will more quickly fit themselves into and become effective leaders of that branch of industry which calls for practical engineers accustomed to applying the technical sciences to the needs and wants of the human race, equipped by their understanding of human nature to coördinate human forces and to inspire them with their leadership, and endowed with that vision which will permit American engineering industries to develop to the greatest benefit of all engaged therein and to the glory of our country.

The project is planned to afford a definite professional education of a high order leading toward the technical and executive responsibilities in industry. In order that this ideal shall be accomplished, several factors must contribute to the desired end. The engineering college should have a notable capacity for teaching the exact sciences, and also sympathize with coöperation by means of which its students may obtain coördinated experience and instruction in practical employment. The officers and department heads of the industries participating in the coöperative arrangement must also correctly appraise the advantage to leadership in industrial engineering of a rational scientific as well as a practical training. Given these relations and a readiness to enter into mutual supervision of the enterprise, a foundation for success is laid.

The Failure of Metals Under Internal and Prolonged Stress

AT A JOINT MEETING of the Faraday Society, the Institution of Mechanical Engineers, the Iron and Steel Institute, the Institute of Metals, the North-East Coast Institution of Engineers and Shipbuilders, the West of Scotland Iron and Steel Institute, and the Institution of Engineers and Shipbuilders in Scotland, held in London on April 6, the subject of failure of metals under internal and prolonged stress was discussed.

In an introductory address, Dr. W. Rosenhain surveyed the nature of the problems before the meeting and their actual position. He related some experiments he had performed to investigate the time element in tension testing, and ascribed season cracking to viscous flow in the amorphous intercrystalline layer found in metals. An aluminum alloy having a tensile strength of 24 tons per sq. in. ruptured under that load in 2 min., but supported loads of 16 tons, 14 tons and 13 tons per sq. in. for 9 min., 31 min., and 56 min., respectively. This time effect, however, was only associated with intercrystalline fracture. Dr. Rosenhain projected on the screen photomicrographs which, he believed, confirmed the hypothesis explaining season cracking by viscous flow. His slides showed that crystals with smooth regular boundaries were easily cracked, and that when the same material was treated so as to make the boundaries irregular it would not undergo intercrystalline cracking under any circumstances. In confirmation of his argument, Dr. Rosenhain pointed out that ordinary wires would, if twisted, not quite reacquire their original position when released; but if the wire consisted of a single crystal the return was immediate and complete, because then there was no seat for viscous phenomena in any intercrystalline boundary. In his final remarks the speaker referred to the opinion of metallurgists who explain intercrystalline cracking as a result of chemical action. He experimented with metal strips which were annealed in different media, some in air, moist or dry, some in hydrogen, and some in vacuo. Season cracking occurred in all although much sooner in those treated in air than in those treated in vacuo or in hydrogen. This, he said, proved that season cracking took place in the absence of chemical action.

Fourteen technical papers were presented, of which excerpts from seven are given below. (Others will be abstracted later in this section if space proves to be available.)

CHEMICAL INFLUENCES IN THE FAILURE OF METALS UNDER STRESS

By Cecil H. Desch

There are two directions in which the failure of metals under stress may be influenced by chemical conditions, the first being through the composition of the metal or alloy, and the second through contact with a substance which is capable of reacting chemically with the metal. The first of these has not been systematically investigated. The form of failure known as "season cracking" appears to be confined to a limited class of alloys, principally brasses and alloys of copper with zinc and nickel. In the brasses the liability to crack under continued stress appears to increase with increasing zinc content and to be favored by the introduction of iron or tin. On the other hand, intercrystalline failure under the application of stress may take place in many other metals, including steel, in such circumstances as to indicate a relation to season cracking. Brasses composed of the better constituent occasionally crack in the cast condition, without the application of external stress, and this form of failure is always associated with the presence of aluminum in the brass. The influence of corroding agents has been rather more fully studied. The most striking feature of this action is its specific character. In the case of severely cold-worked metals in a state of internal stress, cracking may be produced by contact with solutions of mercury salts or with ammonia, but only rarely by any other reagent, although acids may attack the metal much more rapidly than either of these. The difference between reagents in this respect does not appear to be merely one of degree, but the strictly selective action of certain compounds is very remarkable. Chemical action in metals frequently advances along the surfaces which separate the crystal grains more rapidly than through the mass of the metal, and such a course is more likely to occur when the portion of the metal which is exposed to the reagent is in a state of tension than when it is in compression or in an unstressed condition. At the same time, this process is not observed with all reagents. The action of strong acids is so powerful that the minor differences between the crystal boundaries are obliterated, but their mode of action may be intercrystalline when the metal attacked is in a highly cold-worked condition. The action of weak electrolytes is usually intercrystalline. Mercury is the most powerful reagent for separating the crystal grains at the ordinary temperature. Tin and other fusible metals behave like mercury at higher temperatures. None of these reagents, however, can produce an intercrystalline weakness which does not previously exist, but only reveals, either a state of stress, as in the cold-worked metals which are subject to season cracking, or a state of weakness of unknown origin, as in some large castings of propeller alloys. (*Engineering*, vol. 111, no. 2884, April 8, 1921, p. 418, *g*)

INTERCRYSTALLINE FRACTURE IN STEEL

By D. Hanson

A description of four cases in which steel developed intercrystalline cracking, and a consideration of the general causes of season cracking. The first case was that of a steel wrapper plate from the combustion chamber of a marine boiler, which was severely cracked around the edges between the rivet holes. The chemical composition of the plate was not unusual, although the phosphorus content was 0.7 per cent. Tensile tests gave normal results for the center portions of the plate, but the edges showed a low elastic limit and elongation, while notched-bar impact tests gave variable and low results. Microscopic examination revealed the fact that the cementite occurred mainly in the form of intercrystalline films. The second case was drawn from the drum of a water-tube boiler, and the cracks as before started mainly from the edges of the rivet holes, though some were found to start at the calked edge of the plate. Microscopic examination showed the existence of intercrystalline films of cementite. The third case was found in a number of plates from a high-pressure marine boiler. In this case intercrystalline cracks were found in the steel at a point where the thickness of metal was 4 in., including the wrapper plate of the boiler, two butt straps and a cover plate. Failure is attributed in these three cases to the probable existence of internal stresses in the material. Another case of intercrystalline failure, in which internal stresses appeared to have been present in the metal, was that of a piece of cold-drawn steel tubing which cracked after six months intermittent service without working stresses in a niter bath operating at a temperature of 300 deg. cent. The cracking in this instance was probably accelerated by the corrosive acting of the fused nitrate at the working temperature. It was observed, however, that as similar steel tube which had been annealed below the critic range, and another which had been normalized, did not crack when exposed to the action of the fused salt. The evidence afforded by the instances mentioned is adduced in support of the theory that internal stresses are the main factor in bringing about failures in season cracking. It is believed that the most favorable conditions for the development of the phenomenon in the case of steel arise within a temperature range a little below 300 deg. cent. corrosion is considered as an after effect and not the primary cause of cracking. Failure can occur solely as the result of stresses either internal or external, to which the metal is subjected. (*Engineering*, vol. 111, no. 2885, April 15, 1921, pp. 467–469, 7 figs., *d*)

THE MECHANISM OF FAILURE OF METALS FROM INTERNAL STRESS

By W. H. Hatfield

A study of the influence of cold work and of chemical action on the failure of metals without the operation of deforming stresses. The possibility of the existence of the non-crystalline phase of metal either between the crystals or as a result of cold work, at temperatures ranging from the freezing point to the normal, has been postulated as a general working theory to explain such phenomena as season cracking in brass, smashing of castings from internal stress, the rupture of ingots, of hardened steel parts, etc. This theory is examined in the light of experimentally established facts. No direct evidence is found of the existence of an amorphous condition in metals. Arguing, however, from the results obtained in experiments on cold-worked and annealed brass, it is established that the amorphous phase, as compared with the crystalline, is considerably harder, and has a higher elastic range and a reduced capacity for plastic deformation. It is also experimentally determined that the amorphous phase cannot have sufficient mobility to allow viscous flow. The general conclusion is that except in certain cases where selective chemical or physico-chemical action causes a separation of the remains of crystals from each other, fractures such as those under discussion are due to internal stresses introduced during processes of manufacture. Such stresses may not be high enough, initially, to produce rupture, but rupture occurs when weaknesses introduced by chemical or other influences lead to increased local concentration of stress, or in some cases where changes in temperature in themselves lead to accentuation of the breaking stress. (*Engineering*, vol. 111, no. 2884, April 8, 1921, p. 435, *e*)

INTERNAL STRESSES IN RELATION TO MICROSTRUCTURE

By J. C. W. Humfrey

Study of the microstructure of metals and of the mechanism of their behavior under plastic deformation indicates that internal stresses between one crystal and another, due to a previous overstrain or thermal treatment, must play a large part in determining the subsequent mechanical properties. It is found that if a metal is overstrained in tension and allowed to "recover" its elasticity, then, in addition to the elastic limit in tension being raised, the corresponding elastic limit in compression is lowered; vice versa, if the elastic limit in compression is raised by overstrain in compression, then, at the same time, the elastic limit in tension is lowered. The two elastic limits appear in fact always to move in the same absolute direction together, metals possessing a certain elastic range, which, while it may vary in extent, yet reaches certain limiting values. In a bar built up of two materials possessing different mechanical properties, uniform straining will set up internal stresses which have the effect of producing a symmetry in the position of the elastic limits, similar to that which has been found in the actual experiments upon metals. It would appear reasonable, therefore, to deduce that the heterogeneous structure of metals was responsible for this particular phenomenon. In pure metals it is considered that the intercrystalline boundaries are the chief cause of heterogeneity of structure. Microscopic study of the effects of strain shows that the boundaries offer a definite barrier to the propagation of continuous slip between two crystals, and that each crystal in a mass of metal behaves as if it were enclosed in a thin but hard skin which can only deform by elastic bending. In alloys, and especially in the carbon steels, the heterogeneity is more evident, and it is obvious that no general deformation can take place without comparatively large stresses being left between the different crystals. A photomicrograph of severely strained pearlite shows that the cementite laminæ lying in the direction of the strain have been doubled up into wave forms. Internal stresses can also be set up in metals by virtue of the possession by the constituent parts of different coefficients of the thermal expansion. In steel, the coefficient of the ferrite is 10 per cent less than that of the pearlite, which might result in the ferrite being put into compression. (*Engineering*, vol. 111, no. 2884, April 8, 1921, pp. 419–420, 3 figs., *t*)

INTERNAL FRACTURES IN STEEL RAILS

By Henry S. Rawdon

A discussion of the type of defect known as "transverse fissure," which is sometimes found in the heads of American steel rails. Its prevalence in American rails is attributed to the difference in the service the rails have to withstand and the harder rail which is used as compared with European practice. The defect is internal and consists of a bright silvery mass enclosed within the normal metal and itself enclosing a nucleus of coarsely granular appearance. The microscope reveals a number of deep gashes or discontinuities, usually, though not always, approximately perpendicular to the axis of the head of the rail. These internal cracks have been found in rails before use, but are much more frequent in rails which have been in service. The general opinion is that transverse fissures represent the growth of internal defects which arise in the rail as a result of the severe cold-working of the tread and become larger and larger with the repetitions of stress developed in the rail in service. The fact that the appearance of the nucleus is identical with that of the face of internal fractures also strongly supports the view that the two are one and the same thing. This is in line with the well-known fact that fatigue breaks of all kinds originate most readily in the neighborhood of those defects which considerably modify the stress distribution. (*Engineering*, vol. 111, no. 2885, April 15, 1921, pp. 470–471, 2 figs., *g*)

INTERNAL STRESSES IN BRASS TUBES

By R. H. N. Vaudrey and W. E. Ballard

An investigation of a peculiar type of failure in some brass tubes of circular section containing 70 per cent of copper. The defect took the form of an apparent stratification of the wall of the tube, which was shown by the ordinary commercial test of expanding on a conical plug. The fracture usually showed at least two layers, the outer one being dark and tarnished, the inner one crystalline. "Hollow-sunk" tubes were first studied, that is, tubes drawn through a die without any form of internal support. A tube $1^3/_4$ in. in external diameter and $1^1/_2$ in. in internal diameter was annealed and hollow-sunk to an outside diameter of $1^{29}/_{64}$ in. A piece of the tube about 3 ft. 6 in. long was left on a table for four days and at the end of this period it had deformed 1/4 in. from the straight. Lengths of 2 in. of the tube, with multiples of 1/64 in. turned off the inside and outside, were immersed in an acid solution of mercurous nitrate and the times taken for the specimens to crack noted. Similar experiments were conducted on a tube drawn from the same original size, through a die of $1^{23}/_{64}$ in. bore, the inside being supported by a $1^1/_8$-in. diameter mandrel bar. It was concluded that in the "hollow-sunk" tube a thin layer on the outside of the wall was under high tension rapidly falling to zero, while a thin layer on the inside was under a high compression. In tubes manufactured without sink the internal stress passed uniformly from a maximum tension on the outside through zero to a maximum compression on the inside. The stratification of the specimens which occasioned the investigation was attributed to the tubes having been formed with too large a sink and too small a reduction in thickness, combined with the cracking action of the pickle bath. (*Engineering*, vol. 111, no. 2884, April 8, 1921, p. 421, 5 figs., *e*)

NOTES ON FRACTURES IN LOCOMOTIVE BOILER TUBES

By Sir Henry Fowler

A study of a peculiar brittleness that was found to have developed in the superheater tubes of a locomotive after it had run about 60,000 miles. Investigation showed that of the 21 large tubes, 8 had brittle ends, while 13 were fairly malleable. The tubes were lap-welded, and it was obvious that the steel-tube strip from which they were made was in both cases of poor quality. Microscopic examination showed that the impurities were largely concentrated in the boundaries between the crystals, and that the fractures were generally intercrystalline. The actual increase in the diameter of the tubes due to expansion was found to be only about 3.5 per cent of their original size. Tensile tests taken from the ends and middle

of the tubes disclosed the fact that in both the brittle and the malleable specimens the maximum stress was much greater and the elongation much less at the ends than at the middle. In bending tests the expanded portion of a brittle tube fractured at 10 deg., while pieces beyond the zone on which work had been put passed through an angle of 180 deg. without fracture. In some few cases the fractures showed laminated materials and signs of rust. In order to ascertain if the brittleness of the tubes was due to the original stresses set up in expanding, portions of two separate brittle tubes were taken from unaffected parts of the tube, made into rings and expanded in the usual way. The Brinell hardness was in one case increased from 111 to 156, and in the other from 131 to 143, but in neither case did the metal become brittle. No definite suggestion as to the causes of the brittleness and fractures is offered, but it is intimated that they might be due to the repeated stresses set up during the work of the locomotive acting on the material already in a state of stress, regard being had for the fact that the phosphorus content of the metal was 0.009 per cent. (*Engineering*, vol. 111, no. 2885, April 15, 1921, pp. 466–467, 11 figs., *e*)

Short Abstracts of the Month

AERONAUTICS

Aircraft Statistics. The following preliminary statement of the general results of the 1920 census of manufactures with reference to aircraft has been issued by the Bureau of Census, Department of Commerce, and furnishes a detailed statement of the quantities and values of the different types of aircraft manufactured during the year 1919. It was prepared under the direction of Mr. Eugene F. Hartley, Chief Statistician for Manufactures.

Reports were received from 31 establishments engaged in the industry during 1919 showing products for the year valued at $14,372,643, as compared with 16 establishments in 1914 with products valued at $789,872. Of the 31 establishments reporting for the year 1919, ten were in New York; four in Ohio; two each in California, Massachusetts, and Missouri; and one each in Connecticut, Indiana, Illinois, Louisiana, Maryland, Nebraska, New Jersey, Pennsylvania, Rhode Island, Washington, and West Virginia.

The following is a summary of statistics of the industry for 1919, the "All other products" reports consisting chiefly of airplane parts, engines, and repair work:

Number of establishments	31
Total value of products	$14,3⁻2,643
Airplanes:	
Number	432
Value	$3,466,452
Seaplanes:	
Number	230
Value	$4,580,016
Value of work done during year on airplanes and seaplanes not completed	$1,658,670
All other products, including parts and repair work	$4,667,505

(*Department of Commerce, Bureau of Census, Preliminary Notice.*)

Strutless-Type Aeroplanes, E. Meyer. Discussion of the elementary theory involved and description of some European types of strutless planes.

The main reason for the existence of the strutless plane lies in the desire to reduce the so-called parasite resistances, i.e., resistances to the motion of the plane which do not in any way contribute to its lift. Such resistances increase very rapidly with increase of speed, and call for correspondingly greater expenditures of power.

Of the planes described the Junkers is well known in this country. Of the other planes may be mentioned the Siemens-Schuckert monoplane, the Fokker monoplane, the Sablatnig machine, and a very interesting monoplane hydroaeroplane of all-metal construction, built by the Zeppelin Works in Lindau and known as the Dornier. No detailed data are given as to any of these machines except the general dimensions and rated power of the engines, and in the case of the Zeppelin plane not even these are given. (*Schweizerische Bauzeitung*, vol. 77, no. 15, Apr. 9, 1921, pp. 166–168, 7 figs., *d*)

BUREAU OF STANDARDS (See Engineering Materials)

ENGINEERING MATERIALS

The Sprenger Process of Making Concrete, E. Weiss. In this process a machine is used which its inventor calls the Aero-Malaxeur. In this machine wet sand and gravel are projected through an atmosphere saturated with the binding material, which may be blown in a state of complete pulverization by some kind of a blower.

The machine essentially consists of a slightly inclined mixing drum rotatable in its bearings. In the top part of the drum there is a hopper for storing the sand and gravel, into which there is discharged at a predetermined rate water to give the materials the desired degree of moisture. At the other end of the cylinder there is a double proportioning hopper containing the binding elements, such as lime, cement, or a mixture of the two. The graduated orifices admit these materials into the cylinder in a strictly predetermined proportion and a strong blast of air coming from a blower

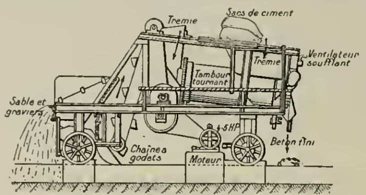

Fig. 1 Diagrammatic View of the Sprenger Aero-Malaxeur Concrete-Making Machine

Sable et graviers = Sand and gravel; *Tremie* = Hopper; *Sacs de ciment* = Cement sacks; *Tambour Tournant* = Rotating Drum; *Ventilateur soufflant* = Blower; *Beton fini* = Finished concrete, *Moteur* = Motor: *Chaine à godets* = Roller chain

carries them to meet the materials coming from the other end of the drum. As each grain of sand or gravel is projected from the upper hopper into the cylinder where it moves in an atmosphere filled with the binder, it becomes therefore completely and intimately blended with the latter.

The machine is of the continuous-operation type and is entirely automatic, the concrete arriving at the bottom of the cylinder being discharged into cars or bins. It is claimed that with this machine the lack of uniformity of sand or gravel is less important than in the production of concrete by other means. (*La Nature*, no. 2444, Feb. 5, 1921, pp. 95–96, 4 figs., *d*)

Some Properties of White-Metal Bearing Alloys at Elevated Temperatures, John R. Freeman, Jr. and R. W. Woodward. The Bureau of Standards as part of a general investigation of the properties and methods of testing the white-metal bearing alloys has developed apparatus for determining their properties at elevated temperatures. This paper describes apparatus for determining the yield point and ultimate strength of these alloys in compression at temperatures up to 150 deg. cent. A similar apparatus is also described for determining the Brinell hardness at these elevated temperatures.

The results of compression tests and Brinell hardness tests obtained with this apparatus at 25 deg. cent., 50 deg. cent., 75 deg. cent., and 100 deg. cent. are given for the five following alloys:

Alloy No	1	2	3	4	5
	Per Cent				
Copper	4.56	3.51	5.65	2.90	.....
Antimony	4.52	7.57	6.90	10.50	10.03
Tin	90.02	88.92	87.36	61.55	5.02
Lead	absent	absent	0.09	25.05	84.95
Iron	0.05	0.05	0.05	0.05	0.05

Alloys Nos. 1, 3, 4, and 5 are the four alloys being recommended by the S.A.E. as standard alloys.

The results of these tests show that the three tin-base alloys maintain their properties better at the elevated temperatures than either the lead-base or the intermediate alloys.

(*Abstract of Technologic Paper of the Bureau of Standards*, no. 188, *g*)

Influence of Nickel on Cast Iron. Buner and Piwowarsk have carried out a series of tests to determine the influence of nickel on cast iron, using Swedish charcoal iron with a total carbon content of 3.90 per cent, of which 2.80 per cent was graphitic carbon, a silicon content of 0.69 per cent, and a manganese content of 0.18 per cent. It was found that this metal readily formed an alloy with 1.2 to 3 per cent of nickel at a temperature only 50 deg. cent. higher than the melting temperature of cast iron.

Mechanical tests have shown that the best results are obtained with an alloy containing 1 per cent of nickel, the transverse strength being increased 30 per cent, the compressive strength 30 per cent, and the tensile strength 25 per cent, while the hardness is increased only 18 per cent. The addition of $1^1/_2$ per cent of nickel conferred no advantage whatever, the influence of the nickel on the separation of graphite more than counterbalancing the favorable effect on ferrite. (It is not quite clear whether by this is meant that an addition of $1^1/_2$ per cent of nickel gave no advantage as compared with an addition of 1 per cent, or that the comparison is made with nickel-free cast iron.)

For the manufacture of high-tensile cast iron for machine parts, gear blanks, etc., cast iron containing 1.2 per cent of nickel is recommended.

It is of interest to note that cobalt, which usually has an effect very similar to that of nickel, in this case acted in quite the reverse manner, reducing the resistance to bending, tensile and compression strengths, while increasing the hardness. This is due to the fact that cobalt retards the separation of the graphite and favors the formation of carbides. (*Stahl und Eisen.* Abstracted through *Automotive Industries*, vol. 44, no. 13, Mar. 31, 1921, p. 705, *e*)

Materials for Turbine Blades, P. Bardenheuer. In rolled and drawn materials for steam-turbine blades there are often stresses set up during the process of manufacture which are equalized only after the apparatus has been in use for some time. The equalization of these stresses results in permanent changes of shape and contraction of turbine parts which may more or less endanger the safety of operation of the machine.

In order to obtain reliable data as to the the magnitude of elongations in turbine blades due to the above-described causes, Gustav Wallenborn, in a thesis presented in 1916 in Darmstadt (probably at the local polytechnic institute) investigated several materials such as nickel steels, carbon steels, and the more common copper alloys, including monel metal. In the course of these tests he determined the coefficient of heat expansion and permanent elongation after tenfold heating to 350 deg. cent. (662 deg. fahr.) and also the specific weight, hardness, and tensile strength of the samples of their original state and after such heat treatment.

The test pieces were used in the form of rolled or drawn bars as well as in the final machine form of blades, the bars having either round or rectangular shapes. The cross-sections of the test pieces differed very materially. The chemical composition was not determined and exact information as to the manufacture of the test pieces before they reached the investigator was not available, which deprives the investigation of much of its scientific value.

Of the data collected the most important are presented in Table 1. Of particular interest is the expansion due to heating and the permanent elongation of the test pieces.

As regards the elongation, the author of the thesis states that it appears to depend exclusively on the molecular stresses in the material. If the material has merely been rolled, permanent elongations appear; but if it is then subjected to cold drawing, the permanent elongations gradually disappear, until after a certain number of passes a permanent contraction sets in. The correctness of this statement, however, may be questioned. (*Stahl und Eisen.*, vol. 41, no. 6, Feb. 10, 1921, p. 204, *e*)

FOUNDRY

Centrifugal Castings. Description of the methods used at the works of Stokes Castings, Ltd., Mansfield, England, where a regular output of centrifugally made castings is now being obtained, the average output for the last few months being in the neighborhood of 2000 castings per week.

The castings produced are, in the main, for internal-combustion engine work—piston-ring drums and engine liners—and it is said that perfectly satisfactory machining qualities are being obtained without any annealing or heat treatment. This result has been obtained as an outcome of an excessive series of experiments on mixtures, pouring temperatures, die temperatures, speeds, etc., each of these variants being a determining factor in the quality of the resulting material.

The quality of the product obtained is said to be markedly superior to material cast in sand molds or stationary chills. Graphite plates are practically eliminated.

The casting plant consists of a number of machines. In the latest type the machine is driven direct by means of a variable-speed motor through a flexible coupling and friction clutch. The time taken to produce a 6-in. diameter drum is something under a minute, counting from the time of pouring into the receiver on the machine to time of taking out the completed castings.

Up to the present most of the research has been devoted to the question of gray cast iron, but interesting experiments have been made with some of the non-ferrous metals. The comparison of microsections of lead-bronze castings made in ingots and centrifugally, shows that in the latter casting the grain is very much smaller, indeed about 1/150 the size of the ingot crystal. The chemical analysis of the material shows that the lead and tin have tended to fly to the outside of the casting, which is reflected in the fact that the Brinell hardness near the bore is 101 and near the outside 90.0. (*Engineering*, vol. 111, no. 2881, Mar. 18, 1921, pp. 311–312, 6 figs., *d*)

FUELS AND FIRING

Novel Type of Oscillating Grate

Two-Stage Combustion in the "Evaporator" Stepped Oscillating Grate. The stepped oscillating grate has come into prominence on the market in the last few years because of its advantages for the combustion of friable, dirty and powdery fuels. These advantages consist in the comparatively large free grate area which can be easily obtained with a stepped grate and the ease with which the dropping of fuel through the grate can be prevented. This makes the stepped grate particularly suitable for such fuels as lignite, breeze, etc.

The conditions of combustion in the case of a stepped grate are also said to favor the employment of the poor grades of fuel.

In order, however, to utilize all fuels at a higher efficiency a two-stage combustion may have to be considered, as has already been done in the new stepped grate developed by the German Evaporator Company.

Fig. 2 shows the general arrangement of the new grate. The amount of fuel supplied from a hopper on to the main stepped grate *d* is regulated by the usual gate *a*. In addition to this, there is in the hopper a throttling device *b*, the position of which can be shifted by a gear drive. The hopper *c* under the throttle *b* is equipped with airtight gates, which are used for starting the fire on

the grate and to permit seeing what is going on on the grate by withdrawing the throttle *b*.

The stepped grate itself extends into the body of the coal-supply hopper so that the mechanical introduction of fresh coal on the grate begins directly under the fuel-regulating gate *a*. This gives the coal in the hopper a slight motion and makes a constant and regular supply of coal to the grate more certain. The main grate consists of a series of perforated overlapping plates located stepwise and held by the grate-bar shoes. These latter have their bearing in the grate frame which permits a certain freedom of oscillation to the grate plates and this, in its turn, enables the spaces between the grate plates to be made smaller or greater; furthermore it permits the grate plates to be swung into a position inclined at such an angle as to sweep away the residues of the foundation fire, which is of practical importance in connection with the burning of sandy fuels, such as certain kinds of lignites. The grate-plate shoes with their lever-shaped ends, usually in groups of five, are connected to a lever with link action *e*, by means of which and the rod *f* they can be shifted into the desired position. The rod *f*, in its turn, is connected with the speed-change gear *l* driven by a motor *m*, the lever rods *g*, *h*, *i*, and *k* serving to transmit the motion from *l* to *f*. By shifting the rod *f*, the grate plates can be adjusted so as to make the interstices between them either large or small. The movement of the grate plates themselves is regulated from the speed-gear shift on the motor and must be suitably adjusted for the fuel burned, so as not to distribute the foundation fire and make certain the ignition of fresh fuel.

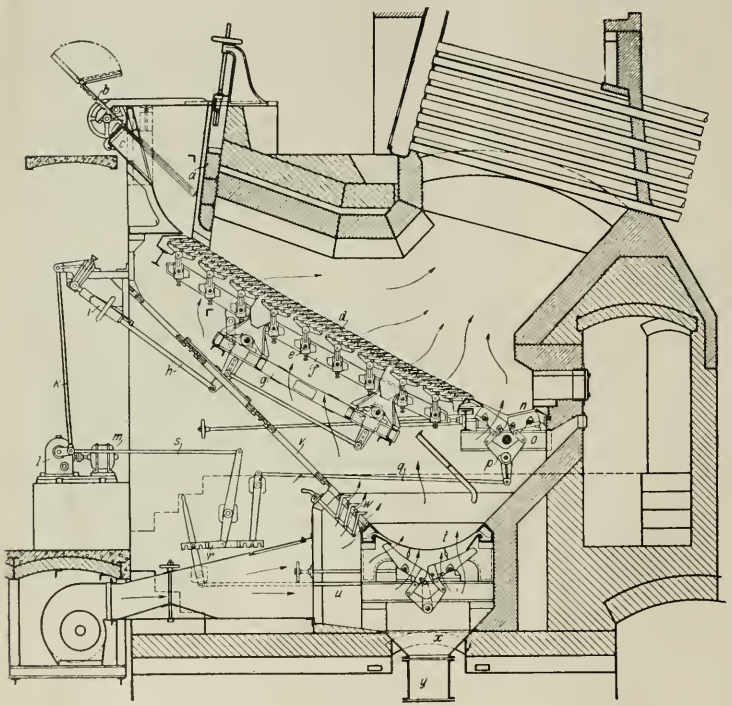

Fig. 2 Stepped Oscillating Grate with Two-Stage Combustion Built by the German Evaporator Company

The residues of combustion from the main grate *d* are taken up by the intermediary grate *n*, which acts also as a clinkering grate and as a kind of sluice for transferring the residues on to the end grate *t*. The intermediary grate consists of oscillating grate members *o* swinging in opposite directions and thereby breaking up the residues of combustion from the main grate.

From the grate *n* the residues of combustion travel down an incline to the end grate *t* which is built in the same way as the intermediary grate *n*, located in an air chamber *u* and supplied by air from a blower. This air chamber is located tight against the wall *v* of the main grate and is provided with a number of outlets *w* closed by shutters, the openings in which can be regulated. It is from this chamber that the undergrate blast is supplied to the main grate, so that the blast is partly under the main grate and partly under the end grate *t*, where it helps to burn up all the fuel residues.

It is claimed that the resulting gases of combustion together with the excess of blast highly superheated on its way, ascend upward to the main grate and materially assist in the combustion. The ashes and clinkers from the end grate go into the ash pit *x* and are discharged into the ash cars through *y*. (*Zeitschrift für Dampfkessel und Maschinenbetrieb*, vol. 43, no. 53, Dec. 31, 1920, pp. 405–407, 3 figs., *d*)

Properties and Characteristics of Colloidal Fuel, Linden W. Bates and Haylett O'Neill. It is stated that a colloidal fuel is composed of from 0 to 40 per cent of carboniferous material (coal, coke, charcoal, lignite, peat, hard pitch, or any similar grindable material) mixed with fuel oil and held in suspension with about 1 per cent of fixateur (no information given as to this latter). Data are given for determining the specific gravity and heating value of various colloidal fuels. (Paper read before the Royal Society of Arts, London. Abstracted through *Power Plant Engineering*, vol. 25, no. 7, April 1921, pp. 368–369, 2 figs., *g*)

INTERNAL-COMBUSTION ENGINES (See also Thermodynamics)

Fuel and Air Regulation in Heavy-Oil Engines

Device for Automatically Regulating the Supply of Fuel and Injection Air in Heavy-Oil Engines, Max Lindemann. With the usual Diesel-engine injection valves the conditions are such that if the air pressure and valve design are adjusted properly to take care of full-load conditions too much air is used at half load, which makes the mixture excessively lean, and if the load is reduced still further the engine may cease to fire.

This could be obviated by reducing the amount of injection air at part load, but it isdifficult to accomplish it in actual practice, because if the load varies suddenly the variation in the amount of injection air cannot follow it fast enough.

One way to obviate this is to govern the engine by varying the lift of the valve needle. By this method a practically constant composition of mixture may be maintained at all loads and the combustion conditions made more uniform and certain. This method of governing is, however, complicated and cannot be applied to all kinds of engines.

Fig. 3 illustrates a device said to have been developed by the Leobersdorf Machine Company. Here a valve disk *N* sliding on the valve stem of the fuel valve *M* is held by a spring against the lower surface of the cylindrical piece *P* fixed in the valve housing. In *P* a passage *A* reaches to the top of the piece, into which the fuel flows through another passage *T* in amounts proportional to the load. An air passage *B* is also located in *P*. The passages *A* and *B* both open into the lower face of the piece *P* and are closed off by the same automatic valve *N*.

The device operates in the following manner: The fuel introduced into the passage *A* in accordance with the load on the engine

is held therein by the valve disk N. When valve M is opened, however, N is forced away from P by the injection-air pressure, and fuel and injection air flow respectively from passages A and B. As the same constant injection pressure obtains in both passages, there is discharged from each of them an amount of fuel or air proportional to the time during which the passages are held open. Hence, once the cross-sections of the two passages have been placed in a constant relation to each other, the ratio of fuel to injection air will also have to be constant. If all of the fuel from passage A has been discharged, the remaining injection air will flow into it.

As a result of this arrangement, from the very beginning of the opening of the fuel valve a constant mixture of fuel and injection air is admitted, and this admission lasts until a sufficient amount is discharged to correspond with a given load on the engine. From then on and up to the time that the fuel valve is closed, only injection air flows into the working cylinder. Fig. 4 gives diagrammatically the proportioning of the fuel from one-quarter up to full load. In this figure the base line indicates the path of the opening of the fuel valve. The sectioned areas correspond to the injected mixture of fuel and air, while the white areas show the amount of air flowing after the flow of the fuel mixture has been cut off.

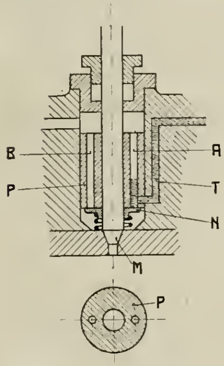

Fig. 3 Diesel-Engine Fuel-Injection Valve of the Leobersdorf Machine Co. (Germany)

In all such constructions the following two conditions must be observed:

(1) The passages for the reserve of fuel and for the injection of air must be arranged in such a manner that their cross-sectional areas which are in constant relation to each other give a constant mixture ratio of fuel and air all at loads until the entire fuel (in the reserve passage) has been used up.

(2) The passages which are closed by a common automatic valve or similar device must be so arranged that from the beginning of the flow of injection air both fuel and air are discharged; that is, from the beginning of the air-injection period a constant mixture ratio is available.

In the test carried out by the author a two-cylinder Dissel engine developing 110 hp. at 190 r.p.m. was equipped with the device shown in Fig. 5. Here a helical passage A has been provided for the fuel and from it small holes lead to the seat of the valve B. Further, six passages C are provided for the injection air in order to make it possible to vary the mixture ratio by opening and closing some of these passages.

The test engine has purposely been equipped with a very light flywheel, so that the coefficient of fluctuation has been computed to be 1/38. This was done in order to make it possible to observe the regularity and reliability of ignition from the tachogram.

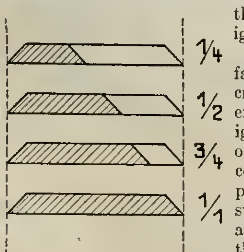

Fig. 4 Relative Fuel and Air Proportions for Various Loads with the Valve of Fig. 3

The first effort to start the motor failed. Heavy white clouds of crude-oil vapor came out of the exhaust, but the mixture did not ignite. The passages C were closed one after another by the insertion of conical rods. When two of these passages were closed the engine started to run, but it soon became apparent that the cross-sections of the air passages as compared with the cross-sections of the fuel passages were still excessive. A third air passage was then closed and the cross-section of the fuel passage enlarged by boring it out. It was only then that the correct ratio of cross-section was obtained, and the motor, even when cold and at a lower speed, began to work reliably and regularly at all injection-air pressures. The original paper shows the card covering the operation of the motor from 25 per cent overload down to no load with the injection air at 60 atmos. pressure.

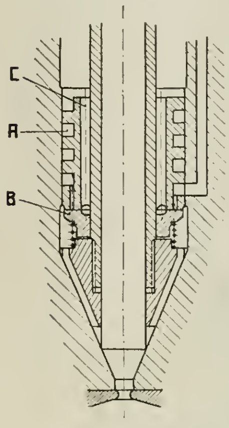

Fig. 5 Valve Used on an Experimental Two-Cylinder Diesel Engine (Same Principle as Fig. 3)

After a number of tests the motor was connected to an electric generator acting as a brake. In these tests it was found that with the full injection-air pressure the load may be varied within wide limits without bringing about failure of injection and prolonged variations in speed. It was found that the difference in pressure in the injection air between prolonged operation at normal load and prolonged operation at no load amounted to only 2 atmos. (65 down to 63 atmos.). It would appear, therefore, that the load may be varied within wide limits without any regulation on the compressor. It would further appear that the valves remain in good condition after fairly prolonged operation of the motor, (*Oel-und Gasmaschine*, vol. 18, no. 1. Jan. 1921, pp. 1–5, 13 figs., *de*)

Palm-Oil Engine Fuel. At a recent meeting of the Association for the Improvement of Colonial Materials, Major Trentals of the Belgian Colonial Army described developments in the use of palm oil and other vegetable oils grown in the Belgian Congo in internal-combustion engines.

The tests were carried out on a stationary two-cycle semi-Diesel engine developing 8 to 10 hp. at 500 r.p.m. The palm oil employed was of medium or low quality, containing considerable amounts of free fatty acids and impurities. The only really special feature on the engine was an arrangement made for keeping the palm oil in a sufficiently liquid condition. For this purpose the cylinder-cooling water was used and together with the hot exhaust gases maintained the oil in the feed tank at a temperature high enough to insure liquidity, and at the same time evaporate any water which might be present. In addition to this a gasoline vapor lamp was placed under the tank.

The feed tank consists of a series of compartments divided from each other by fine-mesh metal screens to filter the oil before admitting it to the injection pump.

The engine starts on gasoline and finishes on gasoline in order to remove any residual palm oil from the feed pipes, which might get clogged by the congelation of the oil when the engine is at rest. [The average melting point of oil is about 37 deg. cent. (99 deg. fahr.) which varies with purity and origin.]

A certain amount of water is injected into the cylinder. The palm oil referred to in this paper is obtained from the fleshy pericarp of the palm fruit and is not the palm-kernel oil contained in the palm nut. Palm-kernel oil does not differ much in heat value from peanut oil. (Paper before the Association pour le Perfectionnement du Matériel Colonial. Abstracted through *Gas and Oil Power*, vol. 16, no. 186, Mar. 3, 1921, pp. 85–86, *e*)

MACHINE PARTS (See Machine Shop)

MACHINE SHOP

Maag System of Gearing and Gear Cutting

The Maag System of Gearing. The Maag system of gearing has been developed by Max Maag, of the Maag Gear Wheel Company, Zurich, Switzerland.

The gear-cutting machine employed is a modification of the Sunderland gear planer made in England. The wheel blank in the Maag machine, however, is mounted on a vertical axis so that the cutting movement of the rack is vertical, which is said to in-

crease rigidity and enable the tool to take heavy cuts. Also, in order to eliminate the effect of the backlash in the screw communicating the rectilinear component of the rolling motion to the work, an arrangement has been introduced consisting of a second and more quickly threaded screw and nut and a friction drive, whereby the cross-slide during the generating movement is maintained in uniform contact with the flanks of the main pitch screw. The actual movement of the slide is therefore effected by the subsidiary screw, while the main screw is relieved of all duties except the regulation of the movements. It is claimed that this makes the motion truly uniform and results in a complete absence of play.

There is also an interesting arrangement for balancing the cutter ram.

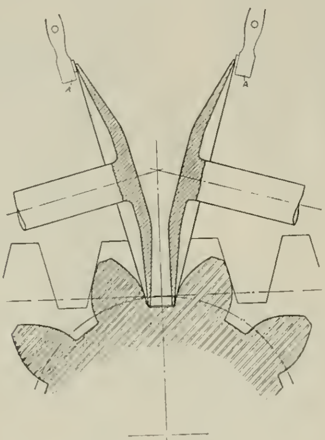

Fig. 6. Diagram Showing the Maag Method of Grinding Gear Wheels

One of the features of the Maag system is that the wheels can be formed of a mild or nickel steel and case-hardened and ground after being cut. The object of grinding the wheels is not only to produce a good surface on the hardened teeth, but to remove the distortion almost inevitably caused by the hardening process.

In the Maag generating grinding machine the grinding is performed (Fig. 6) by means of two saucer wheels set apart and inclined in such a way that the planes of the saucer lips would coincide if superimposed with the flanks of one tooth of the rack cutter used in the preceding process. The gear wheel to be ground is mounted on a longitudinal axis and is fed longitudinally beneath the rotating grinding wheels. As it passes beneath the grinding wheels the gear wheel is reciprocated transversely through a small distance and at the same time is rocked through a corresponding angle, the two movements being correlated so as exactly to reproduce the movement of the gear wheel if it were rolled, without slipping, on its pitch circle. True rack-and-pinion action is thus secured as in the preceding cutting machine, but in this case the work has to be indexed relatively to the grinding wheels once for every tooth gap, as the "rack" has but one "tooth."

The most interesting feature of the machine is the means adopted for compensating the wear of the grinding wheel which would reduce the width of tooth of the imaginary rack cutter, and therefore progressively to increase the width of the teeth being ground. The wear can, however, be compensated by moving the grinding wheels apart, each parallel with itself.

The compensating mechanism consists of an electrically controlled mechanical device. Associated with each grinding wheel is a camshaft driven continuously at about ten revolutions per minute by belt and gearing from the motor driving the grinding-wheel spindle. At each revolution the camshaft causes the lever A, Fig. 6, to oscillate on its pin and to advance, toward the grinding wheel edge, a diamond carried at its lower end. If the movement of the lever is checked by the grinding-wheel edge at the correct point nothing happens. If, however, the wear of the grinding wheel exceeds a certain amount the lever, before its movement is checked, will swing sufficiently far to establish an electrical contact. The current which then flows is relayed to operate a clutch on a continuously driven shaft from which, when the clutch is active motion is transmitted through a pawl and ratchet wheel to a differential thread and thence to an adjusting screw on the grinding spindle bracket. The bracket is thus moved until the plane of the grinding-wheel lip is restored to the correct position. The arrangement it is stated, is sufficiently sensitive to keep the wheels in the correct position to within one-thousandth of a millimeter. In addition, the compensating movement is said to be so trustworthy in action that it can be relied upon to correct the wear of the softest grinding wheel. It thus permits wheels to be used which, although they wear rapidly, are recommended from the point of view of cutting efficiency in preference to wheels of much greater hardness.

Arrangements are also made to secure the correctness of the rolling motion of the work.

An interesting gear-testing machine used by the same company is described. (*The Engineer*, vol. 131, no. 3403, Mar. 18, 1921, pp. 283–285, 5 figs., *d*. Compare *Machinery* (London), vol. 17, no. 437, Feb. 10, 1921, p. 575 *d*)

MARINE ENGINEERING (See Shipbuilding)

MOTOR-CAR ENGINEERING

Steam Car with Engine on Rear Axle

Coats Steam Car. Description of a new steam car being built at Indianapolis, Ind., and involving several apparently novel details.

In particular, the engine is located in the rear axle and the engine axle and differential function all in one, the engine itself in its housing being just about the size of the ordinary rear-axle gear case.

The housing of each half of the axle carries three fixed cylinders set at 120 deg. apart. These cylinders are exactly like those of the internal-combustion automobile engine with poppet valves, pistons and connecting rods. The bore is $2\,^3/_4$ in. and the stroke 3 in. The three connecting rods in each half of the axle are pivoted to a

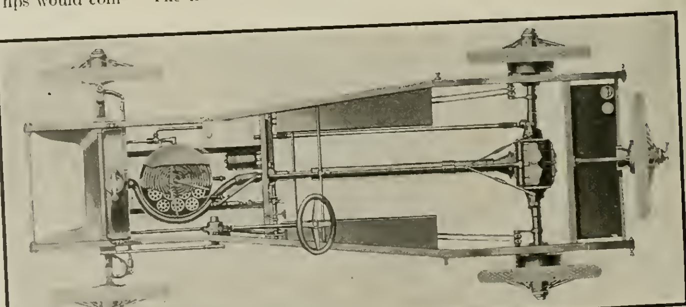

Fig. 7 General Arrangement of Coats Steam Car

crankpin integral with the drive shaft of each wheel. At a speed of 40 m.p.h. the engine is running at about 500 r.p.m.

The exhaust steam is taken by return pipe to the condense located in front of the boiler in the position of the ordinary radiator

The whole engine has therefore six cylinders and the genera arrangement is shown in Fig. 7. The car for five passengers com pletely equipped weighs less than 1800 lb. and has less than 4

moving parts. It has no carburetor or ignition accessories, no clutch, gear shift, flywheel, propeller shaft, universal joints or differential; and uses kerosene as fuel, on which it is claimed to operate very economically.

It is stated that the design was worked out primarily by a Norwegian engineer, but developed to its present state of refinement in America. (*The Accessory and Garage Journal*, vol. 10, no. 11, Mar. 1921, pp. 88–89, 2 figs., *dA*)

MUNITIONS

A New Firearm: The Submachine Gun

Submachine Guns, A. B. Richeson. The submachine gun is a new-comer in the world of firearms. It is really a machine gun reduced to the form and dimensions of a large pistol and is capable of delivering a stream of several hundred shots per minute, firing the 0.45 caliber Army automatic-pistol cartridge.

Three new mechanical principles have been necessary to produce the extreme lightness and simplicity of the new weapon combined with its sturdiness and reliability of functioning. They are the wedge lock, the oiling device, and the new disk magazine feed.

In the breech lock a small wedge weighing a few ounces takes the place of the usual recoil mechanisms. In working with a simple wedge type of breech closure it has been found that the smaller the inclination of the surfaces of the wedge, the smaller the pressure at which adhesion ceases, and, of course, as long as the surfaces adhere they resist any sliding upon each other.

The experiments have further shown that the breech opened when the wedge angle was considerably below the angle of repose, when friction might have been expected to hold the block after the adhesion ceased; and further, with the larger wedge angles considerable pressure in the bore still compressed the wedge between the cartridge case and the wedge housing with considerable force. The explanation of these two phenomena apparently lies in vibrations set up in the mechanism by the rapidly varying bore pressure.

In the rifle mechanism as developed, sufficient pressure remained in the bore when the wedge opened, for the empty cartridge case to be blown to the rear, carrying the bolt (containing the firing pin and firing spring) before it, with sufficient velocity to cock the firing pin when the bolt brought up against the rear buffer, and causing the empty cartridge case to rebound and to be ejected to the front. This movement of the bolt to the rear was against the force of compression of a spring designed to reload the piece.

In investigating the operation of a machine gun viewed essentially as a gas engine, it was found that the friction between the cartridge case and the walls of the firing chamber varied during extraction and at times was excessive due to residual pressure of powder gas within the cartridge case. This variable friction is attributed to different degrees of annealing the cartridge cases during manufacture and to tolerances in diametrical or longitudinal dimensions required in the commercial manufacture of cartridges. The important result, however, is that the ejection of the various empty cases takes place at different pressures and therefore does not occur at regular intervals or with equal ease and rapidity.

To obviate this an oiling device was built in, consisting of felt pads in the breech. Enclosed and protected against dirt, the pads are impregnated with lubricant by an ordinary squirt oil can, and each rearward movement of the bolt lubricates the mechanism afresh. Experiments have shown that it is not necessary to coat a cartridge case with oil to eliminate the friction difficulty in extraction, a very slight smear of lubricant answering the purpose satisfactorily.

The magazine feed is of the disk type, interesting because friction, which has been the great stumbling block in this type of feed, has been largely eliminated by a method of moving cartridges by means of a spiral spring that can be wound with the magazine either loaded or empty. In Fig. 8 the magazine device is, however, not fully illustrated.

The submachine gun is made without shoulder stock or sights, for ordinary rapid fire from the hip, but can be provided with stocks and sights if desired. It fires full-automatically as long as the trigger is held back, but single shots can be fired by quick release of the trigger after each shot. The gun seems to have good ballistic properties. (*Army Ordnance*, vol. 1, no. 3, Nov.-Dec. 1920, pp. 134–136, 2 figs., *dA*)

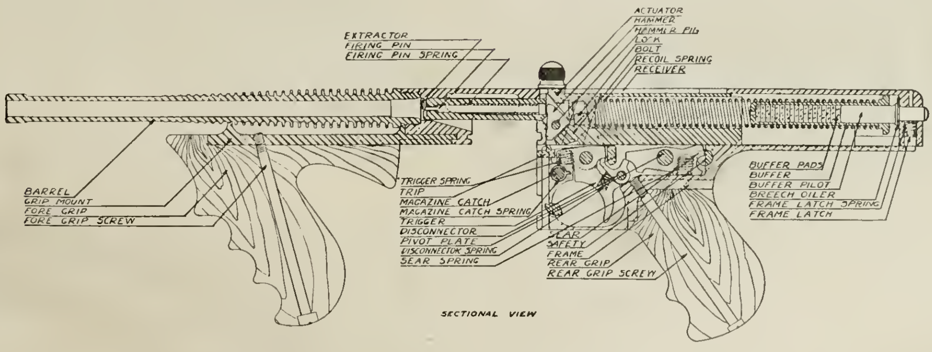

Fig. 8 Sectional View of the Submachine Gun

POWER PLANTS (See also Refrigeration)

Design and Testing of Water-Cooling Towers

Water-Cooling Towers, I. V. Robinson. Description of the types of coolers and methods of testing. The article is the first of two on this subject.

Water-cooling towers are extensively used in Great Britain in connection with the largest central stations where the plant has outgrown the natural supply of circulating water and has to supplement it by artificial means.

Water-cooling apparatus differs considerably in type, but the principle and method of cooling is the same in all types, i.e., bringing into intimate contact with the hot water a large quantity of air at a lower temperature.

The coolers are classified as follows:

1 Chimney type:
  a Natural draft
  b Forced draft
2 Open type
3 Spray type.

In a cooling tower heat is absorbed from the water by the air through two distinct actions: (*a*) Direct heating of the air, and (*b*) evaporation of a portion of the water.

Under the usual working conditions in Great Britain the heat absorbed by evaporation is about 75 per cent of the total heat absorbed, as shown by a brief calculation in the original article.

Natural-draft chimney-type cooling towers are most generally used. The water is admitted at a height varying from 16 ft. to

25 ft. above the sill level and is distributed over the whole area of the tower by main distribution troughs. From these troughs it falls into smaller troughs pitched closer than the larger distribution troughs and is allowed to fall on to the cooling stack by various special methods differing with various makers. Air is admitted usually around the whole perimeter of the tower at the base of the stack, openings about 5 ft. to 6 ft. high being left for this purpose. The various designs differ mainly in the methods used for initially distributing the water over the cooling stack and bringing the water and air into intimate contact.

Some concerns employ cast-iron or porcelain pipes and allow the water to fall into porcelain disks. If the height of fall of the water and the shape of disk are correctly chosen, the water will be broken into a fine spray.

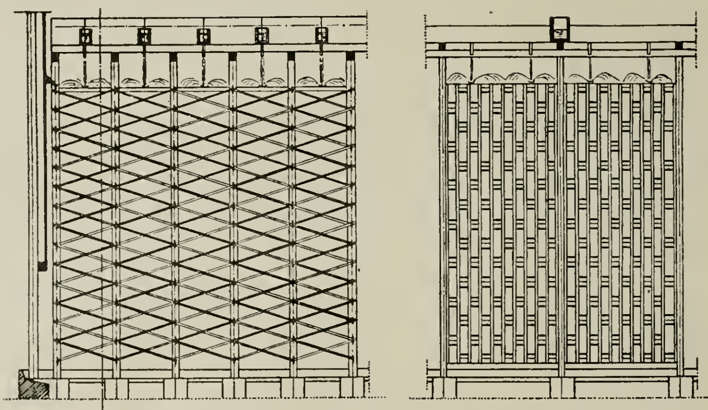
Another method is to use dipper bars let into the side of the main distribution troughs. These bars have concave surface along which the water flows, overflowing then on to the cooling stack. The object in all cases is to divide the water so that it presents a large surface to the air and yet at the same time to allow the air to ascend the tower freely.

It is because of this second condition that the splash system has not found much favor with designers lately.

Fig. 9 shows a section though a cooling stack which depends upon film and not splash. After rebounding from the splasher disks under the small troughs, the water falls on to a number of inclined laths and flows down them. At the lower end of each lath there is a V-notch through which the water passes and then falls on to the upper end of the next inclined lath, and so repeats the process till the bottom is reached. In the stack illustrated the water flows over fourteen inclined laths, seven sloping in one direction and seven in the reverse direction. Each vertical set of laths is comparatively narrow and the sets are so arranged that adjacent laths at any level are inclined in the opposite direction. This alternate arrangement allows a free passage for the air up the stack, the air having to move horizontally only the width of one lath when passing each lath.

Towers are usually built over a tank varying in depth up to 6 ft., and the concrete forming the tank has an important bearing upon the stability of the tower. Many local authorities in England stipulate that a structure such as a natural-draft cooling tower shall be able to withstand a wind pressure of 30 lb. per sq. ft., and do not consider that this condition is met unless the resultant of the horizontal wind pressure and the weight of the tower and the concrete tank to which it is securely attached passes through the middle third of the base. The original article shows how these magnitudes are computed.

The author presents some facts, however, which would indicate that this regulation is excessively stringent, and believes that there would probably be an ample margin of safety if the resultant of the wind pressure and weight of tower and tank passed through the middle half of the base with the tank empty, as the effect of the water which is usually in the tank would be to bring the resultant into the middle third. As regards the testing of cooling towers, it is necessary first to determine clearly the object of the test. Manufacturers usually guarantee that when the tower is dealing with a stated quantity of water per hour at a given temperature, it will reduce the temperature by a definite amount under specified atmospheric conditions; and if the object of the test is merely to ascertain whether or not this guarantee of performance has been maintained, the test is quite simple and very few tests on cooling towers pretend to do more than this. But if it is desired to test the tower completely so as to learn whether any improvement can be made, a much more detailed test becomes necessary, a matter which is briefly discussed in the original article. [*Beama* (A monthly journal devoted to the interests of British electrical and allied engineering), vol. 8, no. 3, Mar. 1921, pp. 227–234, 5 figs., *dp*]



Longitudinal Section. Transverse Section.

Design of Spray Ponds

Spray Ponds, Terrell Croft Engineering Co. Discussion of the design and description of several arrangements of spray ponds and nozzles used for recooling condensing water.

Two types of spray nozzles are shown in Figs. 10 and 11. The purpose of these nozzles is to break up the water into a fine mist, and the nozzles are set either vertically or at an angle—usually 60 deg.—with the horizontal.

It has been demonstrated experimentally (Fig. 12) that, first, recooling is more affected by the air temperature and humidity than by the temperature of the water coming from the condensers; second, that with 80 to 90 per cent relative humidity the water temperature can be lowered to within 12 or 13 deg. fahr. of the dry-bulb air temperature; third, that with 20 to 30 per cent relative humidity the water temperature can be lowered about 8 deg. fahr. below the dry-bulb air temperature; and, fourth, that the loss of water is usually about 6 per cent.

TABLE 2– SPRAY-NOZZLE CAPACITIES, GAL. PER MIN.

Pipe size of nozzle, inches	Pressures on nozzles, lb. per sq. in. 6	6	7	9	10	10
2	54	60	65.5	70.5	75	78
2½	77	85	92	98	103	106
3	115	125	133	140	146	151

To compute the temperature reduction which can be effected by a spray-nozzle installation, the following formula can be used:

$$T_2 = T_1 - \frac{(T_1 + T_x + 920)^4 - 16(T^x + 460)}{16\,(K \times 10^8)}$$

wherein all temperatures are in degrees fahrenheit and T_2 = temperature of cooled water after spraying, T_1 = temperature of water before spraying, $T_x = (4T_w + T_d) \div 5$, T_d = dry bulb-thermometer or air temperature, and Tw = wet-bulb-thermometer temperature. K = a constant = 5.1 for average installations operating at 6½ lb. water pressure, but it may vary from 4.4 to 5.7; it varies with the wind velocity and the pressure with which the water is forced through the spray nozzles.

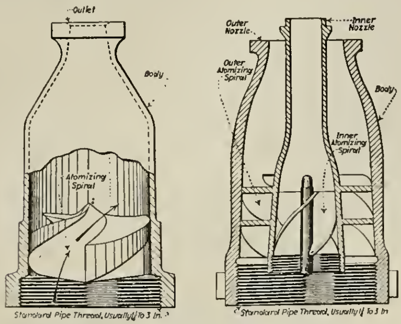
To determine the probable temperature reduction in any locality the average data for this locality have to be consulted. They may be found for a number of places in a table in *Power Plant Engineering*, Apr. 1, 1921, p. 361.

Recooling by spray nozzles may be done in one stage where a cooling of 20 to 30 deg. fahr. is sufficient, or in two stages where a greater range is desired.

The spacing of the nozzles depends mainly upon their design and size. Centrifugal nozzles of 2-in. size are usually spaced about

8 to 10 ft. from center to center, and larger nozzles may be set proportionately further apart.

A typical installation, spraying 4800 gal. per min., consists of nine rows of nozzles with eight nozzles in each row. Thus each nozzle sprays $4800 \div (9 \times 8) = 66^2/_3$ gal. per min. The rows are 20 ft. apart and the nozzles are spread 13 ft. between centers. A 2-in. nozzle (Table 2) at a little over 7 lb. per sq. in. water pressure would meet these requirements.



Figs. 10 and 11 Types of Spray Nozzles

Spray fountains should be surrounded by wind breaks in order to avoid excessive water loss during heavy winds. They may be located on power-house roofs. The power required to operate a spray fountain in connection with the steam-condenser equipment seldom exceeds 1.5 to 2 per cent of the main engine power, and the circulating pump may often be used to deliver the water directly

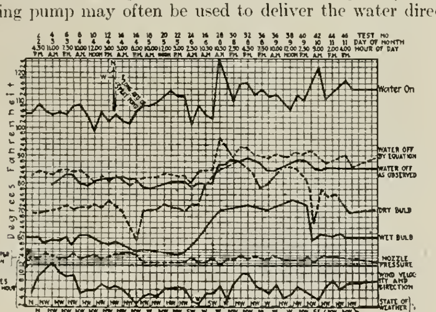


Fig. 12 Data of Spray Nozzle Test (Circulation 5000 Gal. per Min.)

to the nozzles, which cannot, however, be done where barometric condensers are used. (*Power Plant Engineering*, vol. 25, no. 8, Apr. 15, 1921, pp. 408–410, 9 figs., *pd*)

RAILROAD ENGINEERING

Handling 9000 Tons Down a 1.6 Per Cent Grade. Description of methods by which a 70-car train with automatic straight air brakes can be successfully controlled on the Norfolk & Western Railway over comparatively heavy grades.

On the Elkhorn section, one of the worst sections of the Norfolk & Western Railway, as far as grades are concerned, the handling of coal trains has been simplified by electric traction which permits the control of train movements down a 2 per cent grade by regenerative braking. For the rest of the line steam operation still obtains and the problem of train control is an important one, particularly so as the Norfolk & Western uses high-capacity cars, and, in fact, ranks as a pioneer in their introduction. At the present time, for example, the railroad is completing the construction of 500 gondola cars of 100 tons capacity, which is a considerable advance in the development of the high-capacity car. (These cars, are equipped with an entirely new type of six-wheel truck.)

As regards braking, they are equipped with automatic straight air brakes and the test train weighing approximately 9000 tons on a run from Bluefield to Roanoke is described in the present article.

This train was made up to include the Norfolk & Western all-steel dynamometer car equipped to record graphically the brake-cylinder pressure, the train-line pressure and the auxiliary reservoir pressure on the dynamometer car, and also to record the exact amount at which brake-cylinder pressure built up to and dropped below 15 lb. on the first, twenty-seventh, fifty-third and seventieth car back of the dynamometer car.

During the test run the chronograph also recorded various facts such as the drawbar pull of the locomotive, and it may be noted that on the test run the maximum pull of the single Mallet locomotive attached to the head of the train exceeded 120,000 lb. and on several occasions the locomotive developed more than 2500 hp. at speeds between 15 and 20 m.p.h.

The tests are of great interest and cannot be described in detail because of lack of space.

The most interesting of the standing emergency tests was conducted as follows: A 2-lb. reduction was made, then the valve was lapped for 20 sec., after which the brake valve was thrown in emergency position for one minute. In this test the brake cylinder on the first car developed 15 lb. pressure 19.5 sec. after the service application, while the seventieth car developed the same pressure 20.3 sec. later. The maximum brake-cylinder pressure recorded on the dynamometer car with a 20-lb. service reduction was 29.7 lb., whereas with subsequent emergency action a pressure of 56.5 lb. was developed in the brake cylinder. Upon completion of this test the first car released in 9.5 sec. after the brake valve was placed in full release, and the seventieth car released in 122 sec. after the first car released.

The action of the graduated release, which is one of the important characteristics of the operation of the automatic straight air brake, has been carefully tested and successfully demonstrated, and it proved to be possible to handle the train down the steepest grades under perfect control.

On the whole, within eight hours the train effected a gross ton-mileage output somewhat in excess of 900,000 without a hitch, which may be taken as an interesting indication of the state of development of the modern locomotive as well as of the braking equipment. (*Railway Review*, vol. 68, no. 14, Apr. 2, 1921, pp. 515–521, 9 figs., *dcA*)

REFRIGERATION

Columbian Flask Steam Condenser. Description of a condenser said to be extensively used in ice-manufacturing plants. The steam enters at the bottom of the head of the condenser into the first or reboiling compartment formed by baffle plates. It travels then through the entire length of the condenser, ascending into the next compartment, back through the full length of the condenser, again ascending into the next compartment, until it reaches the top compartment at the end of which is provided a small opening for the escape of foul or gassy steam, the two in the center being the main condensing compartments.

The distillate travels back over the baffle plates, descending to the bottom of the condenser in the same manner in which the steam traveled as it ascended over the baffle plates. This distillate reboils on its way back to the bottom of the condenser and is finally carried off through the distilled-water outlet in the bottom of the condenser down into the ice cans below, where it is finally frozen into ice cakes.

The steam entering at the bottom of the condenser is generally from 218 to 220 deg. fahr. with a pressure from 1/2 to 1 lb. The cooling water, which is evenly distributed over the outside of the condenser, is usually from 90 to 100 deg. fahr. The hot steam passing back and forth up through the condenser meets the distilled water and reboils it so thoroughly that by the time the distillate reaches the bottom of the condenser in the reboiling chamber, there is no further need of a separate reboiling, yet the temperature in this lower compartment is at about 212 deg. fahr.

Columbian flask condensers are made mostly by hand. The rivets are finished from the inside in order to leave a smooth surface

on the outside as a protection against the quick collection of alkalis and minerals that are found in the water. They are usually equipped with a 4-in. steam inlet and 2-in. distilled-water outlet, and an additional small outlet in the end of the condenser near the top for the escape of foul steam. (*Refrigeration*, 28, no. 2, Mar. 1921, p. 39, 1 fig., *d*)

SHIPBUILDING

An Entirely Electrically Welded Vessel. Last December at the works of the Electric Welding Company of Gothenburg, Sweden, the first electrically welded ship built in that country (the second on the European continent) was launched. The boat has a flat bottom which extends at both ends right up to the water line. The total length of the vessel is 52 ft. 6 in., breadth 13 ft. $1^1/_2$ in., molded depth 7 ft., and draft 3 ft. 6 in.

The propelling machinery consists of semi-Diesel oil engines intended to drive specially constructed generators for electric welding and air compressors. The boat is to be employed along the seashore for carrying repairs to ships.

Rivets are practically absent and the sides as well as the bottom are smooth and glossy as if cast in one piece. The boat was built under special survey of Lloyd's Register, Bureau Veritas and the Swedish Government Inspection. The engine-room skylight is the only part of the whole ship that is made removable, bolts having been used.

The first entirely welded ship on the Continent was built in 1919 at Caen, France, and is now stationed in the harbor of Le Havre. It was built by a French autogenous welding company and is to be used for the same purposes as the Swedish ship. (*Marine Engineering*, vol. 26, no. 4, Apr. 1921, p. 277, 1 fig., *d*)

SPECIAL PROCESSES (See Engineering Materials)

STEAM ENGINEERING (See also Engineering Materials)

Development of the Stirling Boiler. The original Stirling boiler consisted of a single upper or steam drum and a mud drum, water tubes being expanded into the steam drum and forming drop tubes closed at the lower ends. When the boiler was placed in service, trouble developed through the burning of tubes at the bottom ends.

The first modification was to increase the number of drums by installing two steam drums instead of one. Then a third steam drum and structural-steel supports were added and other improvements made. Some seven or eight years later the water columns were connected to the center drum, in which location a true water level was indicated.

During the last 15 years there have been numerous changes made in the Stirling boiler, either in the effort to meet special and unusual operating conditions, or as a result of improvement in detail of design and construction. The principal improvements in design have been:

1 All steel drums are now placed on the same level, the same being taken from the rear steam drum, this being done largely in an effort to overcome priming troubles arising under certain conditions of feedwater.

2 Protection at the rear steam drum is given by a baffle carried on the front tube of the rear bank which is expanded into the center drum.

3 An arrangement of tubes circumferentially on the mud drum has been provided such as to give a larger superheater chamber, which is important when higher superheats are desirable and which also gives a better access of the superheater headers and handhole caps. The sizes and types ("classes") have also been standardized in a manner to reduce the number manufactured.

A section through one of the new classes is shown in Fig. 13. (*Power*, vol. 53, no. 16, Apr. 19, 1921, pp. 632–634, 7 figs. *dp*)

THERMODYNAMICS

Thermodynamic Cycles of Internal-Combustion Engines

Thermodynamic Cycles in Relation to the Design and Future Development of Internal-Combustion Engines Prof. Wm. J. Walker. A discussion of the various thermodynamic cycles and factors affecting the design of internal-combustion engines. The author claims that the outstanding feature in the thermodynamics of the internal-combustion engine distinguishing it sharply from that associated with steam practice is the necessary inclusion of the variable specific-heat factor in all fundamental, analyses.

He classifies various engine types on the basis of the following three factors:

1 *The method of ignition* employed to initiate combustion. This more or less determines the *combustion efficiency* of the engine.

2 *The method of operation* employed to carry out the thermodynamic cycle of the engine. This more or less determines *the mechanical and volumetric efficiencies* of the engine

3 *The thermodynamic cycle* to which the working fluid is subjected. This more or less determines *the thermal efficiency* of the engine.

Of these three the third is the one discussed in particular detail. Figs. 14 to 16 illustrate the classes into which thermodynamic cycles

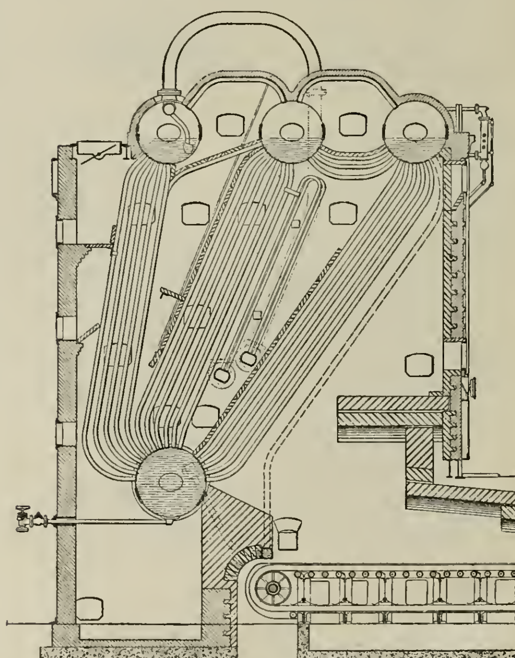

Fig. 13 Section through One of the New Classes of the Stirling Boiler.

may be divided. In Fig. 14 the full-line diagram to the left represents the constant-volume combustion cycle (C.V. Cycle) with compression-volume expansion. This is the standard cycle for most modern engines. With the dotted portion of the diagram included in the full-line left-hand portion, the figure represents the C.V. Cycle with extended expansion. So far as the author is aware, there are no engines in existence operating on this cycle at full load. The entire diagram represents the C.V. Cycle with complete expansion. This is the cycle of the well-known Atkinson engine and also of the Humphrey pump.

Similarly Fig. 15 represents the constant-pressure combustion cycle (C.P. Cycle) with the same three divisions according to expansion. The first division represents the Diesel-engine cycle, the second has no counterpart in past or existing practice, while the third is typified by the Brayton gas-engine cycle.

Fig. 16 represents the class of cycle on which engines, such as the Blackstone oil engine, are operated, and is here called the dual combustion cycle (D.C. Cycle), the heat being imparted some at con-

stant volume and the remainder at constant pressure. This cycle is also divisible as before into three sections according to degree of epansion.

As regards the combustion processes the author defines them in terms of the ratio of the pressure at the end to the pressure at the beginning of constant-volume combustion (α), and the ratio of the volume at the end to the volume at the beginning of constant pressure combustion (ρ). In this connection the author claims that it is incorrect to presume that the efficiency of the constant-pressure

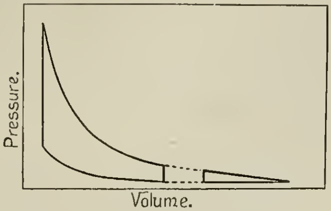

Fig. 14

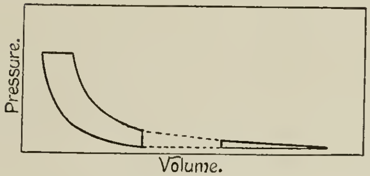

Fig. 15

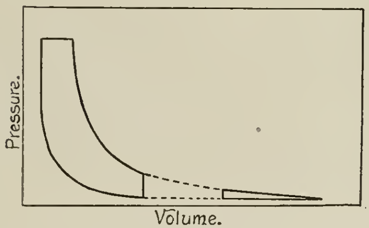

Fig. 16

Fig. 14–16 Diagrams Illustrating Classes into which Thermodynamic Cycles of Internal-Combustion Engines May Be Divided

combustion cycle is theoretically adversely affected by the addition of heat at constant volume, as for instance when a small quantity of oil burned at constant volume is used to facilitate the combustion of heavy tar oils. The discussion of this subject is very interesting, but cannot be abstracted here owing to lack of space.

Referring again to Fig. 16, the author believes such a method of additional fuel injection constitutes really an extension of the fuel combustion cycle and sees in this cycle the possible way of ultimately adopting the Diesel cycle to automobile and aero engines.

As regards the subject of variable specific heat, the author states that the question as to how much of the variability of specific heat is apparent and how much is real does not greatly matter for present purposes, and for all practical purposes it is sufficient to formulate the closely approximate law that the "apparent" specific heat varies directly with temperature. He further comes to the conclusion based on varions recent experiments on air-cooled and water-cooled engines that the brake thermal efficiency actually realized approaches, according to perfection in design, to a theoretical minimum which is identical for all types of engines operating on the same thermodynamic cycle and is independent of engine speed.

The conductivity of the cylinder walls affects brake thermal efficiency, the author admits, but he believes that this diminution in brake thermal efficiency is due wholly to a diminished volumetric efficiency.

The relations between the mean effective pressures, the maximum pressures and the efficiencies of the various cycles are discussed in considerable detail and illustrated by curves. This part is not suitable for abstracting.

As regards the subject of regeneration, a belief is expressed that the raising of steam by means of the waste heat of an engine and utilizing this steam in a high-efficiency steam engine or turbine is the best and most practicable method of increasing overall efficiencies.

Some recent work carried out at the Manchester College of Technology by a research student, R. Koivulehto, in conjunction with the author, on the effect of water injection on the heat distribution in a gas-engine cylinder, has resulted in the determination of actual quantitative values relating to the amount of heat diverted from the jackets to the exhaust per pound of water injected per brake horsepower.

In connection with this, the following regenerative scheme is suggested, experimental figures being adduced in evidence of its value: The proposal is that by running a multi-cylinder engine on a maximum-efficiency dual combustion cycle of compression ratio 8 or 9 : 1, an indicated thermal efficiency of over 40 per cent is possible. By water injection a large proportion of the jacket heat would be diverted to exhaust, resulting, say, in an exhaust discharge of comparatively low temperature and containing 40 per cent of the original heat contained in the fuel. Assuming 20 per cent of this waste heat to be utilized in a high-efficiency turbine of the Rateau type, the total overall efficiency would be raised to the neighborhood of 50 per cent, and this without the introduction of any complicated steam-raising plant. The water injection also would serve to keep down the flame temperatures of the D.C. cycle.

The following figures are typical of the results obtained in the above-mentioned water-injection experiments:

Lb. of water injected per b.hp-hr	0	1.3
Exhaust-gas temperature, deg. fahr.	722	646
Percentage of exhaust heat	27	44
Percentage of jacket heat	34	20
B.hp., per cent	33	30

The paper is followed by a highly interesting discussion which unfortunately cannot be abstracted owing to limited space. (*The Journal of the Institution of Mechanical Engineers*, no. 10, 1920, Feb. 1921, original paper pp. 1235–1258, 12 figs., and discussion pp. 1258–1311, illustrated, *eA*)

VARIA

Adoption of Compulsory Use of the Metric System of Weights and Measures in Japan, Ch.-Ed. Guillaume. A telegram has been received from Shirio Kikkawa, Director of the Bureau of Weights and Measures, in Tokyo, to the effect that the Japanese parliament has passed a law making the use of the metric system of weights and measures compulsory.

In this connection it is recalled that the use of the metric system in Japan has been legal since Jan. 1, 1893, at which time the national Japanese units, shaku and kwan, were respectively fixed as 10/33 of a meter and 15/4 of a kilogram.

In China the use of metric units has been permitted since 1908 and in 1913 a bill was introduced in parliament to make its uses compulsory but has not yet been passed. The same situation exists in Siam. (*Comptes Rendus des Séances de l'Académie des Sciences*, vol. 172, no. 13, Mar. 29, 1921, pp. 795–796, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Research at Michigan

Prof. A. E. White, Director of the Department of Engineering Research at the University of Michigan, has recently presented a paper before the Detroit Section of the S.A.E. on Research—The Bond between the University and Industry. This has been issued as a bulletin by the University.

Professor White explains the plan of work at the University in engineering research. The control of the Department is in the hands of two committees, one known as an Administrative Committee, consisting of the Dean of the Colleges of Engineering and Architecture, the Director of the Department of Engineering Research and the heads of the various departments in Engineering and Architecture; and the second as the Advisory Board and consisting of one hundred men selected from various industrial centers of the state. The Executive Committee of seventeen members of the Advisory Board transacts the largest portion of the work of the Board.

Research Resume of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches which in the opinion of the investigators do not warrant a paper.

Aircraft A1-21. Air Propellers. Prof. W. F. Durand and E. P. Lesley completed in January 1921 an investigation covering the technical characteristics of performance of 12 model propellers in "yaw," that is, with the wind stream oblique to the direction of the shaft and especially when such angles of obliquity are large as in the case of helicopter flight with the propeller serving for both sustentation and traction. Each model was tested at obliquities of 90, 85, 80, 70 and 60 deg. and at wind velocities of 30, 45 and 60 ft. per sec. and for 7 to 10 rotative speeds relative to each wind speed. The data were reduced to coefficients C_1 and C_2 defined by the equations—

$$gT = C_1 \Delta N^2 D^4$$

$$gQ = C_2 \Delta N^2 D^5$$

and these are plotted on an axis of V/ND, where T = thrust, Q = torque, Δ = density of air, N = r. p. s., D = diameter, C_1 = thrust coefficient, and C_2 = torque coefficient.

Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Aircraft A2-21. Air Propellers. Prof. W. F. Durand and E. P. Lesley completed in December 1920 an investigation covering the technical characteristics of ten forms of model propellers at a series of air speeds relative to r.p.m. and included in the determination of the thrust and torque coefficients and efficiency. The thrust coefficient C_1 is defined by the equation $gT = C_1 \Delta V^2 D^2$. The torque coefficient C_2 is defined by the equation $gQ = C_2 \Delta V^2 D^3$, where T = thrust, Q = torque, Δ = density of medium, V = speed, and D = diameter.

Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, California.

Apparatus and Instruments A5-21. Calorimeter. (see *Heat A8-21*)

Automotive Vehicles and Equipment A3-21. Combustion Products. Report No. 2225 of the Bureau of Mines on gasoline losses due to incomplete combustion in motor vehicles, by A. C. Fieldner, A. A. Straub and G. W. Jones, is an abstract of a paper read before the S. A. E. in January 1921. The investigation was made for the purpose of caring for the ventilation of the vehicular tunnel under the Hudson River. The report shows the results of tests extending over ten months and compares the results of these tests with previous tests, giving diagrams and charts. Curves giving various important data are also included. The tests on 101 passenger cars and trucks of various capacities give the following results:

1 Automobile exhaust gas consists of carbon dioxide, carbonm onoxide, hydrogen, hydrocarbons, oxygen, nitrogen and water vapor, the relative proportions of which vary greatly depending on carburetor adjustment, degree of atomization, compression and other elements.

2 The important constituent of exhaust gas regarding tunnel ventilation is carbon monoxide. Physiological tests show that the maximum allowable concentration for an exposure of one hour is four parts in 10,000.

3 The carbon monoxide varied from 0.5 to 14.0 per cent in passenger cars and speed trucks on level grades at from 15 to 20 miles per hour, averaging 7 per cent. With 1½ to 5-ton trucks at 10 miles per hour the average was 7.3 per cent. The average percentage of carbon monoxide corresponds to an air-gasoline ratio of 11.8 This is slightly richer than that required for maximum power. Maximum power mixture is 12.5; maximum-thermal-efficiency mixture, 16.0; complete-combustion mixture, 15.4.

4 The larger percentages of carbon monoxide are produced when the throttle is nearly closed or when the car is standing with the engine idling. The largest quantity of carbon monoxide is produced when the gas consumption is greatest, as when car is accelerated or running up grades.

5 Completeness of combustion varies directly as the percentage of carbon dioxide in the exhaust gas and inversely as the percentage of carbon monoxide. For constant carburetor adjustment combustion is more complete when the motor is operating under full load at normal speed. The primary factor in completeness of combustion appears to be carburetor adjustment. The efficiency of combustion varies from 50 to 95 per cent, the average being 70 per cent.

6 The combustible gas in the average automobile exhaust contains 30 per cent of the total heat of the original gasoline. This means a loss of $400,000,000 per year on the consumption of gas in 1919 with gas at 33 cents per gallon.

7 The majority of motor cars and trucks operate on a rich mixture suitable for maximum power but wasteful for gas economy.

8 The average motor-car carburetor is set for winter operation and not changed in summer. This is shown by the highest percentage of carbon monoxide and richer mixtures found in summer tests.

9 The public should realize the saving resulting from the use of lean mixtures. Taxicab and trucking companies could well afford to employ chemists to make regular control tests.

Address Director, Bureau of Mines, Washington, D. C.

Boilers A1-21. Evaporators. A study of measures to reduce the effects of priming in evaporators was the subject of a thesis completed by D. K. Dungan and H. Stewart. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Cement and Other Building Materials A8-21. Tolerance of Coarse Aggregate Under ¼ In. The Experiment Station of Purdue University has made experiments on the properties of Indiana sands and gravels sieved to different gradings of size. During the last two years the results show that 20 to 30 per cent of the coarse sand which passes over with the pebbles may be allowed to remain in the coarse aggregate without detriment. The report is published by the American Concrete Institute February, 1921. Address Dean A. A. Potter, Engineering Experiment Station, Lafayette, Ind.

Fuels, Gas, Tar and Coke A8-21. Continuous Calorimeter. See *Heat A8-21*.

Fuels, Gas, Tar and Coke A9-21. Third Semi-Annual Motor Gasoline Survey. Report No. 2220 of the Bureau of Mines gives the third semi-annual motor-gasoline survey made in January 1921. One hundred and fifteen samples were collected and analyzed from nine cities. The difference between the averages for the nine cities in this survey and the seven cities included in the 1920 survey is very slight. The analysis of the distillation curves shows that the curve is slightly below the Federal Specifications until the 85 per cent point is reached, when it rises slightly above. The average results from the nine cities are as follows:

Specific gravity	0.744
Baumé degrees	58.3
First drop	113 deg. fahr.
20 per cent	197 deg. fahr.
50 per cent	261 deg. fahr.
90 per cent	377 deg. fahr.
End point	431 deg. fahr.
Average boiling point	264 deg. fahr.
Percentage recovered	95.9

Address Bureau of Mines, Washington, D. C. F. G. Cottrell, Director.

Glass and Ceramics A2-21. Ceramic Industry. Report No. 2212 by D'Orsay A. Lyon to the Bureau of Mines outlines the investigation made by the Ceramic Station of the Bureau at Columbus, Ohio. The work of finding bond clays for graphite crucibles and the investigation of foreign and domestic graphites is almost complete. The Station is working on dolomite refractories for furnace linings. The work of the Station is to produce brick which will not disintegrate in storage or when placed in furnace. It is also working on white pottery clays and Ohio fire clays. Address Director, Bureau of Mines, Washington, D. C.

Glass and Ceramics A3-21. Dissolved Gases in Glass. Dissolved gases in glass is the subject of Bulletin No. 118 of the Engineering Experi-

ment Station of the University of Illinois. The investigation was made by Prof. Edward W. Washburn, Frank F. Footitt, and Elmer N. Bunting. The investigation shows that—

1 All varieties of glass in the finished state contain dissolved gases.

2 The amount of this dissolved gas is sufficient to cause the glass to effervesce violently if the pressure upon it be suddenly reduced while it is in a fluid condition.

3 The amount and composition of the dissolved gas vary greatly with the type of glass and the details of the melting and fining procedures.

4 In the three types of industrial glass examined the volume of the dissolved gases (measured under standard conditions) varied from 0.2 to 2 times the volume of the glass itself.

5 Carbon dioxide, oxygen, and nitrogen were found in varying amounts in the gas.

In addition, as a result of this experimental work a convenient apparatus for measuring and analyzing the dissolved gases was developed, and an improved type of vacuum furnace for the manufacture of gas-free glass was constructed.

The paper gives a number of figures showing the apparatus used and the method of procedure. Price 20 cents. Address Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Heat A8-21. Recording Calorimeter. Technical Paper No. 2 of the Fuel Research Board under the Department of Scientific and Industrial Research of Great Britain has been issued. It is a Report on the Simmance Total-Heat Recording Calorimeter by Thomas Gray and Alfred Blackie. It contains a record of the operation of this instrument on town gas during five months with occasional adjustments. During the second period the instrument was supplied with coal gas and water gas in order to check the accuracy of the gravity governor when subject to rapid and extreme changes of density and calorific values. Tables of results and curves illustrating the experiments are also included. Obtained at 10½d. from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2.

Heat A9-21. Thermometers. The Bureau of Standards requires that partial-immersion thermometers be used for work in which the thermometer is not completely immersed. Few people are willing to make stem corrections for full-immersion thermometers when partially immersed. The advantages of total and partial immersion thermometers are given in the *Journal of Industrial and Engineering Chemistry* for March 1921. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Internal-Combustion Motors A1-21. Combustion Products. See *Automotive Vehicles and Equipment A4-21.*

Machine Design A1-21. Shrink Fits. The Bureau of Standards has investigated the feasibility of making shrink fits on so-called body-bound bolts by contracting the bolts by using liquid air or by expanding the bolt by the use of an explosive within a small hole in the center of the bolt, the bolt having a sliding fit in the hole. The results of the investigation showed that with 1/1000 in. over size for a cylindrical pin contracted by liquid air the withdrawing frictional resistance was equal to 2150 lb. per sq. in., while with an explosive charge the frictional resistance was equal to 2180 lb. per sq. in. Address, S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Machine Design A2-21. Screw Threads. The report of the National Screw Thread Commission has been issued as a Miscellaneous Publication No. 42 of the Bureau of Standards and is obtainable from the Superintendent of Documents at 15 cents per copy. It was abstracted in Mechanical Engineering during June and July 1920.

Petroleum, Asphalt and Wood Products A4-21. Assaying Oil Shales. A convenient and reliable retort for assaying oil shales is the subject of Report No. 2229 of the Bureau of Mines by L. C. Kerrick. Address Director, Bureau of Mines, Washington, D. C.

Properties of Engineering Materials A3-21. Physical Properties. The Bureau of Standards has issued Circular No. 101 which is obtainable from the Superintendent of Documents. It presents in readily accessible form the best available data on the strength and related properties of materials. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Refrigeration A2-21. Properties of Ammonia. The Bureau of Standards has recently completed a set of accurate measurements on the thermal properties of ammonia. The work completed is sufficient for the preparation of a table of properties, and such a table has been issued in mimeographed form. The results do not differ greatly from the tables now in general use. The properties, of superheated ammonia have not been investigated to a sufficient amount for the construction of a table. This will be done. Address S. W. Stratton, Director, Bureau of Standards, Washington, D. C.

Road Materials and Equipment A1-21. Slate Dust in Surface Mixtures. Report No. 2230 by Oliver Bowles describes tests that prove the feasibility of using slate dust as a portion of the mixture used for the surface of asphalt roads. The tests suggest the possibility of this application and indicate that the use of slate flour as a filler would result in improved highways and would utilize the waste from slate quarries. Address Director, Bureau of Mines, Washington, D. C.

Steam Power A1-21. Calorimeter Sampling Tubes. See *Apparatus and Instruments A4-21*, Mechanical Engineering, May, 1921.

Ventilation A2-21. Dust in Air. Report No. 2214 by S. H. Katz to the Bureau of Mines is on the subject of the dust in the air of granite-working plants. To determine the dustiness three methods were used, two of which involved catching the dust particles from a volume of air at high velocity on a sticky-coated glass plate. They were then counted under a microscope. Other samples of dust were obtained by filtering 15 cu. ft. of air through a layer of granulated sugar held in a glass tube. The sugar retains the dust. After this the sugar is dissolved in pure water and a small portion of the water is examined microscopically. The entire sugar solution is then filtered through a pure paper, and after burning off the paper the dust is weighed on a delicate balance. The dustiness of the air is finally expressed in millions of particles per cu. ft. and on a weight basis in milligrams per cu. ft. Address Director, Bureau of Mines, Washington, D. C.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work, and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Air B3-21. Air Flow. The nature of the static pressure changes near the outlet of tubes to check results which show a region of static pressure below the atmosphere, extending back into the tubes and depending on the average velocity of the air; and the static pressure drop along various-shaped tubes, particularly those having an oblong cross-section with circular edges, for various velocities of air, are the subjects of investigation in the Research Department of the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa. Address C. E. Skinner, Manager.

Electricity, General B1-21. Contact Resistance. Contact resistance of various metals under different pressures. Address Prof. Paul Cloke, University of Arizona, Tucson, Ariz.

Fuels, Gas, Tar and Coke B1-21. Automobile Fuels. A study by Prof. C. A. Norman, Engineering Experiment Station, Ohio State University, Columbus, Ohio.

Heat B14-21. Heat Transmission. The effect of air-cell asbestos as a pipe covering for hot-air pipes. Research Department, Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa. Address C. E. Skinner, Manager.

Hydraulics B3-21. Steam Flow in Elbows. A study of the frictional drop due to the flow of steam through elbows. Address A. M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

Metallurgy and Metallography B7-21. Detection of Copper Sulphide Ores by the Use of Audio Frequency Current and Waves. Address Professor Paul Cloke, University of Arizona, Tucson, Ariz.

Steam Power B1-21. Flow of Steam in Elbows. A study of the frictional drop due to the flow of steam through elbows. Address, A. M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

Transmission B1-21. Ropes and Tackle. The Engineering Experiment Station of the State College of Washington is preparing a short bulletin on the Care and Use of Ropes and Tackles. Address Dean H. V. Carpenter, State College of Washington, Pullman, Wash.

Water, Sewage and Sanitation B1-21. Pipe Thawing. A bulletin on electrical pipe-thawing outfits is being prepared by the Engineering Experiment Station of the State College of Washington. Address Dean H. V. Carpenter, Pullman, Wash.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

Chemistry, Inorganic C1-21. Fused Caustic Soda. The action of fused caustic soda on commercial alloys such as cast iron is a problem for which the Mathieson Alkali Works, Inc., at Niagara Falls desires coöperation. Address R. E. Gegenheimer, Chief Chemist.

Metallurgy and Metallography C3-21. Fused Caustic Soda. See *Chemistry, Inorganic, C1-21.*

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

University of Wisconsin D1-21. The Engineering School of the University of Wisconsin has special equipment for testing pipe coverings and complete equipment for air measurement, including a Thomas electric meter with a capacity of from 50 to 200,000 cu. ft. per hour, pitot tubes and thin-plate orifices. The laboratory is equipped for comparative tests of shaft bearings. A 50-hp. Sprague electric dynamometer is arranged for the testing of automobiles. A 15-ton ammonia compressor is available for research work on cold-pipe insulation. The laboratory is equipped with the following apparatus:

A 28-hp. Foos engine for producer gas, city gas, kerosene and gasoline.

A 50-hp. cross-compound poppet-valve, Nordberg engine.

A 25-hp. semi-Diesel oil engine with various small steam engines and internal-combustion engines, including those for automobiles.

Address Prof. A. E. Berggren, Asst. Professor of Steam and Gas Engineering, University of Wisconsin, Madison, Wis.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

American Leather Research Laboratory E1-21. The American Leather Research Laboratory, 180 South St., New York, has been discontinued and the work has been transferred to the College of Engineering and Commerce of the University of Cincinnati. The Tanners' Council of the United States is supporting research work of a fundamental nature and in the environment of a university where men are available who have specialized in colloids and physiological chemistry as well as bacteriology this work can be carried on advantageously. Address Prof. George D. McLaughlin, University of Cincinnati, Cincinnati, Ohio.

Kansas State Agricultural College, E1-21. The Engineering Experiment Station is planning to print three bulletins: namely,

1 Service Tests of Paints and Painting Materials
2 Water Heaters in the Home
3 Work of the Road Materials Laboratory.

The Experiment Station is at work on the following subjects:

1 Heat Transmission of Insulating Materials
2 Endurance Tests of Lubricating Oils
3 Automatic Tests of Ventilators
4 Atmospherical Resistance to Movement of Motor Vehicles
5 Tests of Belt Lacings
6 Temperature Stresses in Rigid Pavement Slabs
7 Wear Tests of Concrete
8 Road-Building Materials of Kansas
9 Concrete in Highway Construction.

In most of these investigations the work is well under way and many data have been obtained.

Address Dean R. A. Seaton, Kansas State Agricultural College, Manhattan, Kan.

North Carolina State College E1-21. The new Laboratory of Mechanical Engineering is about completed and equipment is now being installed. The work is under the supervision of Prof. Wm. J. Dana, West Raleigh, N. C.

Pennsylvania State College E1-21. Engineering Experiment Station. The Experiment Station of Penn. State College has issued thirty bulletins up until May 1920. Of these four deal with cement, concrete and building construction, three with electric substances, five with heating and ventilation, and five with internal-combustion engines and coals. Address Director, Engineering Experiment Station, Penn. State College, Pa.

University of Utah E1-21. Engineering Experiment Station. The Engineering Experiment Station of the University of Utah has published thirteen bulletins up to December 1920 as follows:

1 Test of Utah Brick (out of print)
2 Tests of Macadam Rock
3 The Construction and Maintenance of Earth Roads
4 The Economical Design of Reinforced-Concrete Beams
5 Measurement of Flowing Streams. A Simple, Accurate Method of Using the Weir
6 Leaching a Lime-Zinc Ore with Acids
7 Results of Experiments on Sewer Pipe and Drain Tile
8 Patents Relating to Oil Flotation Processes
9 Report of the Department of Metallurgical Research, State School of Mines, University of Utah, 1914, 1915, 1916
10 Mine Sampling and the Commercial Value of Ores
11 Descriptive Bulletin of the Department of Metallurgical Research, University of Utah
12 The Mineral Industry of Utah
13 Extraction of Potash from Low-Grade Alunite.

Address Director, Engineering Experiment Station, University of Utah, Salt Lake City, Utah.

University of Washington E1-21. Engineering Experiment Station. The Experiment Station at the University of Washington, Pullman, Wash., has issued the following bulletins:

How to Measure Water
Sewage Disposal for the Country Home
Water Supply for the Country Home
Construction and Maintenance of Earth Roads
Fuel Economy in Domestic Heating and Cooking
Cost of Pumping for Irrigation.

Address Dean H. V. Carpenter, Pullman, Wash.

F—Bibliographies

The purpose of this section of Engineering Research is to inform the profession of bibliographies which have been prepared. In general this work is done at the expense of the Society. Extensive bibliographies require the approval of the Research Committee. All bibliographies are loaned for a period of one month only. Additional copies are available, however, for periods of two weeks to members of the A.S.M.E. or to others recommended by members of the A.S.M.E. These bibliographies are on file at the office of the Society.

Steam Power F2-21. Steam Flow. Measurement of Steam Flow in Pipes. A bibliography of 10 pages. Search 3297. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

Petroleum, Asphalt and Wood Products F3-21. Fuels. History and Properties of Petroleum Fuels. A bibliography of 8 pages. Address Arthur M. Greene, Jr., Rensselaer Polytechnic Institute, Troy, N. Y.

CORRESPONDENCE

Contributions to the Correspondence Department of Mechanical Engineering are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

The Engineer Cabinet Member

To the Editor:

It appears that engineering training should be an excellent thing in preparation for public life. An engineer is trained rigorously to avoid error, for a machine that is wrong cannot be made right by bluff, appeals to patriotism, censorship, or propaganda. He usually extends his training to his relations with his fellow-men, and I submit that the average engineer has less trouble with his subordinates than does any other class of men.

But I question Mr. Miller's comment in the April Mechanical Engineering that "Whether or not Mr. Hoover is to be followed by a long line of engineers in high and responsible positions, depends far more upon him and how he shall conduct himself during his term of office than upon anything or anybody else."

The more we examine it the more it appears that Mr. Hoover is an unusual engineer. He is more than a mining engineer or industrial engineer; he is a humanity engineer. He knows not only Americans but Englishmen, Frenchmen, Germans and others. Yet has engineering an old profession, been compelled to wait all these years for Mr. Hoover to blaze the way?

If it is true that we have something that the world needs and has failed to get, the fault is ours. We have not been good salesmen.

Recently an engineer presented an important report to a city council. His report showed careful preparation and he is a man of unquestioned ability. But his attitude was that "Facts, being established, leave no room for opinions, traditions or fallacies." *He* knew they were facts but the council did not. He took little pains to sell the facts to the council.

The human body is a machine, the ultimate achievement of the Great Engineer. It has a pump, with suction and discharge valves, that will run a hundred years without a stop.

The human mind is a wonderful thing, but during the thousands of years of evolution it has been ingrained with mere opinions, fallacies and instincts of various kinds which are harmful today; and due to the facilities afforded by science and particularly by the branch engineering—it does widespread damage when it runs amuck.

All engineers must take hold. No one man can do it all. We must demonstrate that as a group we can be trusted to show a way out of the present state of world affairs.

Joel R. Belknap.

Lansing, Mich.

Concerning Non-Scientific Management

To the Editor:

May I call your attention to the heading of an editorial article in the April number of the Journal? This heading is "A Place for Non-Scientific Management." Personally, it seems to me that the use of such a heading as this in a scientific journal is somewhat bad taste, to say the least. The general impression one would obtain by reading this article is at variance with modern development, and its use in a journal of the standing of Mechanical Engineering does not seem warranted. Doubtless certain of the plant methods suggested are worth while, but if they do fit a particular plant to the best possible advantage, they are scientific and not "non-scientific."

Sanford E. Thompson.

Boston, Mass.

Production Minus Consumption Equals Capital Not Value

To the Editor:

In the Secretary's letter in Section 2 of the March issue of Mechanical Engineering, reference was made to the formula $p - c = v$. I have been accustomed to read and believe that production minus consumption equals capital, not value, and that it is by increment of capital that society is advanced.

The political economy of John Stuart Mill is summed up in the formula: Production minus Consumption gives Capital, and selective limitation of population so that pro rata capital increases is the way of human progress. This seems a prerequisite and a more fundamental law than the "binding time" idea of Mr. Polakov, Mr. Korzybski and Mr. Wolf.

I am anxious to determine whether the practical "conservation of capital" idea as set forth in my paper on Appraisal and Valuation Methods[1] is not the fundamental law we seek to know, and consciously develop and strengthen for social advantage.

"Dogmas," "police forces" and "the man-made law of barristers" are human inventions to hold the gain and to consolidate the advance of the race in conserving capital, and as instrumentalities of progress they should not be disparaged or weakened, unless we wish to risk losing the gain, sliding back and beginning again.

Consider two current topics: (1) A dose of capital in the form of farm tractors, etc., seems to have changed the bandit Villa from something less human into a factor in industrial production; (2) Current reports quote the Bolsheviki leaders as saying that (foreign) capital is the solution of the Russian chaos—they will produce if capitalized.

If Bolsheviki means, as I am informed, those who haven't anything, J. S. Mill's principle of industrial philosophy seems more fundamental than anything enunciated by Mr. Polakov or Mr. Korzybski, for the Bolsheviki are successful at "binding time" but not at conserving capital.

With a full appreciation of the brutalities and hardships of the capitalistic system, I would emphasize "conservation of capital" as the practical instrumentality for industrial and human advancement. Conservation must always take precedence over service in anything that is to continue. This emphasizes, as the essence of the maligned capitalistic system, the idea of abstinence.

Production minus Consumption gives the Abstinence Factor (conservation of service or capital ratio), and where this is high in a nation, society or individual, power increases, and with it, happiness, which is the sensation of increase of power in any form or in any field.

Any "service" or "time binding" which is not geared to conservation of capital does not advance humanity—it may even weaken and destroy it. It is not sound industrial philosophy.

Los Angeles, Cal. David H. Ray.

The Theory of Crowned Pulleys

[A letter received not long ago in the office of Mechanical Engineering raised the question as to the theory on which a crown-faced pulley is used instead of a straight-faced pulley with flanges, and why flanged pulleys are not more generally used. The matter was referred to various members of the Machine Shop Practice Division of the Society and the theory agreed upon by them has been submitted in a letter from F. O. Hoagland, chairman of that Division. A letter was also received from George A. Perry, Springfield, Vt., in which the same explanation was offered. Mr. Hoagland's letter follows.—Editor.]

To the Editor:

The pulley with the crowned face is used because of the well-known tendency of flat belts to climb to the largest diameter of a tapering pulley. The theory for this is illustrated in Fig. 1, in which A is a pulley of exaggerated taper, running in the direction of the arrow. The point at which the belt first comes in contact with the pulley is indicated at D. If the belt is to pass around the pulley without climbing, that is, in the direction of lines G and H, then the side E would have to stretch, as the circumference of the pulley at G is greater than at H.

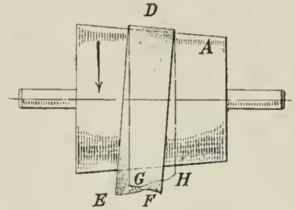

Fig. 1

The stiffness of the belt and its resistance to stretching or bending sideways compel it to follow the direction of lines E and F. If, then, we use a pulley tapering so that the largest diameter is in the center of the path of the belt, it will resist any tendency to deviate in either direction.

As Henry J. Eberhardt expresses it, the highest part of the crown practically acts as a barrier to keep the belt from running off.

It is true, of course, that considerable attention must be given to the amount of crown necessary, according to the various widths of belts and the conditions under which they operate.

Flanged pulleys are frequently used, yet to insure good action on the belt, generous allowances must be made so that the belt will not rub against the flange, and at the same time the flanges should be deep to prevent the belt from riding should it come in contact with the pulley. A low-flanged pulley is absolutely dangerous.

Furthermore, members of the Machine Shop Practice Division all concede that flanged pulleys are much more expensive to manufacture and should be used only where it is impossible to apply crowned pulleys. From experience covering a period of 45 to 50 years, it is recommended that crowned pulleys be used wherever possible.

F. O. Hoagland.

Worcester, Mass.

The Properties of Steam

To the Editor:

The review of Professor Callendar's Properties of Steam abstracted in the April issue of Mechanical Engineering from London *Engineering*, contains two surprising statements, which, if true, place our American steam tables in an unfavorable light. On page 259 occurs the assertion that "the elaborate tables compiled in America on the basis of German experiments and formulas are claimed to fail to satisfy the test which consists in that the work done in a given cycle should be the same whether it be measured on the temperature-entropy chart or on the indicator diagram." Again on page 260, the test—

$$c_p = \frac{dH}{dT}\bigg]_p = \frac{T}{J}\frac{dV}{dT}\bigg]_p \frac{d_p}{d_T}\bigg]\phi$$

is mentioned and the statement is made that all tables based on the German formulas fail to meet this test, the discrepancy being as much as 20 per cent, and that the only tables that do satisfy the test are those based on Callendar's work.

We may assume that the statements in question originated with the author of the review in *Engineering;* for it is inconceivable that Professor Callendar could have shown such ignorance of the recent researches on the properties of steam.

As pointed out in the preface to the Properties of Steam and Ammonia, a steam table should have two qualities, accuracy and thermodynamic consistency. While our older tables may be regarded as fairly accurate, they lack consistency. To such tables the preceding criticisms are quite applicable. If, however, a table is calculated from a thermodynamically consistent formulation, the tests mentioned are automatically satisfied. There are at least two formulations, based on the German experimental data and not all on Callendar's work, that are thoroughly consistent.

It is easily shown that the Goodenough formulation satisfies this test which is asserted to be the exclusive property of Professor Callendar's equations. Using Callendar's notation, the fundamental equation[1] from which the general expression for entropy is derived is—

$$ds = c_p\frac{dT}{T} \quad \frac{1}{J}\left(\frac{dv}{dT}\right)_p dp$$

To obtain the derivative $(dp/dT)\phi$, take ϕ = constant and $d\phi = 0$

Then the equation becomes—

$$c_p\frac{dT}{T} = \frac{1}{J}\left(\frac{dv}{dT}\right)_p dp, \; (\phi = \text{constant})$$

or —

$$c_p = \frac{T}{J}\left(\frac{dv}{dT}\right)_p\left(\frac{dp}{dT}\right)_\phi$$

which is the required expression for c_p in terms of p, v, and T.

The other criticism relates to the quality of areas on the temperature-entropy and pressure-volume planes. The point was forcibly brought out in a criticism of an American steam table in London *Engineering*, June 9, 1916. The heat turned into work in the ideal Rankine cycle is the difference $H_1 - H_2$ between the total heats at the beginning and end of the adiabatic expansion. The work of the cycle is, however, given by the integral $-\int_1^2 vdp$ consequently the first law requires the equality—

$$J\,(H_1 - H_2) = -\int_1^2 vdp$$

If a table is not consistent, the two members of the last equation, as calculated from the tabular values, may show a considerable discrepancy. A table that has this defect may be justly criticized. In the case of any consistent table the two members of the equation are necessarily identical. To show the identity for the Goodenough formulation, take again the adiabatic relation (with $d\phi = 0$)—

$$c_p\frac{dT}{T} = \frac{1}{J}\left(\frac{dv}{dT}\right)_p dp$$

or—

$$c_p dT = \frac{T}{J}\left(\frac{dv}{dT}\right)_p dp$$

The total heat H being a function of T and p, we have—

$$\begin{aligned} dH &= \left(\frac{dH}{dT}\right)_p dT + \left(\frac{dH}{dp}\right)_T dp \\ &= c_p dT + \left(\frac{dH}{dp}\right)_T dp \\ &= \left[\frac{T}{J}\left(\frac{dv}{dT}\right)_p + \left(\frac{dH}{dp}\right)_T\right] dp \end{aligned}$$

The equations[2] for v and H are—

$$v - c = \frac{BT}{p} - (1 + 3ap^{1/2})\frac{m}{T^n}$$

$$H = \alpha + \beta T + \frac{\gamma}{T^2} - \frac{mn\,(n+1)}{JT^n}\,p\,(1 + 2ap^{1/2}) + \frac{cp}{J} + H_0$$

Hence—

$$\left(\frac{dv}{dT}\right)_p = \frac{B}{p} + (1 + 3ap^{1/2}) \quad \frac{mn}{T^{n+1}}$$

$$\frac{T}{J}\left(\frac{dv}{dT}\right)_p = \frac{BT}{Jp} + (1 + 3ap^{1/2})\frac{mn}{JT^n}$$

$$\left(\frac{dH}{dp}\right)_T = -(1 + 3ap^{1/2})\frac{m(n+1)}{JT^n} + \frac{c}{J}$$

$$\frac{T}{J}\left(\frac{dv}{dT}\right)_p + \left(\frac{dH}{dp}\right)_T = \frac{1}{J}\left[\frac{BT}{p} - (1+3ap^{1/2})\frac{m}{T^n} + c\right] = \frac{v}{J}$$

Substituting v/J for the bracket in the preceding equation, the result is—

$$dH = \frac{1}{J}vdp$$

and integrating with J constant,

$$J\,(H^2 - H^1) = -\int_1^2 vdp$$

By a similar procedure it may be shown that Professor Heck's consistent formulation also satisfies these tests.

From the reviewer's statement one naturally receives the impression that the satisfaction of these tests is dependent on the experimental data used. That is, tables based on the German experiments do not meet the requirements, tables based on Callendar's experiments do meet them. Such an inference is entirely erroneous. The satisfaction of these tests is solely a matter of consistency. A table may, however, be consistent and yet grossly inaccurate; such, in fact, was Smith and Warren's table based on Callendar's earlier equations.

In his latest work Professor Callendar has apparently discarded completely the Munich experiments. Whether in so doing he has improved the accuracy of his results is an open question.

G. A. Goodenough.

University of Illinois, Urbana, Ill.

In the method of flying recently proposed by Prof. Raimund Nimfuhr of Vienna, it is intended to imitate the process of flying of an insect, that is, to set up powerful reacting vibrations in the air by a series of very rapid strokes or beats. The underneath section of the wing will take the form of a flexible membrane, which will be set beating or pulsating by the action of pneumatic pumps alternately filling and emptying the air bags in the wing. These pulsations can be made also, according to the theory, to propel a machine forward through the air by the wave-like motion of the atmospheric vibrations they set up. Another essential feature is a flexible extremity at either end of the wing, which, again by pneumatic action, can be made to extend or contract in imitation of the "reefing" of a bird's wing.

Rubber is a peculiar material, contracting when heated and expanding when cooled, and has been largely used for railway buffer and draw springs. An important property that comes into question in some classes of springs is not so much elasticity, as ordinarily understood, but proof resilience, i.e., the energy which a material can store when stretched up to the elastic limit. In that respect rubber far surpasses all other materials, a paper in the February 1921 issue of the *Journal of Industrial and Engineering Chemistry* giving the following values for proof resilience in ft-lb. per cu. in.: Gray cast iron, 0.373; soft steel, 3.07; rail steel, 14.1; tempered spring steel, 95.3; structural nickel steel, 14.7; rolled aluminum, 7.56; phosphor bronze, 4.06; hickory wood, 122.5; vulcanized rubber, 14,600. Thus the spring steel has less than a hundredth of the resilience of rubber.

[2] Properties of Steam and Ammonia, pp. 8 and 10.

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in MECHANICAL ENGINEERING.

Below are given the interpretations of the Committee in Cases Nos. 322 (reopened), 337, and 342 to 346 inclusive, as formulated at the meeting of April 19, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Boiler Code Interpretations

CASE NO. 322 (Reopened)

Inquiry: What material is it necessary to use under the requirements of the Boiler Code for the Y-fitting, also for the safety-valve body, for safety valves to be operated at a pressure of 225 lb.? May cast iron be used for this purpose?

Reply: It is the opinion of the Committee that the Y-fitting referred to may be made of cast iron provided the temperature does not exceed 450 deg. fahr. as stipulated in Par. 12. The safety-valve body need not be of steel unless it is to operate with superheated steam. (See Par. 289)

CASE NO. 337

Inquiry: In applying reinforcing plates within the drums of water-tube boilers to strengthen the shell where the tubes enter, as shown in Fig. 12 (of the Interpretations), what is the requirement of the Boiler Code for the thickness of the plate and the strength of the riveting to compensate for the material removed in forming the tube holes?

Reply: Reinforcing plates shall be riveted to the shell, and the tubes shall be expanded into the inner and outer plates so that the rivets and tubes will hold the plates together in accordance with the rules for stayed surfaces.

The spacing of the rivets with respect to the tubes shall conform to Par. 199 for stayed surfaces using a valve of 135 for *C.* and shall be based on a unit pressure equal to the pressure that can be carried by the inner plate with a factor of safety of 5. (NOTE: Where a reinforcing plate is inside the stem drum it is the inner plate; where it is outside and there is no inner reinforcing plate, the unreinforced shell of the drum is the inner plate.)

The tension in rivets and tubes shall conform to Pars. 220 and 232.

The combined drum shell and reinforcing plate or plates shall have a facter of safety of not less than 5 in ligaments, when calculated in accord with Pars. 192 and 193, also in rivet connections. When reinforcing plates or butt straps are exposed to flame or gas of the equivalent temperature, the joints shall be protected therefrom.

CASE NO. 342

Inquiry: Is it permissible in a heating boiler to be operated at a pressure not to exceed 15 lb. per sq. in., where cross-bracing is required in the side furnace sheet of a locomotive-type boiler between the center line of the cylindrical portion and the crown sheet, to locate a through cross-rod one-half of the staybolt pitch below the center line, as shown in Fig. 15?

Reply: It is the opinion of the Committee that the method of staying described does not conflict with the requirements of the Code when the working pressure does not exceed 15 lb. per sq. in.

CASE NO. 343

Inquiry: What constant will it be necessary to use in the formula in Par. 199 of the Boiler Code, for a surface braced with through stays having inside and outside nuts, but omitting washers?

Reply: It is the opinion of the Committee that where through stays are used with inside and outside nuts, but omitting washers, the constant of 135 should be used in the application of the formula in Par. 199.

CASE NO. 344

Inquiry: In complying with the requirements of Par. 289 for a safety valve used on superheater, is it necessary that the entire casing of the safety valve be made of steel?

Reply: It is the opinion of the Committee that the intent of Par. 289 is that the *body* of a safety valve includes all parts of the body and casing which come in contact with the boiler steam or the steam discharged, and therefore in the construction submitted the casing shall be made of cast steel for use with superheated steam.

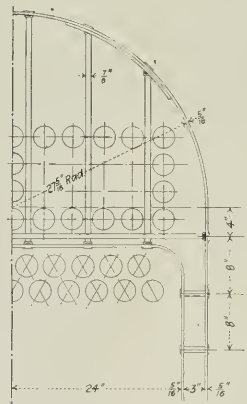

FIG. 15 DETAIL OF SIDE FURNACE SHEET OF LOCOMOTIVE-TYPE BOILER SHOWING STAYING

CASE NO. 345

Inquiry: Is it the intention of Par. 335*b* of the Boiler Code, that hot-water boilers must be built according to the rules for power boilers when either the grate area exceeds 10 sq. ft. or the maximum allowable working pressure exceeds 50 lb. per sq. in., or is it the intention that this requirement applies only when both of the above limits are exceeded?

Reply: It is the opinion of the Committee that the requirement of Par. 335*b* applies only when both of the limits therein specified, are exceeded in the hot-water boiler.

CASE NO. 346

Inquiry: Is it permissible, in the application of the requirements in the A.S.M.E. Boiler Code for safety valves for heating boilers, to take advantage of the proportional difference between bevel-seated and flat-seated valves provided for in the safety-valve rules for power boilers?

Reply: It was the intent of the Committee that Table 9 of the Boiler Code should cover the application of safety valves to all heating boilers, no matter what the character of the seat. Attention however, is called to the fact that where the conditions specified in Table 9 are exceeded, the formula in Paragraph 358 may be used.

MECHANICAL ENGINEERING

A Monthly Journal Containing a Review of Progress and Attainments in Mechanical Engineering and Related Fields, The Engineering Index (of current engineering literature), together with a Summary of the Activities, Papers and Proceedings of

The American Society of Mechanical Engineers

29 West 39th Street, New York

EDWIN S. CARMAN, *President*

WILLIAM H. WILEY, *Treasurer* CALVIN W. RICE, *Secretary*

PUBLICATION COMMITTEE:

GEORGE A. ORROK, *Chairman* ALEX. G. CHRISTIE

RALPH E. FLANDERS JOHN T. WILKIN

PUBLICATION STAFF:

C. E. DAVIES, *Managing Editor*

FREDERICK LASK, *Advertising Manager*

Contributions of interest to the profession are solicited. Communications should be addressed to the Editor.

C 55 The Society as a body is not responsible for the statements of facts or opinions advanced in papers or discussions.

LESTER GRAY FRENCH

LESTER GRAY FRENCH, editor and manager of MECHANICAL ENGINEERING, and for thirteen years editor of the publications of the Society and latterly assistant secretary, died on April 18 at the French Hospital, New York City, from septic poisoning following an operation.

Mr. French was born in Keene, N. H., in April 1869. He received his technical education at the Massachusetts Institute of Technology, from which he was graduated in 1891 with the degree of S.B. He served the year 1891–92 with the Cranston Printing Press Company as draftsman, and then became connected with the International Correspondence Schools, Scranton, Pa., as instructor in mechanical engineering. Leaving this institution in 1895 he went to Providence, R. I., where he entered the employment of the Builders Iron Foundry as assistant to the superintendent. In 1897 he became editor in chief of *Machinery*, continuing in this position until 1906, when he resigned to take up the publication of technical books, among them being one of the earliest American treatises on the steam turbine, of which he was the author. In 1908 he was made editor of the publications of the Society, serving faithfully and ably to the last in that capacity.

Particulars regarding his activities at Scranton and on *Machinery* are given in the tributes printed below from his associates, Professor Goodenough and Messrs. O'Neill, Rogers and Flanders.

Mr. French was elected a junior of the Society in 1899 and became a member in 1912. He was also a member of the Engineers' Club of New York City, and of the University Club of White Plains, N. Y., where he resided.

Resolutions of appreciation of the work of Mr. French were adopted by the Council of the Society and by the Boiler Code Committee at their April meetings, as follows:

Resolved: That the Council of the American Society of Mechanical Engineers hereby expresses its deep regret and sorrow at the loss by death of Mr. Lester Gray French, esteemed Member of the Society since 1899 and for the past fourteen years Editor of its Journal and other publications, acting also as Assistant Secretary.

With rare ability, good judgment and devotion, Mr. French has contributed in an important way to the growth and development of the Society. Not only our own Members, but the Engineering Profession, owe to him a debt of gratitude.

The Boiler Code Committee learns with great regret that Lester G. French, the assistant secretary and editor of the Society's publications, has passed away after protracted illness.

The publications have been brought to a high standard under his direction, enhancing the work and prestige of the Society. Too much credit cannot be given Mr. French for this major activity of the Society, notwithstanding that it is understood that all work of the Society is directed by Committees. Mr. French, by a rare combination of enterprise, vision, tact and devotion has been personally responsible for much of the Society's progress. Mr. French has been a strong supporter of all standardization movements, particularly the Boiler Code movement, and his loyal coöperation in the work of the Committee has been thoroughly appreciated. Be it therefore

Resolved: That the Boiler Code Committee acknowledge and record their appreciation of the life work of Lester G. French, and be it further

Resolved: That a copy of these resolutions be sent to the family and also the Secretary of our Society.

The following letters of appreciation of the professional work of Mr. French and of his sterling personal qualities have been received from members and other friends well fitted by long acquaintance to bring them into review:

LETTERS OF APPRECIATION

When it was perceived by some of us that the Society ought to develop its Journal into something like its present state and the problem of a suitable man to conduct its editorial work arose, I happened to discuss with Mr. French some features of our problem, not thinking he would be available, for I knew that he had plans for the future that I supposed would be more attractive to him. To my surprise, he was interested, and to my gratification he declared that to give up his plans and undertake the work would be very agreeable to him.

Neither of us, as I remember, mentioned the subject of compensation—his interest in the matter was entirely from the standpoint of the service which he saw the prospect of rendering to the profession in helping to develop such a journal of engineering as we had in mind and which he agreed ought to be published and could be best published by a great engineering society.

Though the Society had not at the time achieved greatness, measured by our present standards, he saw that it could achieve it, and his greatest wish and ambition were to help in that work.

Bringing to the service the experience and knowledge based upon successful and high-class technical editorial work, he, with rare ability, tactfulness and complete absorption and devotion, has built for himself a monument that will endure so long as there are engineers having an appreciative understanding of what such work as he did really means.

By nature, retiring and unobtrusive—conservative, yet not afraid of new ideas, nor of departures from the beaten path when they seemed justified, he was peculiarly fitted for the task he undertook to perform; his one failing being that he could not be prevented from driving himself beyond his strength.

He had the faculty of attaching to himself and holding other capable and devoted workers and has left behind him an organization that can continue the work and develop it to the fullest degree; but a very large share of whatever success "The Journal" may hereafter attain will be due to the splendid foundation he did so much to construct.

As his personal friend, acquainted with him since the time when he was a student at "Tech," and as an officer of the Society, in close touch with his work, I find my pen inadequate to fully express my admiration and regard for him, and I feel sure that so long as the Society can attach to itself such men as Mr. French it will continue to grow in power and influence.

FRED J. MILLER.

The life work of Mr. French was such that every one is anxious to give him credit for the wonderful foundation he laid for the publications of the Society, especially MECHANICAL ENGINEERING.

His special qualifications as an editor included the highest ideals, vision and executive ability, and his permanent contribution to the Society was the realization of an ambition for the Society's publications in coöperation with the Publication Committee, and the building of an organization to carry on the work.

Mr. French's inspiration thus lives on to guide the work of the Society, and all will take great satisfaction in trying to make the publications of the Society attain Mr. French's ambition. CALVIN W. RICE.

It has been my pleasure to have known Mr. Lester Gray French for many years. His clear perception of engineering problems, his art as a writer, and his ability as an editor placed him in the front rank of engineering editors. While it was the professional side that brought us together, it is the fine personal qualities that stand out conspicuously now as I think of the many pleasurable occasions when we were brought together, either by painstaking suggestions for a revision of some of my contributions or in the general conferences connected with our society conventions. It was always a genuine pleasure and inspiration to meet him.

JAMES HARTNESS.

French gave what was best in him to our Society, which he served long and well. He was straightforward and upright and always ready to lend a helping hand. He will be remembered by all of his associates as a true and sincere friend. D. S. JACOBUS.

The services rendered by Mr. Lester G. French to The American Society of Mechanical Engineers have been greatly appreciated by those who have been close enough to know of his work. His first thought was always for the good of the Society. He was most diligent, intelligent, and conscientious. The results of his efforts to maintain the publications of the Society in volume and quality will be of lasting benefit. CHARLES T. MAIN.

As an ideal companion, a staunch friend, a true engineer and a remarkable editor, Lester Gray French will remain long in the hearts and memories of his friends and associates in his future-building work for the Society.
George A. Orrok.

In the passing of Lester G. French The American Society of Mechanical Engineers has lost one of the most faithful and efficient servants and many of us have lost a good friend and a pleasant companion. To those who have been in close contact with the work of the Society at its headquarters it is not necessary to dwell upon the importance of the work performed by Mr. French, but to those whose geographical situations make this contact difficult it may not be amiss to remind them of the extent to which a society of this kind is indebted to faithful workers, such as Mr. French, for the growth and prestige of the organization. Presidents, vice-presidents, and managers come and go, they establish policies and change methods of procedure. But no organization of this kind can grow and prosper that cannot command the services of such men as Mr. French, who by faithful and painstaking labor bring the policies of the management into full effectiveness.

It was my great pleasure during the several years I have served upon the Meetings and Program Committee to work very closely with Mr. French and I came to like and admire him greatly. His patience, enthusiasm and good judgment in the difficult task of procuring and selecting good papers for the Society did much to make service upon this Committee a real pleasure, and all who have had the experience of serving in any way in connection with the publications of the Society will join me in recording my profound regret that his usefulness and sunny influence have been brought to an untimely end. It is not too much to say that the present high standards of the publications of the Society and the success that has attended these publications financially are due in no small measure to his energy and good judgment.

The Society has lost a faithful servant, the world has lost a fine high-minded citizen, and many of us mourn the loss of a good friend, whose place will be difficult to fill.
Dexter S. Kimball.

Lester Gray French

During the summer of 1893 Mr. French was one of a group of four young college graduates occupying a room in the Coal Exchange Building, Scranton, Pa. These men were engaged in writing the original instruction papers for the Correspondence School of Mechanics, as it was then termed. Mr. French wrote several of the papers, his special contribution being the Applied Mechanics. Toward the close of the year he was transferred to another office and put in charge of the clerical force that examined student's work.

The papers written by Mr. French were certainly among the best that have been published by the International Correspondence Schools. They showed on the part of the author excellent grasp of the subject-matter, fine judgment in the selection and arrangement of topics, and power of clear exposition. This early experience in a rather unique field of technical writing was undoubtedly a good preparation for Mr. French's subsequent work as an editor.

The high character of Mr. French's work gained him the respect of his associates; his excellent social qualities gained their warm and lasting friendship. In his relations with his associates Mr. French was uniformly courteous and considerate; he was ever ready with suggestions or offers of assistance. Outside of the office he was the ideal companion for an excursion to the hills or a social evening.

The short summer passed too quickly. The group was broken up never to be reunited. But in the minds of each the memory of the association with Mr. French will ever remain.
G. A. Goodenough.

Lester G. French was editor of *Machinery* from 1897 to 1906, a nine-year period during which the machine-tool industry of this country was laying the solid foundations for the rapid development that was to follow. By education, extended study and practical shop experience, Mr. French was well equipped for the editorship of a technical journal in the metal-working field and rendered valuable service in that capacity. He had a natural talent for explaining mechanical principles and describing shop practice, especially for the practical man at work in the industries, who wants his information and data direct and hasn't the time, even if he has the taste, for fine writing. Mr. French knew his subjects and wrote with clearness and accuracy—valuable attributes in a writer whose work is essentially educational. A man of sound character, an associate it was a pleasure to work with.
M. J. O'Neill.

My acquaintance and association with Lester Gray French began in 1899 on joining the editorial staff of *Machinery*. At that time the trade and technical journals presented a variety of industrial and engineering topics before their readers; hardly one specialized as do so many now. We were then passing through an era of change in the industrial world when the importance of the machine shop was just beginning to be recognized and the upbuilding of our present great machine-tool industry was in the early stages. Although personally more interested in power engineering, Mr. French recognized the desirability of specializing on machine-shop practice, machine-tool design and development, and initiated a policy that has been successfully followed by those who came after him in the management of *Machinery*.

Mr. French was a man who endeared himself to his associates. Modest, unassuming and possessed of unusual ability, he rarely asserted his opinions in contradiction of others, but by the force of example and ability won the respect of those with whom he worked. It was with sincere regret that our business association was dissolved when I took on the burden of editorial management of *Machinery* in 1906.

The development of the A.S.M.E. Journal under his expert management was in large measure due to editorial foresight and wisdom. The Journal, in my opinion, stands preeminent among engineering publications. Variety of engineering interests today makes it difficult to edit a publication that will carry universal appeal to engineers of so many affiliations as represented in the A.S.M.E. membership, but Lester Gray French succeeded to a most notable degree. It is with profound sorrow that I write this brief tribute to his personal qualities and editorial ability.
Fred E. Rogers.

Lester French was a friend to me for seventeen years. First as my chief on the editorial staff of *Machinery*, later as a roommate in a house in the west 80's, and finally in the close coöperation of the work of the Society our lines have been in contact throughout that period.

His was a big heart and a high courage in a small body. Untiring energy and absolute honesty of workmanship were his also. He lived and spent himself for the Society. Its position in the professional world today is due in no small measure to his faithful and intelligent administration of the charge laid upon him.

It would be impossible to express in words what was the real beauty of his character; but those who knew him intimately will love best to remember the health and purity of his sentiments. It is not that he was sentimental; but for children, for home, for family, for friends, for country scenes, for all relations and situations that reach to the roots of our common human nature, he kept an open channel to his heart. To have really known him is to have enriched one's life to its end.
Ralph E. Flanders.

Lester French and I were classmates in college, taking the same course and becoming members of the same college fraternity. Later we were near neighbors and for some time lived together. This close personal relationship gave an opportunity for knowing the true man hidden away under his New England reserve and extreme modesty.

Capable and efficient, a quick and a hard worker in spite of ill health for years, he accomplished much in his profession. At the same time he was always interested in those things that make for the general good of the community. A man of high ideals, fond of music, art and literature, gifted with a keen sense of humor, always optimistic, he was the most interesting of companions and the truest and most loyal of friends. A more thoughtful and unselfish man in his home relations could not be found. It was his delight to anticipate every desire of those dear to him and to make the home circle one of constant happiness.

Proud we are of his life and his courageous end; happy, too, in the memory of all the joy he has brought into our lives and of the example he has given us of a life well lived.
Charles W. Aiken.

No activity of The American Society of Mechanical Engineers so directly reaches the great body of its membership as does its publishing business. Few of the Society's membership know to what a large extent the efficient

conduct of its publications has been due to the faithful and efficient service which Mr. French, as the Society's editor, has so long rendered. Under his leadership the Society's monthly journal has been transformed from a barren reprint of papers read at the meetings to a great, influential technical journal.

Mr. French's task has been no easy one. The editor of a publication carried on by a society has to serve many masters, and the masters change year by year. Under these circumstances, to maintain a continuity of policy and of development—and these are necessary to success—calls for rare patience, tact and wisdom.

We all owe a debt to this quiet, modest man whose use of his talents in the service of his profession has been a large factor in its upbuilding; and whose fine personality won for him a wide circle of friends.

Charles Whiting Baker.

I knew Mr. French from the time he first entered the editorial service of *Machinery*. It was my privilege to have been in close contact with him in editorial work upon which I was engaged. The most impressive fact about Mr. French to me was his invariable honesty—honesty to himself, to his ideals, and honesty in his work. This loss is a personal one to me which I feel keenly. The loss to the mechanical engineering profession is greater than anyone knows, even those who were closest to him.

The publication Mechanical Engineering is L. G. French's monument, a living monument and a wonderful one. I regard the success of this publication as being due to him more than to any other individual.

I hope the members of the Society will think of him with pride whenever they see this journal. G. M. Basford.

The life of Lester G. French was a refutation of the theory that an engineer does not concern himself with the human element. Accessible, cordial, never too busy to give his attention to any demand for coöperation or help, his personality was an important factor in the spirit of hospitality of the Engineers' Building. Forgetting himself, he went through the many months of ill health with the spirit of Stevenson. His contributions to engineering through his many years of devotion to the Journal of The American Society of Mechanical Engineers, where the best of engineering theory and practice is recorded, insure a high place for him in the history of engineering achievement, but his warm-hearted interest in humanity and its advancement mean more than this and mark his achievement as a giver of happiness minutes to the world. Frank B. Gilbreth.

My own experience with Mr. French leaves a very happy impression in my mind. He always seemed to have the interest of the Society at heart and to be high-minded about it. I went into his office many times and always came away with a feeling of having been helped. It will be very difficult to replace him. Ira N. Hollis.

The Society has lost a splendid servant, the engineering profession one of its outstanding spokesmen and all of us a loyal friend. We have experienced a very real loss. Morris L. Cooke.

The Society has lost a very useful and efficient member who had its interests a theart at all times and with whom it was a great pleasure for his associates to work. Frederick A. Scheffler.

All this he was—and more—to those whose privilege it was to be in daily association with him in his work, and who, having shared in his clean enthusiasms and experienced the unfailing kindliness and consideration it was ever his nature to bestow, will hold him in affectionate and enduring memory.

Memorial to Frederick Winslow Taylor

The Taylor Society, formerly the Society to Promote the Science of Management, has recently issued a volume as a memorial to Frederick Winslow Taylor. This volume contains addresses delivered at the funeral of Mr. Taylor on March 24, 1915; at a memorial meeting held under the auspices of the society at the University of Pennsylvania, October 22, 1915; and at Mr. Taylor's home, Philadelphia, October 23, 1915.

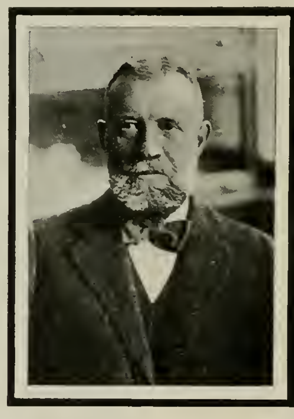
The speakers at the funeral of Mr. Taylor were James M. Dodge and Morris L. Cooke. Those who spoke at the memorial meeting on October 22 were Harlow S. Person, president of the society, Rudolph Blankenburg, mayor of Philadelphia, Carl G. Barth, Henry L. Gantt, Sanford E. Thompson, Louis D. Brandeis, and James M. Dodge. Papers by Charles de Freminville, Paris, Prof. A. Wallichs, of the Royal Polytechnic School of Aix-la-Chapelle, Germany, Henri Le Chatelier, Institute of France, and J. J. Sederholm, University of Helsingfors, Finland, abstracts of which were read at the memorial meeting, are printed in full in this volume.

Copies of the volume have been deposited in the principal public libraries and libraries of engineering societies of the United States and of foreign countries, where they may serve as an inspiration to the thousands who have accepted and are putting into practice his teachings.

GEORGE J. FORAN

George Jesse Foran, manager of the condenser department of the Worthington Pump and Machinery Corporation and the associated companies of the International Steam Pump Company, died Thursday afternoon, May 12, at his home in New York City, after an illness of some weeks.

Mr. Foran was born in Bosten, Mass., Jan. 22, 1862. He was graduated from the Massachusetts Institute of Technology in 1883 and in the fall of that year entered the works of The Deane Steam Pump Company, with which firm he remained until 1886. He then became associated with the George F. Blake Manufacturing Company, where he served as salesman in the engineering field for several years, later acting also as consulting engineer, with special reference to engineering design and construction of water works, condensing and air-compressor installations, and tests and investigations in New England. Upon the completion of the new Blake Works in East Cambridge he became office manager and head of the estimating and cost department, originating the cost



George J. Foran

system then installed. Later he returned to the engineering sales department.

In 1901, after the International Steam Pump Company was formed, Mr. Foran went to New York to accept the position which he filled up to the time of his death. During the war he served upon the committees on condensing apparatus of the U. S. Shipping Board and War Industries Board and as chairman of the American Engineering Service of the Engineering Council, which handled all questions of personnel between the various departments of the U. S. Government and the four national engineering societies.

Mr. Foran was a leader in the development of high-vacuum apparatus from the very beginning, and was responsible for the design of a large number of important installations of this type in the United States. He also accomplished a large amount of original investigation work in the several fields of mechanical engineering.

Mr. Foran was not only a collector of works of art and a connoisseur of considerable attainment, but was also especially well posted on tennis and a valued contributor to various publications, all of which is illustrative of the versatility of the man.

Mr. Foran became a member of The American Society of Mechanical Engineers in 1887 and was active in its committee work, especially as chairman of the Condenser and Heater Sections of the Power Test Code Committee and as a member of the Publication Committee. By virtue of his special knowledge of numismatics he was appointed on the new committee of the Council on Design for the A.S.M.E. Medal. He was also a member of the Verein Deutscher Ingenieure, the American Association for the Advancement of Science, the Engineers' Clubs of New York and Boston, and the Mohawk Golf Club, Schenectady; and an associate member of the American Society of Naval Engineers.

Mr. Foran's wise counsel will be missed at the Society's head-

quarters, where he was a frequent visitor. His interest in the work of the Society was uniformly great, and he was always ready and willing to render assistance to the Secretary's office upon any matter of inquiry. He was particularly close to the committee activities and to the work of the New York Section, and these especially will feel the loss of his friendly interest.

Faithfulness of Committees

The Society has been very proud of the devotion of ist Boiler Code and other Committees, who over a long period of years have turned out such valuable work at much personal sacrifice, but we doubt if there is any record of attendance on a protracted conference quite equal to the following:

The Joint Committee of the American Society of Civil Engineers, the American Society for Testing Materials, the American Railway Engineering Association, the American Concrete Institute and the Portland Cement Association, on Standard Specifications for Concrete and Reinforced Concrete, recently met in the rooms of the Society on a Wednesday at nine o'clock, and continued almost uninterruptedly until midnight. On Thursday they met again at nine o'clock, and with similar persistency remained in session until half-past three on the morning of Friday. They again assembled at nine-thirty on Friday, and continued until ten o'clock Friday night, convening for the fourth day on Saturday morning.

It is not to much to say that such sacrifice for the benefit of the industries and the engineering profession cannot fail to advance not only the progress of the arts and industries, specifically, but the general prosperity of our whole nation.

Calvin W. Rice.

Governor James Hartness Awarded John Scott Medal

In recognition of his development of the flat turret lathe, used in making artillery, James Hartness, governor of Vermont, was awarded the John Scott Medal at a meeting of the American Philosophical Society held on April 23 at Philadelphia.

In 1888 Mr. Hartness became associated with the Jones and Lamson Machine Company of Springfield, Vt., which specialized on turret lathes and was then manufacturing a practically standard lathe in the form of a high turret machine with various features of power feed, lever-operated back gears, etc. Mr. Hartness immediately began the development of the flat turret lathe, embodying the principles now universally used in all turret lathes for doing bar work. The principle feature of the improvements was the provision of adjustable blades and back rests in the same holder, to which the severe strains of cutting were thus confined without permitting deflection and lack of truth, even in turning the most slender variety of work.

The John Scott medal is provided for by the income of a fund bequeathed in 1816 to the City of Philadelphia by John Scott, a chemist of Edinburgh, Scotland. Up to the present year a sum of $20 has been presented with the medal, but the fund has accumulated to so large an amount that by a decree of Court the Board of Directors of City Trusts was authorized to increase the premiums to an amount not exceeding $800. The award to Governor Hartness is one of the first to be made according to the revised provisions.

THE HYDRAUCONE REGAINER, ITS DEVELOPMENT AND APPLICATIONS IN HYDROELECTRIC PLANTS

(Continued from page 380)

seen that the use of the hydraucone regainer on low-head plants is almost a necessity if reasonably good efficiencies are to be obtained. These comparative efficiencies are based on the wheels operating at their best speed and best efficiency, that is, when the discharge from the runner is nearly axial. At any other speed or gate opening the discharge of the water wheel is accompanied by more or less whirling, that is, the absolute velocity of the water leaving the runner is much greater at full load than given in Table 1. Furthermore the whirling action of the water in the discharge is much more effectively used in the hydraucone regainer than it is in the curved draft tube, because of the radially extending passages within which this whirling action produces outward pressure by centrifugal force.

The field of application of the hydraucone regainer will be greater on low-head plants, although it is now being installed in connection with two 40,000-hp. units which are to operate under a head of 421 ft. Hydraucone regainers are in operation or in course of construction in twenty-five hydroelectric power plants, being used with horizontal-shaft as well as vertical-shaft wheels. These hydraucone regainers are to operate under heads varying from 8 ft. to 421 ft. and with water wheels developing from 150 to 40,000 hp.

The most notable installation of the hydraucone is that in Station No. 3 Extension of the Niagara Falls Power Company at Niagara Falls, New York. Unit No. 16 is equipped with a hydraucone regainer of the flat-plate type, as shown in Fig. 17. At the time of the purchase of the water wheel for this unit it was still argued by some that curved draft tubes of proper design would

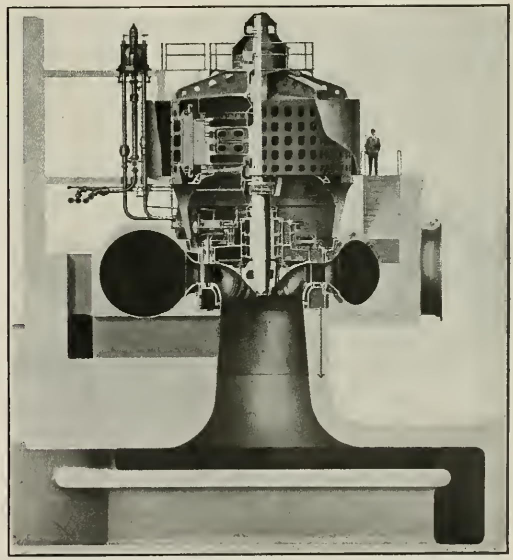


Fig. 17 Hydraucone Regainer of Flat-Plate Type Installed in Station No. 3 Extension of the Niagara Falls Power Company

give as high an efficiency as that claimed for the hydraucone regainer. The engineers of the Power Company accordingly conducted a long series of experiments with various devices, which finally resulted in the development of a conoidal chamber with a cone center similar to that shown in Fig. 1 for units Nos. 16 and 17. The best model with cone center had the proper-shaped conoidal chamber for regain, and when the cone center was removed from the model, it was found that the efficiency was no lower than with the cone in place. The use of the new substitutes for curved draft tubes at this plant resulted in a water-wheel efficiency of 93 per cent being obtained, which is corroborative evidence of the value of the hydraucone principle for the regaining of pressure from velocity

Every one familiar with hydroelectric power-house operation where curved draft tubes are employed has frequently noticed the boiling and disturbance of the water at the outlet from the curved tubes. This disturbance is clearly an evidence of inefficiency and loss of energy which should be more effectively utilized. The hydraucone regainer provides a means for efficiently regaining the energy discharged from the runner for useful effect upon the water wheel within the limited space available in the power-house foundations.

The Essentials of an Engineering Education

Joint Meeting of New York Section of A.I.E.E. and Metropolitan Section of A.S.M.E. Discusses Training of Practical and Theoretical Engineers

THE problem of engineering education has received much attention during these years of reconstruction following the war. That phase of the problem dealing in particular with the theoretical engineer was considered at the evening session devoted to the subject of engineering education by the New York Section of the American Institute of Electrical Engineers and the Metropolitan Section of The American Society of Mechanical Engineers on April 22, 1921.

Dr. Comfort A. Adams acted as chairman and in opening the meeting emphasized the fact that there are two ways of carrying on an engineering educational institution. One is to offer courses which will supply the students with the superficial knowledge of the practical side of the subject, and the other is to provide the scientific foundation upon which engineering is built; to teach him to scrutinize the data upon which he bases the analysis for the solution of any problem, and then to build on that foundation a structure of his own. Unless engineering education is scientific, in its foundation and in its method, it is not education at all.

Walter Rautenstrauch, professor of mechanical engineering at Columbia University, was introduced as the first speaker. He stated the topic of the evening as The Theoretical Engineer—What Is He? Is There a Place for Him? And How Shall He Be Trained? In his treatment of the subject he divided engineering into two general classes, theoretical and practical. The practical engineer he defined as one able to follow a precedent; of the operating type, able to construct something new but within rather limited range. To illustrate what he meant by the theoretical engineer, Professor Rautenstrauch outlined some developments in mechanical engineering and showed how men of genius well grounded in the science of mathematics and physics, such as Unwin, Fairbairn and Rankine, studied the failures in machine parts and developed therefrom the science of the strength of materials and machine design. He also used the work of Rankine, Clausius and Hirn in thermodynamics, and Reuleaux, Unwin, Robinson and MacCord in kinematics as examples of the scientifically trained theoretical engineer. He further explained the capacity of the theoretical engineer as one who not only is informed on scientific facts and laws but also is able to recognize their embodiment or absence in any engineering project. In the ability to do this Professor Rautenstrauch drew a fine distinction between the purely scientific or academic type of mind and the engineering type of mind. The academic type is illustrated by the student who is able to solve a complete mathematical problem when all the facts are clearly set before him. It requires an entirely different type of mind, however, to take a particular problem, to determine the scientific principles applying, to set forth the facts clearly and to arrive at a conclusion through the capacity to recognize just what the problem is. This type of mind is the engineering type of mind.

Professor Rautenstrauch was positive that there is a place for the theoretical engineer, especially as we are now entering upon an era of refinement when the rough constructive work formerly performed is no longer found satisfactory. The speaker felt that the young engineer should be encouraged to enter industries which have not been touched at all by the scientific engineer, such as cotton and rubber mills, where the engineer is generally the master mechanic. In the training of the theoretical engineer he emphasized the importance of teaching the complete theory, not a partial theory, and of imparting the theory of engineering which bases engineering not only on the sciences of mathematics, physics and chemistry, but also upon economics.

Unless a machine can be built cheaply enough to meet the demands, it should never be built; and there is absolutely no use in designing a machine if its cost of production or operation exceeds what can properly be paid.

The effect of a proper amalgamation of the purely scientific and technological aspects of engineering with the economic and commercial principles upon which successful practice is founded, is to create in the student that sense of proportion and judgment which tends to economize his efforts in contributing to scientific progress and invention.

Professor Rautenstrauch also stated that there is no question in the minds of thoughtful men that the most important thing in an engineering education, or in a college education in general, is the inspirational value of the instructor. Unless the student is guided to a desire for service; unless he is inspired with his work so that he loves it and wishes to use his talents for the service of his fellowman, that student fails to be educated.

F. L. Bishop, dean of the school of engineering at the University of Pittsburgh, in his opening remarks endorsed Professor Rautenstrauch's words urging the young engineer to enter new industries. He divided engineers into two classes, the general engineer and the theoretical engineer. The general engineer is the man who has a broad general knowledge of engineering subjects, and can apply that knowledge in an effective way to present engineering problems. The theoretical engineer is a man highly trained in the fundamentals of science and mathematics who can apply research results to engineering. Dean Bishop likened the theoretical engineer to the pioneers who link up the discoveries of the explorer with the known world. He takes the new discoveries of pure science, examines them, determines their application to a given industry, and indicates the manner in which they may be effectively applied. The general engineer then carries on the manufacturing of this material according to the laws laid down.

In the training of the theoretical engineer Dean Bishop said that the theoretical engineer should have a knowledge of the industries and how scientific discoveries as such are applied which can be obtained only by actual experience in industry, and which should be obtained at as early an age as possible. A portion of this knowledge of industry can best be obtained in some form of the so-called coöperative system of engineering education, the object of which is to give the student a background upon which he can base his theoretical courses and to provide him with a very necessary inspiration. It makes the college courses real; he appreciates their value.

Criticism that the engineering schools have weakened their theoretical and laboratory courses in order to introduce more practical work is appearing with greater frequency. The faculties of engineering schools receive many recommendations from practicing engineers who believe that the curriculum should be made stronger in their particular fields.

However, teaching is in itself possibly the greatest of all professions, and the members of a faculty understand quite clearly just what the boy from high school can absorb. The practicing engineer seldom has any conception of these limitations.

Dean Bishop then proceeded to discuss the report of the Joint Committee on Engineering Education presented by Dr. Mann and the study by Professor Walters on scholarship and eminence in engineering, reaching the conclusion that taken together the two furnish an instance of positive correlation between intellect and character. In other words, those men who rank high in the knowledge of fundamentals also rank high in character, judgment and efficiency. Thus the scholastic standing of the engineering graduate is a measure of his character, his judgment, and his efficiency.

In closing, Dean Bishop stated that there is such a person as a theoretical engineer, and that his place is between the pure scientist and the general engineer. He can be trained, but there will not be any large number of men so trained because the pay of such men at present is entirely inadequate and the engineering schools of the country are not sufficiently well manned or equipped. There is, Dean Bishop affirmed, no first-class engineering school to be found in America.

In support of the last and rather startling statement made by Dean Bishop the chairman said that he would guarantee to take the graduates in electrical engineering from any institution in this

country and prove in a five-minute oral examination of each one, in 98 or 99 per cent of the cases, that the men do not understand in any thorough fashion the fundamentals of the subject; that in most cases they do not even know the meaning of the words they use; that they are carried through analyses of comparatively complicated problems, but in a machine-like superficial way, neglecting most of the variables, so that they get into the habit of a kind of loose thinking which so affects all their work that they cannot be counted on for any sound results.

C. R. Dooley, of the personnel and training department of the Standard Oil Company of New Jersey, told of the need in that company of the intensely trained research man and his importance to engineering development. In the training of engineers he stressed one point as most important, and that is that the process of education should be one that would help the man along the line in which his tendencies lie.

In the discussion following the presentations of the evening, H. B. Shaw, of the Henry L. Doherty Company, spoke about the work that his company does in the selection of technical graduates. Mr. Shaw quoted some of that company's specifications for technical graduates: "The graduates should be men who have been trained to think for themselves, have conservative judgment but are not bound by precedent; who can be trusted to try out new and untried methods; men who think straight and think through to conclusions; men who having will for action, act promptly, effectively and justly; men who quickly familiarize themselve swith a situation, all its vital factors, and then form sound judgments which they have the ability to express so as to convince and stimulate others." In closing he stated as his belief that engineers should be trained thoroughly in fundamentals, and should gain an understanding of the larger problems of life, even if they later specialize theoretically.

Capt. O. S. Beyer, consulting engineer, New York City, emphasized the need of the engineers' having a more complete understanding of the economic principles governing their work.

Dr. Harlow S. Person, managing director of the Taylor Society, made three points: First, engineering means something bigger than it meant when the term was first used. It embraces the discovery of new principles and laws, the application of these practically, development work, management work and large administration work. Engineering education is responsible for training men for these functions.

Second, engineering curricula do not contain enough subjects in management, administration and business in general.

Third, training must be fundamental, making the student familiar with fundamental principles common to the various fields of engineering, including management engineering and human engineering.

Mr. Farley Osgood, chairman of the New York Section of the A.I.E.E., emphasized the need of training the student to think for himself. The problem of an engineering education, he stated, resolves itself into straight thinking.

Prof. W. I. Slichter bespoke a broad training for the engineer in the cultural subjects, such as history, economics, etc. He desired to see engineers taking a larger part in the entire activities of the human race.

News of the Federated American Engineering Societies

Participation in Government Reorganization

THE American Engineering Council has recently made several important decisions in regard to its relation to the reorganization of Government departments. Acting upon the recommendation of its Committee on Public Affairs, it will not concern itself with the general reorganization activities of the Government but will confine itself to promoting a nation-wide movement for the establishment of a National Department of Public Works. It is felt that the membership of the Federation can be of greatest service to the nation by confining their efforts to public matters closely related to the engineering profession.

The organization and equipment of the National Public Works Department Association has been taken over by the American Engineering Council and state organizations will assist in the program. At a meeting of the Council to be held in St. Louis on June 3 a detailed plan for renewing the public works campaign in every state will be considered.

Many leading industries, universities and technical organizations are represented in the national organization. Among the educators are Dean George B. Pegram of Columbia; Professors George F. Swain of Harvard, W. B. Gregory of Tulane, T. U. Taylor, University of Texas, J. W. Votey, University of Vermont, W. H. Kenerson of Brown, and C. E. Condra, University of Nebraska, and Dean John H. Dorroh, University of Mississippi.

At a hearing before the Senate Committee on Education and Labor early in May, Mr. Wallace, speaking in behalf of the F.A.E. S. and of the National Public Works Department Association, proposed joint consideration with the public works plan and suggested that modifications be made in the bill for the establishment of a Department of Public Welfare.

Mr. Wallace stated that the Federation does not take a definite stand either for or against the establishment of a Department of Public Welfare, but does urge the vital necessity of a proper distribution of bureaus if Government reorganization is to be effected. The Federation advocates that all the major engineering, construction and research work of the Federal Government be centered in a Department of Public Works, to supersede the Department of the Interior. Other bureaus now in the Department of the Interior must therefore be placed in other departments. Inasmuch as the provisions of the bill for the Department of Public Welfare which is under consideration by the Senate Committee provides for a number of such bureaus and activities, the Federation believes that the bill should be so modified as properly to assign those bureaus that would not be included in the proposed Department of Public Welfare.

Among the bureaus which the McCormick bill, which provides a Department of Public Welfare and a Department of Public Works, would place under the jurisdiction of the latter department, are the General Land Office, the Geological Survey, the Bureau of Mines, the Reclamation Service, the National Park Service, the Division of Capitol Buildings and Grounds, and the Alaskan Engineering Commission.

Licensing of Engineers Exciting Widespread Interest

Interest in the subject of licensing or registering of architects, engineers and land surveyors has become widespread and persistent. Eleven states have passed laws, some providing for licensing of all three professions, some for only one or two of them. These are Colorado, Florida, Idaho, Illinois, Iowa, Louisiana, Michigan, New York, Oregon, Virginia and Wyoming.

In New York the law passed May 14, 1920, has been amended by recent legislation to make it more workable. When these amendments were being considered at a hearing before the State Board for Licensing Professional Engineers, the Department of Education and the Senate Judiciary Committee in February, it was proposed by a group of engineers to further amend the law by eliminating the clause exempting corporations and partnerships from the necessity of being licensed. It was argued that lawyers and doctors cannot incorporate to practice their professions and that engineers ought to be on the same basis. The elimination of the clause was strongly opposed by a second group of engineers and the bill as finally signed by the Governor on May 6 retains it.

The clause in the New York State law is in effect Section 14 of the Recommended Uniform Law for Registration of Architects, Engineers and Land Surveyors, drawn up in 1919 by a committee of Engineering Council. This clause states that "a corporation or partnership may engage in the practice of architecture, engineering, or land surveying provided the person or persons connected with such corporation or partnership in responsible charge of such practice is or are registered as herein required of architects, engineers and land surveyors, or is or are otherwise authorized to practice."

The New York State Engineers' License Bill (now Chapter 581, laws of 1921) took effect upon the date the Governor affixed his signature. All engineers practicing in the State must be registered before May 1922, no matter what branch of engineering they are following.

A printers' strike in Albany has held up the distribution of copies of the bill and of application blanks. Persons who desire blanks should, however, write immediately to the Bureau of Education, Albany, N. Y., and request that their names be placed on file. They will then receive applications blanks as soon as they are available.

At a meeting of the Executive Board of the American Engineering Council on April 16 a representative of those who object to exempting corporations from the necessity of being licensed asked to have this "Model Bill" of Engineering Council referred to a special committee for revision with respect to reconsideration of the rights of engineers to practice their profession through partnerships and corporations. The Executive Board decided to do this, but considered the Licensing Committee which drew up the "Model Bill" a more appropriate body than a new special committee to take under consideration both sides of this important question.

Formation of the Personnel Research Federation

The formation of the Personnel Research Federation under the auspices of the National Research Council and Engineering Foundation links together 250 scientific, engineering, labor, management and educational bodies for the purpose of bringing about interchange of research information about men and women in industry and commerce, encouraging research through individuals and organizations, and coördinating research activities on a nation-wide scale. It aims to increase the efficiency of all the personnel elements of industry—employer, manager, worker—and to improve safety, health, comfort and relationships. Its immediate purposes will be to learn what organizations are studying one or more problems relating to personnel and the scope of their endeavors, and to determine whether these endeavors can be harmonized, duplication minimized, neglected phases of the problems considered, and advanced work undertaken.

Robert M. Yerkes, representing the National Research Council, has been elected chairman of the Federation, and Samuel Gompers, representing the American Federation of Labor, vice-chairman. Robert W. Bruere, who represents the Bureau of Industrial Research, was chosen treasurer, and Alfred D. Flinn, representing Engineering Foundation, secretary. Beardsley Ruml, assistant to the president of the Carnegie Corporation of New York, was selected as acting director.

Dr. James R. Angell, president of Yale University and past-chairman of the National Research Council, in an address delivered before the preliminary conference at Washington in November 1920, summarized in the following words the kinds of problems which should receive attention from the organization then proposed:

> Certain of the hygienic problems of modern industry exemplify cases in which a thoroughly scientific study of causes and effects is possible with convincing conclusions regarding practice which will safeguard the health and vigor of all concerned. Not a few highly important results have already been attained in this field. The effects upon industrial productivity on the one hand, and physical vitality on the other, of good and bad ventilation, of good and bad light, of high temperatures, of irritant fumes, of dust and other similar features are, theoretically, at least, within the field of scientific analysis and the ascertainment of demonstrable fact. Similarly, and in a different zone of inquiry, it should be possible to secure thoroughly reliable data regarding the dominant causes of unrest in our industries, of excessive turnover and the like. Many other instances of the same kind will suggest themselves to all who have experience in the industrial field.

U. S. Patent Office Relief Imperative

In an address before the Washington Section of the A.S.M.E. on April 28, Hon. Thomas E. Robertson, U. S. Commissioner of Patents, gave statistics showing the serious situation existing in the Patent Office because of the low salary scale which is causing an exodus of both patent examiners and clerical force to private employment. In a little over a year, it was stated, 110 of the force of examiners numbering 437 have resigned. During the first three weeks of March six highly trained experts resigned to accept outside positions offering salaries two or three times as great as those they were receiving in the Patent Office. In the past year, according to Commissioner Robertson's figures, 142 of the 560 clerical workers have left the service. There are thirty clerks in the Patent Office who receive only $720 a year; under the new salary bill they would receive $1100.

The immense amount of work turned out yearly by the Patent Office was also shown by the Commissioner's statistics. The stock of the Office is about 75,000,000 copies of some 1,500,000 patents, and new patents at the rate of from 600 to 1000 a week add 50,000 more copies to be taken care of each week. There is a stenographic department handling legal work that turned out 13,000,000 words in the past year and brought $62,000 revenue.

Major Amasa M. Holcombe, formerly chief of Patent Section, General Staff, U.S.A., speaking at the same meeting, said that patents play an increasingly important part in proportion to the degree of specialization in industry. He stated that abuse of the patent laws is partly due to the failure of business men and engineers to appreciate and utilize patents. Both speakers urged that engineers aid the present patent legislation.

Mr. E. J. Prindle, chairman of the Patents Committee of the American Engineering Council, in a recent statement said that it was the unqualified opinion of the important engineering, research and manufacturing associations of the United States that the scientific and industrial interests of the country are being jeopardized by Patent Office conditions. The National Research Council, the American Chemical Society, and the National Association of Manufacturers were cited by him as among the organizations favoring Patent Office relief. "The European countries, taught by the war," he said, "are already strengthening their patent systems. America must not lag."

In connection with American patents in Europe, American Engineering Council announces the organization of a Foreign Relations Committee with L. B. Stillwell of New York as chairman. Discrimination against American patents in Europe ceased with the passage of the Nolan Treaty Patent Bill on March 3, and American inventors are therefore no longer at a disadvantage in foreign countries because of the lack of proper legislation.

American Engineering Council urges again that the engineers of the country support the pending patent legislation to increase salaries in the United States Patent Office.

Fred M. Feiker, vice-president and chairman of the editorial board of the McGraw-Hill Company, who has been active in the formation of the F.A.E.S. and of great assistance in the development of the plan for the elimination of waste in industry, has been appointed personal assistant to Secretary Hoover in the task of organizing and developing those branches of the Department of Commerce which relate directly to commerce and industry.

Alcohol as Automobile Fuel

It is stated in a recent issue of *Commerce Reports* that pure alcohol of from 41 to 42 degrees has been found to answer the requirements of automobile motors satisfactorily, with but a slight alteration in the carburetor and the substitution of metal floaters for the varnished cork floaters which are attacked by the alcohol. The amount of alcohol consumed is said to be practically the same as the amount of gasoline which would be consumed for the same work. A distinct advantage in the use of alcohol is that its combustion is much more complete, and therefore very little carbonized matter is deposited in the combustion chamber or ejected through the exhaust.

A Correction

In the May issue of Mechanical Engineering, page 351, reference was made to a paper on Developments in Organizing Personal Relationships in Industry presented at the March 25th meeting of the New York Section of the A.I.E.E. and the Metropolitan Section of the A.S.M.E. by Mr. L. P. Alford, editor of *Management Engineering*. Mr. E. W. Tree, associate editor of *Management Engineering*, whose name was inadvertently omitted, was co-author with Mr. Alford.

The A.E.S.C. Issues First Annual Report

IN THE form of an attractively printed pamphlet the American Engineering Standards Committee has just issued its first Annual Report outlining the Committee's progress during 1920.

Although the A.E.S.C. has been actively at work for only slightly more than a year, and much of the time and effort of the Committee has necessarily been spent in laying a basis for work the fruition of which will require at least two or three years, yet considerable progress has already been made in the unification of the more important standards and in overcoming the confusion that was being produced by the numerous organizations (more than 100) that hitherto published engineering standards without systematic coöperation among themselves.

Prior to December 31, 1920, there had been approved by the Committee "Tentative American Standard Specifications and Tests for Portland Cement," "Tentative American Standard Specifications for Fire Tests of Materials and Construction," and "American Standard Pipe Threads." Moreover, there had been submitted for approval by the Committee the "National Electrical Code" as an American Standard, and "Standard Test for Toughness of Rock," "Standard Method of Distillation of Bituminous Materials for Road Treatment," and "Standard Method of Sampling Coal," as Tentative American Standards, with the "Safety Code for Head and Eye Protection" submitted for approval as Recommended American Practice.

The Committee itself is now composed of 47 members representing 17 bodies or groups of bodies, including six national engineering societies, five governmental departments and 13 national industrial associations. As is generally known, its function is merely to see that each body or group interested in a standard shall have opportunity to participate in its formulation, which is in the hands of a working committee, technically called a "Sectional Committee." Each Sectional Committee is organized by, and under the leadership of, one or more of the principal bodies interested, such bodies being known as "Sponsors." Sponsorships have been arranged for the following projects under way by the beginning of this year:

Electrical Projects: Rating of Electrical Machinery; Term Markings for Electrical Apparatus

Mechanical Projects: Ball Bearings; Plain Limit Gages; Gears; Machine-Tool Elements; Nut and Bolt Heads; Pipe Flanges and Fittings; Screw Threads; Shafting

General Projects: Passenger and Freight Elevators; Color Scheme for Piping Installations; Steel Shapes; Zinc Ores and Zinc

Safety Codes: Aviation Safety Code; Construction Work; Electrical Fire Code; Electrical Safety Code; Floor Openings; Railings and Toe Boards; Foundries; Gas Safety Code; Grinding Wheels; Head and Eye Protection; Ladder Code; Lighting Code; Lightning Protection; Logging Operations and Sawmill Machinery; Machine Tools; Mechanical Transmission of Power; Paper and Pulp Mills; Electrical Power Control; Power Presses; Mechanical Refrigeration; Industrial Sanitation; Stairways, Fire Escapes and Other Exits; Textiles; Ventilation; and Woodworking Machinery.

As will be seen from the above lists, much of the Committee's attention is given to safety codes. Active work is now in progress on 24 such codes with hearty coöperation among the state commissions, associations of insurance companies, national engineering societies, manufacturers' and industrial associations, labor and civic organizations, and technical bureaus of the Federal Government. As is true of all work under the auspices of the American Engineering Standards Committee, such of the bodies as are interested in a particular code are represented in the committees responsible for the formulation of that code.

Copies of the report may be obtained on request to the American Engineering Standards Committee, 29 West 39th St., New York.

Japan Adopts the Metric System

In Comptes Rendus des Séances de l'Académie des Sciences for March 29, 1921, pages 795–796, reference is made to a telegram from Shirio Kikkawa, director of the Bureau of Weights and Measures of Tokyo, stating that in a recent session of the Japanese Parliament a law was passed making the use of the metric system obligatory in Japan. Since 1893 the metric system has been in "legal use" in Japan, but in practice its adoption has been greatly retarded by the prevalence of the local systems. The 1893 law giving the legal sanction to the metric system contained a series of suggestions and recommendations for the gradual substitution of the local units for the metric units. The new law makes the metric system compulsory in the Japanese Empire.

As regards other countries of the Far East, a provisional project for the obligatory adoption of the metric system was introduced in the Chinese Parliament in 1913 with a provision that the system would become officially the only system of measures in China within ten years, and similar projects have been enacted in Siam.

A.S.M.E. Presents Resolution of Thanks to Henry Hess

At a meeting of the Philadelphia Local Section held at the Philadelphia Engineers' Club on April 26, Henry Hess was presented with an engrossed copy of the following resolution of appreciation of the services rendered by him in the cause of standardization:

> The President and Council of The American Society of Mechanical Engineers by resolution gratefully acknowledge the service rendered to the cause of standardization by Henry Hess, who was one of the first to foresee the advantages that would accrue from the coöperation of manufacturers, consumers, and technical societies in standardization work, and who has been tireless in his efforts to bring about such coöperation in engineering standardization in this country.
>
> His foresight and devotion to the cause have been largely responsible for the broad principles now being followed by the American Engineering Standardization Committee, which is so successfully coördinating and directing the work of the various organizations engaged in engineering standardization.

Mr. Hess became a member of this Society in 1906. He was manager for the years 1911–1914 and vice-president for the period 1914–1916. He attended the meeting in person and received the resolution from D. Robert Yarnall, who made the presentation address.

Dr. Edward B. Rosa Dies

Dr. Edward Bennett Rosa, chief physicist of the United States Bureau of Standards, died suddenly in his office in the Bureau on May 17. Dr. Rosa had done notable work in the scientific field, particularly in electrical research. He was born in Rogersville, N. Y., on October 4, 1861. After graduation from Wesleyan University in 1886 he entered Johns Hopkins University where he later received the degree of Doctor of Philosophy. He served for short periods as instructor in the University of Wisconsin and as professor of physics at Wesleyan, and in 1901 became chief physicist of the Bureau of Standards.

Dr. Rosa developed the physical side of the respiration calorimeter and with Dr. Dorsey as collaborator in 1907 began work on the determination of the ampere which has now been perfected until it is possible to define this unit satisfactorily. His collection of known formulas for computing induction is known widely as a model. Another of Dr. Rosa's achievements was to establish definitely the laws governing electrolytic corrosion. During the war he developed a sound-ranging device for locating big guns, and the geophone for detecting mining operations. He also interested himself in the development of aircraft radio apparatus and improved the radio direction finders by which enemy ships and aircraft could be located. Under his direction the Bureau of Standards has established what is perhaps the finest radio research laboratory in the country.

He was a member of many scientific societies, among them being the International Commission of Electric Units and Standards, of which he was secretary, the National Academy of Sciences, the American Philosophical Society, the American Association for the Advancement of Science, the American Institute of Electrical Engineers, the American Physical Society, the Illuminating Engineering Society, the Société Française de Physique, the Washington Academy of Sciences, and the Philosophical Society of Washington.

NEWS OF OTHER SOCIETIES

Society of Industrial Engineers

Spring Meeting in Milwaukee on April 27, 28 and 29. Industrial leadership was the subject for discussion. The speakers emphasized the need for increasing attention to public matters in directing the affairs of industry. This was particularly stressed by L. W. Wallace, executive secretary of the American Engineering Council, who in his presidential address insisted that the industrial leader who does not concern himself with the social, political and economic life of his community is a failure. Turning to industrial problems in the United States, Mr. Wallace believed that the question of production should be considered as a whole rather than from the standpoint of the individual plant. He attributed the dissatisfaction of labor to the alternating phases in industry of intense activity and blighting stagnation. The antidote does not lie, he said, in an indiscriminate reduction of wages, but in regulating production and distribution economically.

Chester B. Lord, works manager, Advance-Rumely Co., Battle Creek, Mich., in Methods of Determining a Fair Day's Work and a Fair Day's Pay, related processes by which fatigue had been eliminated in his plant. In some experiments performed with a view to introducing rhythmic sequence, punch presses were taken which were used for blanking small armature disks continuously. The presses ran at 200 r.p.m. and had a 2-in. stroke. As the production of each press averaged between 35,000 and 40,000 pieces per day the man operating it had to stand on one foot or rest his weight on one side of his stool and trip a lever 35,000 times per day, moving his hands in synchronism. The stroke of one of the presses was reduced to $^3/_4$ in. and the speed coincidently lowered to 100 r.p.m. The result was that instead of from 80 to 85 blanks an average of 90 was secured per minute, noise and the wear and tear of the machine were sensibly reduced, and the efforts of the operator were diminished because he moved his work in rhythm with the press and no longer had to trip it. Similar studies were made of the operation of drill presses by women. In this instance the presses were altered so that the spindles would reciprocate automatically and in synchronism, and the speeds were adjusted to the requirements of the motion.

The educational requirements of a plant executive were discussed by S. E. Stout, betterment manager, Whiting Corporation, Harvey, Ill. The graduate, he said, should have had included in his schooling a definite class of industrial work, such as engineering, accounting, production, etc., which would prepare him for a definite class of positions; but no industry can expect colleges to train men for its own peculiar need. On the other hand, the graduate who knows a little of everything, but nothing in particular, is of no special value to any industry.

Standardization of products was urged both as an aid to production and as a necessary requirement to compete successfully with foreign manufacturers. Commenting on papers which treated this subject, President Wallace observed that whereas the national engineering societies of mechanical, electrical, mining and civil engineers are spending $50,000 a year for the working out of engineering standards in Europe, where a keen competition for industrial supremacy exists among the nations, the governments are appropriating hundreds of thousands of dollars for the same kind of research.

American Electrochemical Society

General meeting at Atlantic City, N. J., on April 21, 22 and 23. A symposium on corrosion and professional papers on electric arc welding, electric furnaces and electric-furnace problems in the steel and non-ferrous industries, and on electrolytic nickel were the technical arrangements of the program. Corrosion was discussed under four aspects: atmospheric corrosion; corrosion by water; chemical or acid corrosion; and electrochemical corrosion. Professor W. H. Walker, of the Massachusetts Institute of Technology, strongly advocated the corrosion-resisting ability of copper-bearing steel. The superior quality in this respect of pure commercial iron was maintained in a written discussion by J. A. Aupperle, chief chemist, American Rolling Mill Co., Middletown, Ohio. The argument for copper-bearing steel was supported by D. M. Buck, metallurgical engineer, American Sheet & Tin Plate Co., Pittsburgh, who presented additional evidence in confirmation of his theory that the alloy of copper and iron is less electropositive to the film of rust formed than is non-copper steel and the consequent decrease in difference of potential lessens the corrosion.

Practical Means of Preventing Corrosion of Iron and Steel Where Not Exposed Directly to the Atmosphere, was the title of a paper presented by F. N. Speller, metallurgical engineer, National Tube Co., Pittsburgh. Mr. Speller gave practical illustrations of "deactivating" apparatus for removing the oxygen in hot-water systems and spoke of the unusual beneficial results obtained. Boiler-tube corrosion was discussed by B. G. Worth, vice-president, Walter Kidde & Co., New York. Another paper by J. A. Aupperle and D. M. Strickland, both connected with the American Rolling Mill Co., Middletown, Ohio, dealt with acid corrosion. It presented a record of tests on pure iron made in open-hearth furnaces, copper iron, plain steel and copper steel to determine their resistance to corrosion by sulphuric acid. In all cases cited pure iron made in open-hearth furnaces had the smallest corrosion. A plea for the intelligent use of metallography and metallurgical principles in attempts to find non-corrodible alloys was made by Oliver P. Watts, associate professor of chemical engineering, University of Wisconsin, Madison, Wis.

Three papers were submitted treating of non-ferrous corrosion. In the first, Dr. John F. Thompson, manager technical department, International Nickel Co., enumerated the anti-corrosive properties of monel metal under varying conditions. Henry S. Rawdon, of the United States Bureau of Standards, discussed examples of interior corrosion of certain brasses, muntz metal particularly, where in many instances a dezincification takes place, resulting in a breaking down of the alloy. The third paper was on the Electrolytic Corrosion of Lead by Continuous and Periodic Currents, by E. R. Shepard, electrical engineer, United States Bureau of Standards.

Dr. Colin G. Fink, who acted as chairman at the sessions of the symposium, summarized the main points brought out. According to Dr. Fink the following facts were established: (1) That iron or steel containing about 0.25 per cent copper is anti-corrosive under most atmospheric conditions; (2) that iron or steel containing about 0.25 per cent copper when immersed in tap water or acidulated media does not endure as well as commercially pure iron; (3) oxygen in boiler or hot-water systems accelerates corrosion, but this influence is removable by extracting the oxygen; (4) corrosion is caused by carbon dioxide in boiler water containing soluble iron, but this condition can be corrected; (5) chromium, nickel and silicon added to iron tend to reduce corrosion; and (6) special steel and other alloys reduce corrosion possibilities, but a coördination of results is still lacking.

The list of professional papers on other subjects included the following: Phenomena of Arc Welding, by O. H. Eschholz; Electrodynamic Forces in Electric Furnaces, by Dr. Carl Hering; Recent Progress in High-Frequency Induction Heating, by E. F. Northrup; and Regulation of Electric Steel Arc Furnaces Using Movable Electrodes, by W. G. Mylins.

American Gear Manufacturers' Association

Convention at Cincinnati, on April 27–30. The reports from seven committees indicated that substantial progress has been made during the year in the standardization of gears. The Association and The American Society of Mechanical Engineers have been for some time working jointly for the formulation of standards which will be recognized as the United States standards. The recommendations of the various committees were discussed at great length and a number of them were adopted by the convention, while many others were referred back to the committees for further investigation. From the report of the spur-gear committee, for example, the following clauses were approved: The width of face for industrial spur gearing shall be 10 divided by the diametral pitch; the thickness of rim for spoked spur gears for industrial work shall be 4 divided by the diametral pitch, or 1.3 times the circular pitch; the diameter of hub for spoked spur gears for industrial work shall be 2 times the diameter of bore.

In a paper on The Ideal Chain and Sprocket Drive, G. M. Bartlett, Diamond Chain & Mfg. Co., Indianapolis, referred to the work of the committee on standardization of The American Society of Mechanical Engineers on steel roller chains, and that of the roller chain division of the Society of Automotive Engineers on the same subject. This work is now being done coöperatively by the two committees. British chain makers have also organized and have standardized to a great extent, and where differences occur they are not sufficiently great to prevent American chains from operating over British sprockets.

Erik Oberg, editor of *Machinery*, one of the committee of editors of technical magazines that recently conferred with Secretary Hoover of the Department of Commerce, conveyed the message from the secretary as to what the department aims to accomplish in the way of helping industry, and the assistance which it would like to secure from industrial associations in the way of furnishing statistics of the respective industries. The association went on record as favoring the assistance of the Department of Commerce as far as possible.

This report has been prepared from the extensive account of the convention published in *Iron Age* for May 5.

National Metal Trades Association

Annual meeting in New York on April 20 and 21. The belief was expressed that the worst of after-war industrial difficulties have passed, but complete recovery of business was not expected to take place this year. The outcome of recent conflicts between employers and union workers, it was thought, had demonstrated the soundness of the principle of the open shop.

A progress report was presented by the committee on industrial education. As a result of their studies during the year, the committee find that: (1) There is a shortage of efficient workers for normal production; (2) too few companies train workers; (3) many of those who do attempt to train have nothing even approximating a definite schedule for this work, and have not definitely determined responsibility for instruction and training as part of the duties of some person or group; (4) very few foremen are able to give proper instructions in the training necessary; (5) conditions within the various plants determine the type of training necessary. They offer the following recommendations: (1) That a definite number of specialists or apprentices be trained in each shop, this number to be proportionate to the total number employed; (2) that a committee on industrial education and training be formed in each branch, such committee to coöperate with local educational or training institutions on questions pertaining to technical, vocational, part-time and continuation schools, and to consider ways and means of furthering training and education within the plants of members of the association.

George A. Seyler, works manager, Lunkenheimer Co., related his experience in installing a training department. In planning and selecting a location the decision was reached to isolate the training department from the production departments. By this arrangement it was intended to prevent any confusion arising in the beginner's mind from comparing himself with trained workers. A director of training and several assistants are always on hand to give information and help to the apprentices. The training course lasts two weeks. As to how the students qualify in comparison with men trained under the old method, the foremen have reported that the students at the time of entering are equal to men who have been working in the shop from six to nine months.

The methods pursued by the University of Cincinnati in training instructor foremen were outlined by D. J. McDonald, professor of vocational education at that university. W. C. Wilson of the American Institute of Weights and Measures, New York, spoke briefly on the Britton bill, which was introduced in the House of Representatives on April 11 "to fix the metric system of weights and measures as the single standard of weights and measures for certain uses."

Further particulars of this meeting may be found in *Iron Age* for April 28.

LIBRARY NOTES AND BOOK REVIEWS

Aluminium. By George Mortimer. Sir Isaac Pitman & Sons, Ltd., London and New York. (Pitman's common commodities and industries.) Cloth, 5 × 7 in., 152 pp., illus., tables, $1.

This little book gives a clear description, suited to the needs of lay readers and business men, of the processes by which aluminium is made and of its uses in industry, particularly in automobile and aircraft construction, the chemical industry, electro and electrical engineering.

Cam Design and Manufacture. By F. B. Jacobs. D. Van Nostrand Co., New York, 1921. Cloth, 6 × 9 in., 121 pp., illus., $2.

This book is intended for machine designers and cam makers, as a practical aid in laying out and cutting cams. The writer has avoided mathematical formulas.

Chilton Tractor Index. Vol. 4, No. 1. Chilton Co., Philadelphia. 1921. Paper, 7 × 10 in., 456 pp., illus., tables, $2.

This semi-annual handbook is a reference book for those interested in tractors and farm-power machinery. It includes a directory of manufacturers of tractors, specifications of those on the market, with illustration, of most of them, a directory of manufacturers of farm-power machinery, electric plants, motor trucks, etc., and a list of makers of tractor parts and equipment. General articles and tables of data valuable to makers and users are also included.

Cost Accounting To Aid Production. By G. Charter Harrison. The Engineering Magazine Co., New York, 1921. Cloth, 6 × 9 in., 234 pp., plates, $7.50

The author of this volume believes that the customary methods of cost accounting are entirely unsuited to the needs of modern industry. Cost accounting, in his opinion, should not be a compilation of information concerning past events, but a method of predetermining costs. His book discusses the proper functions of an accounting system, and how to secure them, but is chiefly intended to stimulate thought and provoke discussion of the subject.

The Electrification of Railways. By H. F. Trewman. Sir Isaac Pitman & Sons, Ltd., London, 1920. (Pitman's technical primer series.) Boards, 4 × 7 in., 78 pp., diagrams, $1.

This little volume is an outcome of the discussions as to the advisability or otherwise of electrifying the railroads of Great Britian, a subject of general interest because of the necessity for relieving railway congestion and utilizing coal in the most economical manner. Without going into technical details covered in books on electric traction, the author brings forward the commercial aspect of the matter and calls attention to some of the main questions to which attention must be paid. Sufficient electrical information is given to enable these points to be understood by readers who are not electricians.

Élements de Mecanique Á L'usage des Ingenieurs: Resistance des Materiaux. By Robert d'Adhémar. Gauthier-Villars et Cie Paris, 1921. Paper, 6 × 9 in., 185 pp., diagrams.

In writing this book the author has attempted an introduction to the theory of the resistance of materials, in which the hypotheses that have been adopted to simplify the subject in practice are set forth as briefly and simply as is possible.

Ergebnisse der Aerodynamischen Versuchsanstalt zu Gottingen. By L. Prandtl. Part 1. R. Oldenbourg, München und Berlin, 1921. Paper, 8 × 11 in., 140 pp., plans, illus., tables, 40 marks.

This publication, the first of a series of bulletins devoted to the experimental investigations undertaken by this research laboratory, gives the hitherto unpublished results of recent researches. These are chiefly concerned with the shapes and profiles of propeller blades, although minor investigations of the reciprocal ef-

fect of wings and propellers and bodies and propellers and of the frictional resistance of wing fabrics are included. The bulletin gives results of tests of almost all the blade forms that have been used or investigated in Germany during recent years. The work also describes the organization, equipment and methods of the laboratory, and a summary introduction to the theory of air resistance, including the new theory of flight.

Fire Tests of Building Columns by Associated Factory Mutual Fire Insurance Companies, the National Board of Fire Underwriters, and the Bureau of Standards, jointly conducted at Underwriters' Laboratories, Chicago, 1917–1919. Cloth, 6 × 9 in., 388 pp., illus., charts, tables; $2.50.

This pamphlet presents the results of an investigation undertaken to ascertain the ultimate resistance against fire of protected and unprotected columns as used in the interior of buildings, and their resistance against impact and sudden cooling from hose streams when highly heated. The results of 91 fire and 15 fire and water tests are given, including tests of representative types of steel, cast iron, concrete-filled pipe and timber columns, protected and unprotected, and reinforced-concrete columns. It is stated to be the most complete investigation ever made.

Foundry Moulding Machines and Pattern Equipment. By Edwin S. Carman. Second edition. Cloth, 6 × 9 in., 225 pp., illus.

Contents: general moulding principles; the theory of jolt ramming; roll over jolt moulding machines; roll over jolt moulding machines for large-size, medium-size and small-size rolls; jolt moulding machines in brass and aluminum foundries; plain jolt moulding machines; air-operated squeezer machines; jolt stripper moulding machines; pattern equipment; flask equipment; machine moulded cores; foundations for jolt ramming moulding machines.

As shown by its contents, this book is intended to explain the construction of moulding machines and their use for various kinds of molds. The methods of pattern mounting and moulding are described in detail and very fully illustrated by photographs.

Gas Torch and Thermit Welding. By Ethan Viall. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 442 pp., illus., $4.

This is a careful summary of American practice and equipment, selected from the existing literature, from shop data, and from the experience of experts. The materials and apparatus used, the methods and their application to particular kinds of work, are described in detail, providing a large amount of practical information for workmen and engineers.

Gasoline Automobiles. By James A. Moyer. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 5 × 8 in., 261 pp., illus., $2.

The purpose of this book is to present clearly, briefly and interestingly, the essential principles of automobile construction. It is expected to furnish practical help to drivers who wish to know the causes of ordinary operating troubles and the ways to remedy them.

Herbert Hoover, the Man and His Work. By Vernon Kellogg. D. Appleton and Co., New York, 1920. Cloth, 5 × 8 in., 375 pp., portraits, $2.

Dr. Kellogg's book is the attempt of an observer, associate and friend to tell, simply and straightforwardly, the personal story of the man and his work up to the present. His boyhood, education, work in Australia, China and London are recounted briefly, and much space given to his work for the relief of Belgium, as food and relief administrator. As appendixes are given four important addresses by Mr. Hoover.

Human Engineering, a Study of the Management of Human Forces in Industry. By Eugene Wera. D. Appleton & Co., New York, 1921. Cloth, 5 × 8 in., 378 pp., $3.50.

This volume is a contribution to the discussion of the relationship of labor, capital and society in the industrial development of the world. Neither the old nor the modern school of management has succeeded in removing labor unrest, owing, in the author's opinion, to the ignoring of labor as a social group and disregard of the social purpose of industry. To present the principle of stimulating labor as a whole toward production at large for social purposes is the object of the present work.

The author studies the evolution of the ideas governing industrial relations, interprets the essentials of present issues, presents certain democratic tendencies and develops a typical organization for class coöperation. Other sections analyze the different psychological associations of men involved in industry, discuss the principles of human engineering and outline their application.

Marine and Stationary Engines. By A. H. Goldingham. Second edition, revised and enlarged. Spon and Chamberlain, New York, 1921. Cloth, 5 × 8 in., 233 pp., illus., plates, tables, $3.15.

This treatise is offered to designers and operators in need of concise, practical information on the various types and designs of Diesel engines. The book opens with a brief account of the theory of the engine. This is followed by a description of the details of construction, and discussions of indicator diagrams, of the advantages and disadvantages of Diesel engines, and of their operation and maintenance. These general topics are followed by descriptions and drawings of many types of engines.

The Mariners' Handbook. By International Correspondence Schools, Third edition. International Textbook Co., Scranton, Pa. 1920. Cloth. 4 × 5 in., 405 pp., plates, illus., $1.50.

A small pocketbook of information on nautical matters, intended for young men in the naval and merchant marine service, and for laymen interested in nautical affairs. Although the treatment is brief, it is sufficient for ordinary reference purposes.

Metallography. By Samuel L. Hoyt. Part 2, The Metals and Common Alloys. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth, 6 × 9 in., 462 pp., illus., tables, $5.

The second volume of this treatise on metallography describes the more important metals and alloys. This description includes the constitution and microstructure, the physical and mechanical properties for different heat and mechanical treatments, the effects of the common impurities and a brief discussion of the uses. Those compositions of particular importance have been treated in more detail and measured values of their important properties are included.

Modern Pulp and Paper Making. A Practical Treatise. By G. S. Witham, Sr. Book Dept., The Chemical Catalog Co., Inc., New York, 1920. Cloth, 6 × 9 in., 599 pp., illus., tables, $6.

This treatise is the work of a writer with long practical experience in the industry, and is intended to fill the need for a practical work on paper manufacture as carried on in America. It is not too abstruse and technical for the average papermaker, but is thorough enough to be of real value. The book describes the equipment and processes in actual use, and also treats of plant design and personnel.

Neue Grundlagen der Technischen Hydrodynamik. By L. W. Weil. R. Oldenbourg, Munich and Berlin, 1920. Paper, 6 × 9 in., 219 pp. illus., diagrams, 26 M.

This work is concerned with some of the problems of hydrodynamics, for which no exact elucidation or analytical solution has yet been obtained, as, for example, eddies in streams and pipes, the effect of expansions or contractions in channels, orifice problems, water hammer and the theory of turbines and of rotary flow of liquids. The author advances certain principles, based on long theoretical and practical study, which he considers correct and in accordance with experimental results.

The New Thermodynamics; the non-postulated rationale of motive power of heat. By Jacob T. Wainwright. Privately printed, 1921. Boards, 7 × 10 in., 44 pp.

Believing that the second law of thermodynamics, which is the foundation for present-day teaching of that branch of thermodynamics which treats of the motive power of heat, is untrue, the author presents his arguments for its repudiation. The monograph sets forth his views as to the rationale of the motive power of heat and his grounds for claiming that the Carnot principle conflicts with the principle of the conservation of energy and with observed results.

Patent Law. By John Barker Waite. Princeton University Press, Princeton, N. J., 1920. Cloth, 6 × 9 in., 316 pp., $5.

In this volume the professor of law in the University of Michigan Law School presents a concise but complete and thorough discussion and exposition of the principles of patent law, intended for inventors, engineers and all that class of laymen who from time

to time want information concerning their rights in respect to patents and inventions. It purports to cover only the substantive law of patents, their nature, validity, effect and their characteristics as property; and the author has attempted to present every issue that has come before the courts.

Patternmaking. By Ben Shaw and James Edgar. Sir Isaac Pitman & Sons, Ltd., London and New York, 1921. (Pitman's Technical Primer Series.) Boards, 4 × 7 in., 108 pp., illus., $1.

This little volume gives a birdseye view of the subject, for use by students, apprentices, young journeymen and others who wish some knowledge of the principles that underly it.

Producer Gas. By J. Emerson Dowson and A. T. Larter. Fourth edition. Longmans, Green and Co., New York, 1920. Cloth, 6 × 9 in., 361 pp., illus., $7.50

Contents: Theory of producer gas; furnace work; heating work; engine work; suction plants; gas from bituminous coal for engine work; producer gas from peat; gas traction on roads; gas propulsion of vessels; stand-by losses; comparison of gas and steam power; fuel; analysis of fuel and of producer gas; calorific power of solid and gaseous fuels; practical notes. Appendices.

The table of contents shows the scope of this treatise, which gives a general survey of present practice in the production and utilization of producer gas. This edition has been thoroughly revised.

Space and Time in Contemporary Physics; an Introduction to the Theory of Relativity and Gravitation. By Moritz Schlick. Rendered into English by Henry L. Brose. Oxford University Press, American Branch, New York, 1920. 10 + 89 pp., cloth, 6 × 9 in., $2.50.

The theory of relativity consists of two parts, the old special theory, and the more recent general theory. This book is intended as an introduction to the whole set of ideas contained in this theory and should interest especially those who are concerned with the general conceptions rather than the details. Its essential purpose is to describe these physical doctrines with particular reference to their philosophic significance. The present edition varies from the previous one only in minor improvements.

Taschenbuch fur Schiffsingenieure und Seemaschinisten. By E. Ludwig and E. Linder. Third edition. R. Oldenbourg, Munich and Berlin, 1920. Cloth, 5 × 7 in., 514 pp., tables, diagrams, illus., 24 M.

This book is a third edition, under a new title and with new compilers, of G. Bauer's Kalender für Seemaschinisten. In its present form it is a volume of convenient size, intended for marine engineers, and covering concisely all the mechanical equipment of ships. The volume contains the necessary physical and mathematical tables and formulas, sections on reciprocating steam engines, steam turbines, turbine reducing gear, boilers, boiler accessories, piping, combustion engines, auxiliary mechanical equipment, electrical equipment, measuring instruments, ship construction, navigation, laws and regulations. All these subjects are treated from a modern point of view, particular attention being given to methods likely to be used in the future.

Technischer Literaturkalender. Second edition. R. Oldenbourg, München-Berlin, 1920. Cloth, 6 × 8 in., 441 pp., frontispiece, 40 Marks.

This is a "Who's Who" of living German writers on technical subjects, compiled by the chief librarian of the German Patent Office. About seven thousand names are included. The information includes date of birth, address, education, occupation, writings and specialty. This edition contains a thousand names more than that of 1918, and has also an index by specialties and a list of deaths during 1918 and 1919.

The Testing of Motive-Power Engines. By R. Royds. Second edition. Longmans, Green and Co., New York, 1920. Cloth, 6 × 9 in., 392 pp. diagrams, tables, $7.50.

This book is intended for students with an elementary knowledge of motive-power engineering, who desire information on the practical testing of motive-power engines. Special attention is given to the variable conditions under which a plant may operate and the necessity for systematic arrangements where a series of trials is contemplated. This edition has been revised and modified to meet modern developments.

A Text Book of Chemical Engineering. By Edward Hart. The Chemical Publishing Co., Easton, Pa., 1920. Cloth, 6 × 9 in., 223 pp., illus., diagrams.

Contents: Materials; Location of Works; Boilers; Prime Movers; Plumbing; Crushing; Dissolving; Filtration; Tanks; Evaporation; Crystallization; Drying; Distillation; Absorption of Gases; Mixing and Kneading; Containers. The contents give an indication of the scope of Dr. Hart's new book, which is based upon his courses in Lafayette College. The treatment of the subject is brief and elementary, but thoroughly practical.

Text-Book of the Materials of Engineering. By Herbert T. Moore. With a chapter on concrete, by H. F. Gonnerman. Second edition, first impression. McGraw-Hill Book Co., Inc., New York, 1920. Cloth, 6 × 9 in., 327 pp., illus., charts, tables, $3.

This text-book contains a concise presentation of the physical properties of the common materials used in structures and machines, together with brief descriptions of their manufacture and fabrication. It is primarily intended for use in connection with courses on the mechanics of materials, but the author hopes that it will also be useful to draftsmen, inspectors, machinists and others who use these materials. In this edition the chapter on concrete has been rewritten, a chapter added on rubber, leather and hemp rope, and other sections have been enlarged or revised.

The Theory of Machines. By Robert F. McKay. Second edition. Edward Arnold, London, 1920. Cloth, 6 × 9 in., 448 pp., diagrams, $6.75.

Contents: Mechanics; Kinematics of Machines; Dynamics of Machines. Although many books exist which cover one or two special parts of this subject, the author believes this to be the first attempt at a systematic, comprehensive review of the whole. The volume is intended for students and engineers, many exercises being included for use by the former. This edition is practically identical with the first, only minor additions and alterations having been made.

The Ventilation Hand Book. By Charles L. Hibbard. Second edition, revised and enlarged. The Sheet Metal Publication Co., New York, 1920. Cloth, 6 × 8 in., 231 pp., illus., diagrams, $2.50.

This book is intended to present in convenient form, the principles of warm-air heating and ventilation, with simple methods for computing the sizes of the various parts of a system of this kind. The subject matter is arranged in the form of questions and answers, and the descriptions and mathematical data are given in very simple form.

The Welding Encyclopedia. Compiled and edited by L. B. Mackenzie and H. S. Card. Welding Engineer Publishing Co., New York, 1921. Cloth, 6 × 9 in., 224 pp., illus., $5.

This book is a collection of information on oxy-acetylene, electric and thermite welding, arranged in concise alphabetical form for ready reference. The material has been largely selected from the files of the *Welding Engineer*, and is practical rather than theoretical in character.

Winning the Public. By S. M. Kennedy. First edition. McGraw-Hill Book Co., Inc., New York, 1920. Cloth, 6 × 9 in., 168 pp., port., $2.50.

This volume includes the substances of various addresses delivered before technical and trade associations during recent years. They discuss the relations of public utilities with those whom they serve and the methods by which public confidence and good will can be secured.

THE ENGINEERING INDEX

(Registered U. S. Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Dust Explosions Dust Explosions, Cause, Effect and Prevention, David J. Price. Eng. News. Rec., vol. 86, no. 15, April 14, 1921, pp. 634–636, 6 figs. Ignition and propagation of flame. Changes in construction to prevent high pressures from being built up within heavy concrete wall construction.

AERIAL PHOTOGRAPHY

Cameras. Eastman Kodak Aerial Cameras. Flight, vol. 13, no. 10, Mar. 10, 1921, pp. 167–168, 7 figs. Automatic types

AERONAUTICS

Bureau of Naval Aeronautics. The Need of a Bureau of Naval Aeronautics. Aviation, vol. 10, no. 16, April 18, 1921, pp. 506–507. Suggests organization.

AEROPLANE ENGINES

B.M.W. The B.M.W. 6 Cyl. 185 Hp. Engine. Aviation, vol. 10, no. 12, Mar. 21, 1921, pp. 370–371, 1 fig. Characteristics: Number of cylinders, 6; bore, 5.906 in.; stroke, 7.086 in.; total piston displacement; 1,164.50 cu. in.

Constant-Compression. Aeroplane Engines Injecting Constant Mass of Fuel and Effecting Constant Compression at all Altitudes (Moteur d'aviation admettant une masse constante et effectuant une compression constant à toute altitude), M. A. Witz. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 11, Mar. 14, 1921, pp. 641–644. Possibilities of such motor for flight at high altitudes.

Developments. Army and Navy Development of Aero Engines. Aviation, vol. 10, no. 13, Mar. 28, 1921, pp. 390–391, 1 fig. Types of engines approved by Secretary of War and Secretary of Navy for development of army and navy air services.

Supercharging. The Calculated Performance of Airplanes Equipped with Supercharging Engines, E. C. Kemble. Nat. Advisory Committee for Aeronautics, report no. 101, 1921, 52 pp. 26 figs. Theoretical discussion of performance of aeroplane as affected by use of supercharging engine, together with comparative study of respective merits of different types of superchargers.

AEROPLANES

Caproni. Caproni's Latest Creation. Aeronautics, vol. 20, no. 388, Mar. 24, 1921, pp. 210, 2 figs. Flying boat with three triplane bodies. Specifications: Width, 33 meters, length, 24 meters: chord of wing, 275 meters, average speed, 140 km. per hr.; air endurance, 5–6 hr.

The Giant Caproni Tandem Triplane. Aerial Age, vol. 13, no. 5, April 11, 1921, pp. 103–104, 4 figs. Specifications: Power plant 8 Liberty 12-400 hp. engines; span, 100 ft.; length, 74 ft.; height, 31 ft. 6 in.; chord, 8 ft. 7 in.; empty, 30,000 lb.

Classification. Naming and Classifying Airplanes. Aviation, vol. 10, no. 13, Mar. 28, 1921, pp. 391. System adopted by Engineering Division of U. S. Army Air Service.

Design. The Extended Logarithmic Polar for the Calculation of Aeroplanes (Die erweiterte logarithmische Polare zur Flugzeugberechnung), Richard Vogt. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 5, Mar. 15, 1921, pp. 69–73, 7 figs. It is shown that by means of a simple extension of the Eiffel logarithmic polars for determination of relations between carrying capacity, speed, plane-surface area and engine power, general graphic charts can be developed, and simple examples are given to illustrate their use.

The Factors That Determine the Minimum Speed of an Aeroplane, F. H. Norton. Aerial Age, vol. 13, no. 3, Mar. 28, 1921, pp. 57–60, 6 figs. It is computed that wing section affects minimum speed 26 per cent; aspect ratio, 4 per cent; gap chord ratio, 4 per cent; longitudinal control, 20 per cent; lateral control, 15 per cent; power in level flight, 5 per cent; vertical component of air screw thrust, 3 per cent; stagger, 2 per cent; scale, 2 per cent; and slip-stream on wings, 1 per cent.

German. German Aerial Developments, Erik Hildesheim. Aeronautics, vol. 20, no. 388, Mar. 24, 1921, pp. 198–200, 4 figs. Survey of types of aeroplanes under construction in German works.

ALLOY STEELS

Burrowlite. Imparts Odd Properties to Steel. Iron Trade Rev., vol. 68, no. 14, April 7, 1921, pp. 974–975, 1 fig. Alloy discovered by Dr. L. P. Burrowlite while experimenting with nickel ores. It is made from nickeliferous ore obtained in Sudbury district of Ontario. Alloy gives steel property of machinability even when showing qualities of extreme hardness.

ALLOYS

Ternary. Coefficients of Equivalence in Ternary Alloys, Léon Guillet and Albert Portevin. Chem. & Metallurgical Eng., vol. 24, no. 14, April 6, 1921, pp. 609–612, 4 figs. General discussion of effect of adding little of third element to binary alloy. Mathematical development of equations defining isomicrographic lines, and boundaries of zones showing two well-defined constituents. (Abstract.) Translated from Revue de Métallurgie.

AMMONIA

Synthesis. Some Interpretations of the Ammonia Synthesis Equilibrium, R. S. Tour. Jl. Indus. & Eng. Chem., vol. 13, no. 4, April 1921, pp. 298–300, 3 figs. Curves showing effect on equilibrium of ammonia content of variation of any one of conditions involved when others are held at arbitrary values.

AMMONIA COMPRESSORS

Apeldoorn. Apeldoorn Ammonia Compressors and the Apeldoorn Two-Pressure Evaporator System of Refrigeration. Practical Engr., vol. 63, no. 1777, Mar. 17, 1921, pp. 164–168, 7 figs. Double-acting horizontal compressors with multiple-opening disk valves in cylinder body.

Rod Packing. Ammonia Compressor-Rod Packing, W. H. Motz. Power, vol. 53, no. 14, April 5, 1921,

pp. 543–545, 4 figs. Comparative value of different types of packing.

APPRENTICES, TRAINING OF

Machine Industry. Training Men for the Machine Industry, Erik Oberg. Machy. (N.Y.), vol. 27, no. 8, April 1921, pp. 779–782, 6 figs. Organization of educational and training departments established by Norton Co., Worcester, Mass., with view to qualifying men for various classes of occupations in machine industry.

National Apprenticeship Council. Apprenticeship Plan Drawn Up by Joint Conference Board. Contract Rec., vol. 35, no. 14, April 6, 1921, pp. 336–339. Formation of National Apprenticeship Council governing local councils is suggested. Apprenticeship agreement enforces employers to provide time for education along technical lines.

ASHES

Weight of Conical Pile. The Weight of a Conical Pile of Ashes, N. G. Near. Power Plant Eng., vol. 25, no. 8, April 15, 1921, p. 418, 1 fig. Chart giving weight of conical pile of ashes.

AUTOMOBILE ENGINES

Assembling. Methods of Motor Assembly. Am. Mach., vol. 54, no. 15, April 14, 1921, pp. 641–645, 14 figs. Practice in assembling of Essex motor.

Gray-Beall. New Four-Cylinder Engine to be a Stock Product, J. Edward Schipper. Automotive Industries, vol. 44, no. 13, Mar. 31, 1921, pp. 694–695, 2 figs. Gray-Beall $3^1/_2$ by 5 in. four-cylinder overhead-valve engine.

High-Speed. High-Speed Engines of Small Piston Displacement, Louis Chevrolet and C. W. Van Ranst. Jl. Soc. Automotive Engrgs., vol. 8, no. 4, April 1921, pp. 368–374, 8 figs. Racing engine designed by Frontenac Motor Co., Indianapolis.

Oldsmobile. To Produce New Eight-Cylinder Engine for Use in Oldsmobile Chassis, J. Edward Schipper. Automotive Industries, vol. 44, no. 12, Mar. 24, 1921, pp. 642–646, 7 figs. Engine will be produced in quantity, using new tool equipment especially designed for purpose. Cylinders will have rolled finish in place of ground surface. Blocks and beads to be interchangeable. Pressure lubrication and high speed, two-bearing crankshaft among features.

Starters. Instantaneous Current and Voltage Values in Battery, G. W. Vinal and C. L. Snyder. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 319–327 and 364, 17 figs. Experiments conducted at Bur. of Standards to determine effects of temperature, compression, lubrication, distributor action and flywheel velocity upon operation on starter system.

Turmo. A New Four-Cylinder Engine of Conventional Design, J. Edward Schipper. Automotive Industries, vol. 44, no. 15, April 14, 1921, pp. 800–802, 5 figs. Turmo engine intended for passenger car or light truck applications. Four $3^1/_4$ by 5-in. cylinders develop maximum of 47 hp. at 2200 r.p.m. Full pressure-feed lubrication and ample water-jacket space are provided.

AUTOMOBILE FUELS

Alcohol. Forest Products as Motor Fuels, E. C. Scherrard. Sci. Lubrication, vol. 1, no. 2, Feb. 1921, pp. 8–13 and 25. Possibilities of ethyl alcohol as susbtitute for gasoline or as auxiliary for blending purposes.

Progress in Tests of Alcohol as Fuel. Power Wagon, no. 197, April 1921, p. 20. Report of British Empire Motor Fuels Committee.

The Carburetion of Alcohol, A. W. Scarratt. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 328–330, 2 figs. Characteristic curves of four-cylinder engine equipped with special hot-spot manifold for burning alcohol.

Benzol. Benzol for Motor Fuel. Gas & Oil Power, vol. 16, no. 186, Mar. 3, 1921, p. 84. Specifications of British Eng. Standards Assn. Benzol is defined as mixture of benzene and not more than 30 per cent by volume of toluene and xylenes.

Kerosene. Utilization of Kerosene as Automobile Fuel(L'emploi des pétroles lampants dans les moteurs d'automobiles), A. Grebel. Génie Civil, vol. 78, no. 14, April 2, 1921, pp. 289–295. Technical study of carburetion of kerosene and account of experiments conducted at Schneider works in France.

Natalite. Data Concerning the Advantages, Production, and Cost of "Natalite" Motor Fuel. Int. Sugar Jl., vol. 23, no. 267, Mar. 1921, pp. 147–153, 2 figs. Mixture consisting of 55 per cent alcohol, 44.9 per cent ether, and 0.1 per cent ammonia. (To be continued.)

Palm Oil. Palm Oil as Engine Fuel. Gas & Oil Power, vol. 16, no. 186, Mar. 3, 1921, pp. 85–86. Tests in Brussels with palm oil and other vegetable oils grown in Belgian Congo.

Research. Motor Fuel. So. African Eng., vol. 32, no. 3, Mar. 31, 1921, pp. 55–56. Research on utilization of gasoline substitutes as automobile fuels. Report of Empire Motor Fuels Committee of Imperial Motor Transport Council.

Semi-Water Gas. Utilization of Water Gas as Automobile Fuel (Utilisation du gaz pauvre a l'alimentation des moteurs d'automobiles), E. H. Lemonon. Nature (Paris), no. 2445, Feb. 12, 1921, pp. 105–112, 10 figs. Records of experiments. Apparatus used for operating Ford car by means of gas.

AUTOMOBILES

Carburetors. See CARBURETORS.

Clutch and Gear-Box Design. Developments in Transmission, S. Bramley-Moore. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 350–364, 25 figs. Developments in clutch and gear box design which have been suggested with a view to reducing cost of upkeep.

Drive Gears. Gears for Motor Transmissions, Fred H. Colvin. Am. Mach., vol. 54 no. 14, April 7, 1921, pp. 606–609, 14 figs. Machining and assembling operations.

Research. Much Useful Automotive Research in Progress at Bureau of Standards, Herbert Chase. Automotive Industries, vol. 44, no. 14, April 7, 1921, pp. 750–755, 7 figs. Work now proceeding includes tests of brake linings made with view to standardizing apparatus for this purpose, efficiency and endurance tests of truck axles, study of flame propagation and detonation phenomena, and test of lubricants intended to determine definitely what physical characteristics render oil best suited for use in automotive engines.

Transmission Units. Methods Used by Transmission Specialists. Fred H. Colvin. Am. Mach., vol. 54, no. 13, Mar. 31, 1921, pp. 537–540, 12 figs. Frame-case and bell-case types of transmission. Machining operations on two types. Special tools, fixtures and methods for economical production.

AVIATION

Aerial Transportation. Aerial Transportation as a Business Proposition, Glenn L. Martin. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 347–349. Reliability of air transportation. Survey of developments of commercial transportation.

Airplane Efficiency in Public Transportation, H. White Smith. Aviation, vol. 10, no. 16, April 18, 1921, pp. 498–501, 3 figs. Records of European commercial services. Paper read at Efficiency Exhibition, London.

Canadian Air Progress—1920. Aviation, vol. 10, no. 12, Mar. 21, 1921, pp. 372–375.

Commercial Future of Aviation (L'avenir commercial de l'aviation), M. Maurice Duval. Ingenieur, vol. 36, no. 11, Mar. 12, 1921, pp. 199–203. Economical advantage of aerial transportation.

Cloudy Weather. Aerial Navigation in Cloudy Weather (La navigation aérienne par temps de brume), M. de Gramont de Guiche. Aérophile, vol. 29, nos. 3 and 4, Feb. 1–15, 1921, pp. 42–45, 3 figs. Technical study. Report submitted to French commission of aerial transportation.

Commercial. Commercial Aviation in Germany, W. Wronsky. Aviation, vol. 10, no. 13, Mar. 28, 1921, pp. 402–403, 1 fig. Possibilities of developments. Translated from Der Luftweg.

The Next Steps in Commercial Aviation, Jesse J. Vincent. Flying, vol. 10, no. 3, April 1921, pp. 87–90, 3 figs. Visualizes probable future developments in design of aeroplanes for commercial purposes.

Customs Regulations. French Aircraft Customs Regulations. Aviation, vol. 10, no. 13, Mar. 28, 1921, pp. 392–393. Regulations and customs formalities to be applied to all aircraft entering or leaving France.

Flight Tests. Accelerations in Flight, F. H. Norton and E. T. Allen. Nat. Advisory Committee for Aeronautics, no. 99, 1921, 8 pp., 34 figs. Tests at Langley Field station conducted to obtain magnitude of load factors in flight and to procure information on behavior of airplane in various maneuvers.

Military. Angles of Attack and Air Speeds During Maneuvers, E. P. Warner and F. H. Norton. Nat. Advisory Committee for Aeronautics, no. 105, 1921, 12 pp., 9 figs. Experiments on direct measurement of angles of attack during maneuvers.

Soaring Flight. Dr. Nimführ's Solution of the Soaring Flight Problem, Alfred Gradenwitz. Aeronautics, vol. 20, no. 388, Mar. 24, 1921, pp. 203–204. Automatic stabilizer for aeroplanes.

Sailing Flight, R. DeVillamil. Aeronautics, vol. 20, no. 387, Mar. 17, 1921, pp. 180–181, 4 figs. Mechanics of soaring flight.

The Characteristics of Soaring Flight (Segelflugwesen), E. Rumpler. Zeit. für Flugtechnik u. Motorluftschiffahrt, vol. 12, no. 4, Feb. 28, 1921, pp. 50–53. Discusses expediency of different types of soaring airplanes, especially those figuring in the Rhön soaring-flight contest: and recommends that the study of soaring flight should replace that of gliding.

AVIATORS

Tests. Intelligence Tests at High Altitudes, Alfred Gradenwitz. Aeronautics, vol. 20, no. 389, Mar. 31, 1921, pp. 221–222, 3 figs. Results of intelligence tests in diluted air.

B

BALANCING

Machine Members. Loss of Energy through Unbalance in Rapidly Rotating Machine Parts (Energieverlust durch Unbalanz), Hans Heymann. Betrieb, vol. 3, no. 13, Mar. 25, 1921, pp. 363–366, 9 figs. Study of such sources of errors in the mass distribution of a rotating machine part as interfere with the smooth running of the body during operation of machine.

BALLOONS

Pilot. The Rate of Ascent of Pilot Balloons, B. J. Sherry. U. S. Dept. of Agriculture, Monthly Weather Rev., vol. 48, no. 12, Dec. 1920, pp. 692–694, 1 fig. Factors controlling rate of ascent of pilot balloons. Records of experiments.

Predetermination of Form. Predetermination of the Form of an Inflated Balloon (Prédetermination de la forme d'un ballon gonflé). Technique automobile et Aerienne, vol. 12, no. 112, 1921, pp. 11–14, 3 figs. Graphical study of forces acting within envelope of non-rigid dirigible balloon.

BEAMS

Buckling of. Flexural Buckling, Albert E. Guy. Army Ordnance, vol. 1, no. 5, March-April 1921, 256–261, 15 figs. Laws of buckling of cantilever beams on uniform rectangular sections.

Reinforced-Concrete. Effect of Repeated Reversals of Stress on Double-Reinforced Concrete Beams, W. A. Slater, G. A. Smith and H. P. Mueller. U. S. Dept. of Commerce, Technologic Papers, Bur. of Standards, no. 182, Dec. 20, 1921, 51 pp., 33 figs. For all of beams tested failure was by tension in steel. Generally beams in which highest stresses were developed in test withstood smaller number of repetitions of load than those in which measured stresses were smaller.

Torsion on Rectangular Cross-Sections, C. R. Young. Can. Engr., vol. 40, no. 12, Mar. 24, 1921, pp. 315–318, 2 figs. Formulas for determining stresses in beams of rectangular section. Method of reinforcing concrete beams for torsion.

BEARINGS, BALL

Lubrication. Requirements for Ball Bearing Lubrication, J. B. Castino. Sci. Lubrication, vol. 1, no. 2, Feb. 1921, pp. 18–19 and 31, 4 figs. Specifications for greases and oils.

BENZOL

Uses. Benzole—Its Recovery, Rectification, and Uses. Gas Jl., vol. 153, no. 3008, Jan. 5, 1921, pp. 31–33. Review of book by S. E. Whitehead published by Benn Bros., London.

[See also AUTOMOBILE FUELS, Benzol.]

BLAST-FURNACE GAS

Dust Recovery. Blast-Furnace Flue Dust Recovery, George B. Cramp. Iron Age, vol. 107, no. 12, Mar. 24, 1921, pp. 775–778, 1 fig. Automatic apparatus for wet recovery of flue dust.

Handling Flue Dust Economically, George B. Cramp. Iron Trade Rev., vol. 68, no. 12, Mar. 24, 1921, pp. 836–839, 1 fig. Plan for recovery of blast-furnace flue dust and charging it in form of sludge into top of stack.

BLASTING

Liquid-Oxygen. Blasting with Liquid Oxygen, S. P. Cortland. Sci. Am. Monthly, vol. 3, no. 4, April 1921, pp. 333–336, 6 figs. Equipment and procedure.

BOILER EXPLOSIONS

Abo, Finland. Steam-Boiler Explosion in the Abo Electrical Works (Finland) (Dampfkesselexplosion im Elektrizitätswerk Abo), M. Klein. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 11, Mar. 12, 1921, pp. 266–267, 3 figs. Account of explosion and results. Action of difference of temperature in the shell plates of upper boiler. Similarity of explosion to that in the central power plant Franken in Nuremburg, Germany.

BOILER FEEDWATER

Treatment. Economic Production of Distilled Water for Steam Central Stations (Production économique de l'eau distillée pour les centrales thermiques), M. J. Leleu. Chaleur & Industrie, vol. 2, no. 2, Feb. 1921, pp. 75–78, 4 figs. Triple-effect distiller operated by exhaust steam from pumps or turbine.

BOILER INSPECTION

National Board of Boiler Inspectors. Constitution and By-Laws of National Board of Boiler Inspectors. Boiler Maker, vol. 21, no. 4, April 1921, pp. 107–109. Object of association is to promote uniformity of construction and inspection of boilers in U. S.

Regulations. Regulations for Inspection of Railway Steam Boilers, other than Locomotive Boilers. Can. Ry. & Mar. World, no. 278, April 1921, p. 179. General order passed on Feb. 16, 1921, by Board of Ry. Commissioners for Canada.

BOILER OPERATION

Combustion. Heating Value in Connection with Steam-Boiler Investigations (Der Heizwert bei Dampfkesseluntersuchungen), H. Hilliger. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 11, Mar. 12, 1921, pp. 270–272, 4 figs. Notes on quantity of saturated vapor in combustion gases: importance of the separation of water from the combustion gases for operation and boiler efficiency; consideration of higher heating value in tests.

Instruments. Boiler Operation at the Power Plant of the Mesta Machine Company, C. Fischer. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 239–247, 9 figs. Installation of mechanical devices and instruments.

BOILERS

Electrically Heated. Bergeon-Frédet Electric Boiler (Le générateur de vapeur "Bergeon-Frédet" à chauffage électrique). Houille Blanche, vol. 20, nos. 49 and 50, Jan.-Feb. 1921, pp. 24–25, 3 figs. Three-phase current of 50 periods is applied at pressure of 6500 volts.

Heat Transmission. Tests on Heat Transmission in Steam Boilers (Considération sur la transmission de la chaleur dans les générateurs de vapeur dé-

duites d'essais de vaporisation), Victor Kammerer. Bulletin de la Société Industrielle de Mulhouse, vol. 86, no. 8, Nov. 1920, pp. 519-582, 10 figs. Experiments on water-tube boiler. Empirical equations are constructed from results found.

Marine. See MARINE BOILERS.

Sectional. Sectional Boilers Composed of Sections Connected in Series and Surrounding the Feeding Chute and a New Device for Testing the Feeding Chute [Gliederkessel aus hintereinander geschalten den Füllschacht umschliessenden Gliedern und Füllschacht-Prüfungseinsatz (D.R.P.)]. Gesundheits-Ingenieur, vol. 44, no. 12, Mar. 19, 1921, pp. 134-135, 4 figs. Describes new patented device.

BOILERS, WATER-TUBE

Marine. Advantages of the Use of the Water-Tube Boiler in the Mercantile Marine, James Kemnal. Trans. North-East Coast Instn. Engrs. & Shipbuilders, vol. 37, part 4, Feb. 1921, pp. 185-192 and (discussion), pp. 193-208, 8 figs, partly on 3 supp. plates. Chief advantages claimed for water-tube boiler over cylindrical boiler are greater safety, possibility of using higher pressures and saving in weight.

BRAKES

Train, Automatic. Successful Test of the Automatic Straight Air Brake on the Norfolk & Western Railway. Ry. & Locomotive Eng., vol. 34, no. 4, April 1921, pp. 91-98, 12 figs.

Train, Tests. Handling 9,000 Tons Down a 1.6 per cent Grade. Ry. Rev., vol. 68, no. 14, April 2, 1921, pp. 515-521, 9 figs. Tests conducted by Norfolk & Western on control of 70-car train with automatic straight air brakes.

BRASS

Aluminum in. Influence of Small Quantities of Aluminum Upon the Properties of Brass, J. Czochralski. Brass World, vol. 17, no. 3, Mar. 1921, p. 64. Tests showed that aluminum content greater than about 0.06 per cent exerts injurious influence upon brass.

BROACHES

Burnishing. Burnishing Broaches, E. A. Dixie. Am. Mach., vol. 54, no. 14, April 7, 1921, pp. 599-601, 8 figs. How to make and use broaches. Kinds of spoiled work that may be reclaimed by their use. Turning broached work with diamond.

BROACHING

Keyways. Guide Bushings for Keyway Broaching, Carl H. Briggs. Machy. (N.Y.), vol. 27, no. 8, April 1921, pp. 767-769, 4 figs. Formulas for designing bushings for broaching accurate keyways.

BUILDING CONSTRUCTION

Electric Welding in. Electrically-Welded Structural Steelwork. Engineering, vol. 121, no. 2881, Mar. 18, 1921, pp. 323, 3 figs. Welding used for extension of foundry building.

BULKHEADS

Deflections. Notes on Deflections of Bulkheads and of Ships, A. M. Robb. Engineering, vol. 111, no. 2883, April 1, 1921, pp. 407-410, 21 figs. Application of theory of beams to investigation of bulkhead stiffening.

Spacing. On the Spacing of Transverse Bulkheads, K. G. Finlay. Engineering, vol. 111, no. 2883, April 1, 1921, pp. 403-405, 6 figs. Scheme for determining subdivisions of bulkheads.

BUSES

London. Motor Omnibus for the London General Omnibus Company, Limited. Engineering, vol. 111, no. 2883, April 1, 1921, pp. 391-392, 9 figs. partly on supp. plate. Double deck buses with total seating capacity of 54 passengers.

C

CALCULATING MACHINES

Manufacture. Calculating Machines. Times Eng. Supp., no. 557, Mar. 1921, p. 99. Principles involved in manufacture of machines for performing divisions and extracting square roots automatically.

CAMS

Design. Calculation of Inertia Forces in Mechanisms Operated by Cams (Calcul des efforts d'inertie dans les mécanismes commandés par des cames) P. Cayére. Arts et Métiers, vol. 74, no. 4, Jan. 1921, pp. 28-30, 6 figs. Construction of acceleration graphs for typical mechanisms.

Manufacture. Production of Accurate Cams, E. A. Dixie. Am. Mach., vol 54, no. 13, Mar. 31, 1921, pp. 553-556, 15 figs. Fixtures employed in manufacture of typical cams.

CAR AXLES

Manufacture. The Manufacture of Railway Axles Ry. Engr., vol. 42, no. 494, Mar. 1921, pp. 85-87, 4 figs. Special machinery and equipment developed by British manufacturers.

CAR CONSTRUCTION

Support on Trucks. New Type of Support of a Railway Car on Trucks (Nouveau type de suspension pour voiture a bogies), M. Lehoucher. Revue générale des Chemins de Fer, vol. 39, no. 12, Dec. 1920, pp. 271-294, 28 figs. Method developed by French Southern Ry. Springs possessing variable flexibility and having no friction between their elements. Records of service of cars fitted with system.

CAR COUPLINGS

Automatic. Automatic Couplings for Railway Rolling-Stock. Ry. Engr., vol. 42, no. 495, April 1921, pp. 135-136, 4 figs. Automatic coupling on railways and terminals systems in Switzerland.

The Boonzaier Automatic Coupling. Ry. Engr., vol. 42, no. 495, April 1921, p. 129, 3 figs.

CAR WHEELS

Chilled Iron. Manufacture, Properties and Uses of Chilled Iron Wheels (Les roues en fonte trempée, leur fabrication, propriétés et usages), M. E. Polushkin. Revue de Métallurgie, vol. 18, no. 1, Jan. 1921, pp. 143-57, 10 figs. Heat-treating process. Interpretation of photomicrographs. Bibliography. (Concluded.)

CARBOCOAL

See FUELS, Carbocoal.

CARBURETORS

Manifolds, Vaporizing in. Vaporising in the Manifold, Robert W. A. Brewer. Autocar, vol. 46, no. 1324, Mar. 5, 1921, pp. 429-431, 7 figs. Study of conditions of carburation and of correct methods of insuring vaporization of fuel.

CARS, FREIGHT

Container System. Container System Extended on the New York Central. Ry. Rev., vol. 68, no. 16, April 16, 1921, pp. 600-602, 4 figs. Container system was first operated for express car and is now being extended to freight service.

Draft-Gear Tests. Draft-Gear Tests of the Railroad Administration. Ry. Mech. Engr., vol. 95, no. 4, April 1921, pp. 229-232, 4 figs. Investigations conducted by inspection and test section of Baltimore & Ohio Railroad.

Gondola. New Norfolk & Western 100-Ton Coal Cars, John A. Pilcher. Ry. Age, vol. 70, no. 15, April 15, 1921, pp. 923-928, 9 figs. Body supported on side bearings instead of center plate. New type six-wheel truck.

CARS, PASSENGER

Steel. Safety of Passengers in Steel Cars, Frank M. Brinkerhoff. Official Proc. New York Railroad Club, vol. 31, no. 5, Mar. 18, 1921, pp. 6399-6413 and (discussion) pp. 6413-6433, 12 figs. Suggests protection of steel cars with special arrangement of cable loops at ends, to prevent telescoping in accidents.

The Safety of Passengers in Steel Railway Cars, Frank M. Brinckerhoff. Ry. Mech. Engr., vol. 95, no. 4, April 1921, pp. 223-227, 8 figs. Also in Ry. Age, vol. 70, no. 12, Mar. 25, 1921, pp. 781-785, 8 figs. Discussion of action of cars in accidents and methods which will avoid telescoping. Paper read before New York Railroad Club.

The Steel Passenger Cars of the Prussian-Hessian State Railroad (Die eisernen Personenwagen der preussisch-hessischen Staatsbahnen), H. Speer. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 11 and 12, Mar. 12 and 19, 1921, pp. 261-265 and 295-297, 15 figs. Objections to steel cars with regard to rusting, loosening of parts, influence of heat and use of material are said not to be justified; the consumption of ore is offset by the saving effected in coal with the operation of the lighter-weight steel cars. Economy in construction and maintenance is set forth.

CAST IRON

Filtering. The Filtering of Cast Iron (Le filtrage de la fonte), D. Mathu. Fonderie Moderne, no. 1, Jan. 1921, pp. 9-16, 15 figs. Brunelli process for filtering cast iron by pouring it through special funnel which removes impurities.

Nickel, Influence on. Influence of Nickel on Cast Iron. Automotive Industries, vol. 44, no. 13, Mar. 31, 1921, pp. 705. Results of tests on cast iron with nickel and cobalt additions. Addition of one per cent nickel increased compressive and transverse strength 30 per cent while tensile strength increased 25 per cent and hardness 18 per cent. Effect of cobalt is reverse of that of nickel, except in respect to hardness.

CASTINGS

Centrifugal. Centrifugal Castings. Engineering, vol. 121, no. 2881, Mar. 18, 1921, pp. 311-312, 6 figs. Methods and machines employed for casting cylindrical articles under centrifugal pressure at works of Stokes Castings, Ltd., Mansfield, England.

Cleaning. Cleaning and Dressing Castings, F. W. Wilson. Foundry Trade Jl., vol. 23, no. 239, Mar. 17, 1921, pp. 243-246, 4 figs. Cleaning chamber for intricate castings. Paper read before Manchester Assn. Engrs.

Cleaning and Dressing Castings—II, F. W. Wilson, Machy. (Lond.), vol. 18, no. 443, Mar. 24, 1921, pp. 775-777, 4 figs. Details of sand-blasting apparatus.

CEMENT

Analysis. Chemical Analyses of Cement as Indicators of Behavior. Eng. News-Rec., vol. 86, no. 15, April 14, 1921, pp. 637-639, 2 figs. Rearrangement of stock analyses recommended so as to show true content of active agents.

Slabs. New Design Data for Cement Slabs. Am. Architect, vol. 119, no. 2359, Mar. 9, 1921, pp. 287-291, 10 figs. Tests at Lehigh University on slabs poured with mixture under pressure from nozzle.

CEMENT GUN

Uses. The Application of Cement Mixtures by Machinery, George J. Young. Eng. & Min. Jl., vol. 111, no. 13, Mar. 26, 1921, pp. 537-543, 6 figs. Summary of properties and examples of use of gunite in mining and metallurgical industry. Fireproofing of underground timber and surface structures. Prevention of slabbing by sealing rock surfaces and obviating action by air and moisture.

CEMENT, PORTLAND

Cal, Effect of. Effect of Cal in Portland Cement. Public Works, vol. 50, no. 14, April 2, 1921, pp. 278-279. Result of investigation by Bur. of Standards indicates acceleration of setting without reduction of ultimate strength.

Testing. Japanese Standard Rules for Testing Portland Cement. Eng. World, vol. 18, no. 4, April 1921, pp. 273-274. Issued by Dept. of Agriculture and Commerce on Feb. 10, 1905, revised Dec. 10, 1909, and June 20, 1919. Translated by Japan Portland Cement Assn.

Portland Cement, R. E. Stradling. Concrete & Constructional Eng., vol. 16, no. 3, Mar. 1921, pp. 169-177, 13 figs. Comparative study of British and foreign standards and methods of testing portland cement. (To be concluded.)

CENTRAL STATIONS

Electric-Furnace Operation. Electric Furnaces and Central Station Charges, H. O. Swoboda. Forging & Heat Treating, vol. 7, no. 3, Mar. 1921, pp. 190-193, 3 figs. Curves illustrating decrease of cost of electric energy with increasing load factor for various maximum demands. Comparison of electric-station load in industrial districts with and without electric furnace.

Mine-Mouth. A Mine-Mouth Super-Power Station. Power, vol. 53, no. 14, April 5, 1921, pp. 532-542, 22 figs. Total capacity is to be 300,000 kw., in units of 60,000 kw. Power is generated at 12,000 volts and is stepped up to 66,000 volts through bank of three 23,600-kva. transformers in power house. Station is located near coal mine about 50 miles from Pittsburgh.

Colfax Power Station of the Duquesne Light Company, Pittsburgh, D. L. Galusha and C. W. E. Clarke. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 4, April 1921, pp. 281-294, 44 figs. Installation of two 60,000-kw. units first step in proposed 300,000 kw. power station for Pittsburgh district.

Reliability and Simplicity—Characteristics of New Colfax Station. Elec. World, vol. 77, no. 16, April 16, 1921, pp. 865-872, 19 figs. Generating station of Duquesne Light Co., designed for ultimate rating of 300,000 kw. Groups of six moderately rated stations under one roof operating in parallel on duplicate high-tension buses.

Colfax—A Superpower Plant at the Mouth of a Coal Mine. Elec. World, vol. 77, no. 14, April 2, 1921, pp. 753-760, 14 figs.

CHAINS

Anchor. New Method for Manufacture of Anchor Chain, Hubert Hermanns. Forging & Heat Treating, vol. 7, no. 3, Mar. 1921, pp. 156-158, 3 figs. German method of rolling chain from flat strip of wrought iron. Scarf weld is eliminated, making stronger and more uniform anchor chain.

CHARCOAL

Manufacture. The Production of Artificially Dense Charcoal, L. F. Hawley. Jl. Indus. & Eng. Chem., vol. 13, no. 4, April 1921, pp. 301-302, 1 fig. Report for distillation of briquets under mechanical pressure.

CHIMNEYS

Height. A New Method for Proportioning Chimney Heights, Robert Sibley and C. H. Delany. Jl. Electricity & Western Industry, vol. 46, no. 6, Mar. 15, 1921, pp. 299-300, 1 fig. Diagram showing available draft at chimney base for various rates of gas flow and chimney diameters. Rule for determining altitude.

CHROMIUM STEEL

Chromium-Tungsten. Recent Work on Chromium: Tungsten Steel—Method of Magnetic Analysis. Chem. & Metallurgical Eng., vol. 24, no. 13, Mar. 30, 1921, pp. 573-575, 3 figs. Review of literature of chromium-tungsten steels, specially work Japanese investigators. First of series of articles.

Microstructure. Microstructure of Chromium Steels Chem. & Metallurgical Eng., vol. 24, no. 16, April 20, 1921, pp. 703-706, 16 figs. Brief review of literature, especially from Japanese investigator Murakami, presenting structural diagram, photomicrographs and explanation of changes in transformation temperature following various reheatings

CHUCKS

Drill. Application of Interchangeability to Drill Chuck Manufacture. Machy. (Lond.), vol. 17, no. 441, Mar. 10, 1921, pp. 693-699, 9 figs. Tooling and gaging equipment in manufacturing Casler twinscrew drill chuck.

Magnetic. Magnetic Chucks—V, Ellsworth Sheldon. Am. Mach., vol. 54, nos. 14 and 15, April 7 and 14, 1921, pp. 602-605, 9 figs., and 650-652, 7 figs. Chucks manufactured by Blanchard Machine Co.

COAL

Carbonization. The Assay of Coal for Carbonisation Purposes, Thomas Gray and James G. King. Colliery Guardian, vol. 121, no. 3141, Mar. 11, 1921, pp. 716-717, 2 figs. Laboratory method. Technical paper of British Fuel Research Board.

Research. Fuel Research Bureau Advocated to Solve Problems of Scientific Use and Handling of Coal, F. R. Wadleigh. Coal Age, vol. 19, no. 13, Mar. 31, 1921, pp. 581–583. Lancashire and Cheshire (England) coal research association, suggested as model, resembles U. S. war research board, but is broader in scope. Has coal-testing plant and laboratory and also makes commercial investigations. Plan for American commission outlined.

Spontaneous Combustion. Causes of Spontaneous Combustion in Coal and Method of Treatment of Underground Fires, K. Neville Moss. Iron & Coal Trades Rev., vol. 102, no. 2769, Mar. 25, 1921, pp. 425–426, 3 figs. Effect of presence of iron pyrites in connection with underground fires.

COAL DUST

Combating Dangers of. Mine Dusts. Sampling, Testing and Treatment, W. H. McMillan. Iron & Coal Trades Rev., vol. 102, no. 2767, Mar. 11, 1921, pp. 345–346. Methods of combating dangers arising from accumulations of coal dust, with reference to regulations recently enacted by British Government. Paper read before South Midland Branch, Nat. Assn. Colliery Managers.

COAL HANDLING

Belt Conveyor. Belt Conveyor Transfers Coal Across River with Suspension Bridge as Support, R. W. Shumway. Coal Age, vol. 19, no. 12, Mar. 24, 1921, pp. 525–527, 2 figs. With mine on one side of river and railroad on other it was necessary to move coal across stream without interfering with navigation. This was accomplished by means of suspension bridge carrying belt conveyor.

COAL WASHING

Froth Flotation. Froth Flotation as Applied to the Washing of Industrial Coal, Ernest Bury, Walter Broadbridge and Alfred Hutchinson. Trans. Insto. Min. Engrs., vol. 60, part 3, Feb. 1921, pp. 243–253, 4 figs. Principles of froth flotation and account of operation of froth-flotation process. Representative results obtained on various types of material. Economical aspects of process specially as applied to preparation of coal for production of metallurgical coke.

COKE

Testing. Standardizes the Testing of Coke. Iron Trade Rev., vol. 68, no. 15, April 14, 1921, pp. 1037–1038, 2 figs. Committee report of Southern Ohio Pig Iron Assn

COMBUSTION

Surface. The Development of Surface Combustion. (Zur Entwicklung der Oberflächenverbrennung), Otto Essich. Stahl u. Eisen, vol. 41, no. 7, Feb. 17, 1921, pp. 228–232, 16 figs. Gives experiences with small furnaces which, it is claimed, taking into consideration change of conditions, can also be applied to large furnaces.

COMPRESSED AIR

Metering. The Metering of Compressed Air, John L. Hodgson. Trans. Instn. Min. Engrs., vol. 60, part 3, Feb. 1921, pp. 271 280 and (discussion) pp. 280–287, 17 figs. Construction and operation of various types of meters.

CONCRETE

Blast-Furnace Slag. Tests with Blast-Furnace Slag (Versuche mit Hochofenschlacke), H. Burchartz. Stahl u. Eisen, vol. 41, no. 6, Feb. 10, 1921, pp. 193–200, 2 figs. Concrete from blast-furnace slag of the kind tested is said to harden just as well in salt water and is just as durable as gravel concrete. Results of tests show that blast-furnace slag is just as suitable for the production of concrete as natural gravel; and also that the resistivity of cement concrete in salt water is dependent primarily on the density of the concrete material.

Expansion and Contraction. Expansion and Contraction in Concrete Structures, Albert M. Wolf. Eng. World, vol. 18, no. 4, April 1921, pp. 233–236, 1 fig. Experimental results found by various investigators. Derivation of empirical formula for determining net contraction of concrete.

Proportioning. Proportioning Concrete on Job by Exact Methods, R. B. Young and T. V. McCarthy. Eng. News-Rec., vol. 86, no. 11, Mar. 17, 1921, pp. 456–458, 2 figs. Method developed by Hydro-electric Power Commission of Ontatio.

Scientific Concrete (Hormigon científico), Roderick B. Young. Ingenieria Internacional, vol. 5, no. 5, May 1921, pp. 272–275, 4 figs. Method for proportioning aggregates of concrete based on surface of gravel units and experiments conducted to determine best proportions.

The New Methods of Proportioning Concrete in Theory and Practice, Roderick B. Young. Jl. Boston Soc. Civil Engrs., vol. 8, no. 3, Mar. 1921, pp. 73–108, 13 figs. Investigations of hydroelectric power commission of Ontario.

CONCRETE BLOCKS

Casting. The Calculation of Concrete Blocks (Note sur le calcul des pièces en béton de ciment fondu), A. V. Magny. Revue de l'Ingénieur, vol. 28, no.

brick, tile and architectural trim stone.

CONCRETE MIXERS

Sprenger Type. New Process of Making Concrete (Un nouveau procédé de fabrication du béton), E. Weiss. Nature (Paris), no. 2444, Feb. 5, 1921, pp. 95–96, 4 figs. Mixing apparatus invented by M. Sprenger. Wet sand and gravel are blown through atmosphere saturated with cement.

CONCRETE CONSTRUCTION, REINFORCED

Steel Forms. Steel Forms for Concrete Columns and Floor Slabs. Am. Architect, vol. 119, no. 2360, Mar. 16, 1921, pp. 332–334, 6 figs. Description of metal forms used in construction of Columbia Graphophone Co.'s new seven-story structure in Baltimore.

CONCRETE, REINFORCED

Reinforcing Steel. Tests on High Tension Steels in Reinforced Concrete Design, H. Kempton Dyson. Concrete & Constructional Eng., vol. 16, no. 3, Mar. 1921, pp. 161–168, 1 fig. Report of special committee on high tension steel in reinforced concrete of British Concrete Inst.

CONDENSERS, STEAM

Surface. Installations for the Prevention of Scale Formation in Surface Condensers (Anlagen zur Verhütung von Wassersteinbildung in Oberflächen-Kondensationen), Hans Rissmann. Zeit. des Oberschlesischen Berg- u. Hüttenmännischen Vereins, vol. 59, no. 6, 1920, pp. 185–205, 33 figs. Discusses means employed heretofore in prevention of scale formation from the cooling water; describes the Balcke inoculation process as a protection against incrustation and silting up with mud and demonstrates its economic value.

COPPER

Tests. Experiments on Copper Crusher Cylinder, Alexander I. Krynitsky. Dept. of Commerce, Technologic Papers, Bur. of Standards, no. 185, Feb. 1, 1921, 32 pp. 15 figs. Compression tests on standard Riehlé testing machine Length of cylinders decreased considerably under repeated application of load.

COPPER ALLOYS

Copper-Nickel. Copper-Nickel Alloys, Paul D. Merica. Chem. & Metallurgical Eng., vol. 24, no. 13, Mar. 30, 1921, pp. 558–560, 4 figs. Notes on structure and properties of alloys used for driving bands, condenser tubes and coinage. Various names and analyses for nickel silver are tabulated, with notes upon their most common uses.

Copper-Tin. The Constitution of the Alloys of Copper with Tin, III. John L. Haughton. Metal Industry, (Lond.) vol. 18, no. 13, April 1, 1921, pp. 241–247, 7 figs. Transformations other than formation of eutectic, occurring below 250 deg. cent. Range of composition studied was from about 40 per cent tin to 100 per cent tin.

Heat Treatment. Heat Treatment of Copper Alloys, J. S. Glen Primrose. Foundry Trade Jl., vol. 23, no. 241, Mar. 31, 1921, pp. 291–296, 10 figs. Experimental study of effect of heat-treatment upon tensile properties of copper-aluminum and copper-zinc alloys. Paper read before Instn. British Foundrymen.

Properties. Plastic Deformation of Some Copper Alloys at Elevated Temperatures, C. A. Edwards and A. M. Herbert. Engineering, vol. 121, no. 2881, Mar. 18, 1921, pp. 341–344, 11 figs. Also in Metal Industry (Lond.), vol. 18, no. 12, Mar. 25, 1921, pp. 221–229, 11 figs. Apparatus designed by writers for making indentation tests under dynamic stresses. Results of experiments with copper-zinc and copper-aluminum alloys. Paper read before Inst. of Metals.

CORROSION

Boiler Tubes. Unusual Boiler Tube Corrosion by Carbon Dioxide, Barzillai G. Worth. Am. Electrochemical Soc., Thirty-Ninth Gen. Meeting, April 21–23, 1921, no. 28, pp. 329–335, 2 figs. Corrosion was located as due to soluble iron bicarbonate in water used, which gave off large quantities of carbonic acid gas when heated in boiler.

Heating Systems. Practical Means of Preventing Corrosion of Iron and Steel Were Not Exposed Directly to the Atmosphere, F. N. Speller. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 5, pp. 37–46, 2 figs. Method sof deoxidizing water to prevent corrosion in hot-water heating systems.

Iron and Steel. Experiments on the Corrosion of Iron and Steel, T. S. Fuller. Am. Electrochemical Soc., Thirty-Ninth Gen. Meeting, April 21–23, 1921, no. 29, pp. 337–346, 16 figs. Observations of behavior of drops of water standing on pure iron and other metals, also standing partly on iron and partly on zinc or brass. Oxidation is usually perceptible in one minute and quite marked in 15 min.

Some Observations on the Mechanism of the Increased Corrosion Resistance of Steel and Iron Due to Small Copper Contents, D. M. Buck. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 6, pp. 47–53, 3 figs. Results of experiments.

some were in fair condition and others in poor condition.

Iron and Steel Pipe. Control of Corrosion in Iron and Steel Pipes, F. N. Speller. Jl. Eng. Inst. Canada, vol. 4, no. 4, April 1921, pp. 233–237, 2 figs. Causes of corrosion, external and internal, in iron and steel pipe mains with summary of control methods.

Non-Ferrous. Some Types of Non-Ferrous Corrosion, H. S. Rawdon. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 9, pp. 73–79, 8 figs. Examples of each of four types of corrosion: Selective attack of certain constituents; intercrystalline brittleness; internal oxidation; and simultaneous action of stress and corrosion.

Prevention. Principles of Alloying to Resist Corrosion, Oliver P. Watts. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 10, pp. 81–84, 1 fig. General principle is laid down that less corrodible alloys are either metallic compounds of simple chemical formula or solid solutions of more resisting metals in each other. Test proving protective action of copper in steel is given.

Theories. A Practical Aspect of the Corrosion Problem, John F. Thompson. Am. Electrochemical Soc., Thirty-Ninth Gen. Meeting, April 21–23, 1921, no. 30, pp. 347–354. Comparative study of various corrosion theories.

CRANES

Gantry. Special Storage Gantry. Iron Age, vol. 107, no. 16, April 21, 1921, p. 1041, 1 fig. Gantry crane of special design installed at storage yard of Peerless Motor Car Co., Cleveland.

Hammerhead. A Hammerhead Crane for the Harbor of Christiana, Norway (En Stor Kran). Teknisk Ukeblad, vol. 68, no. 2, Jan. 14, 1921, pp. 20–22, 2 figs. Cranes lifts 100 tons to a height of 25 m. and is intended mainly for installation and removal of boilers and ship engines. Its largest radius is 28 m.; motors, operated by alternating current at 220 volts, have a total capacity of 238 hp.

Traveling. Electromagnetic Traveling Crane of Five Tons Capacity and Twenty-Five Meters Radius (Pont-roulant électrique special de 5 tonnes et 25 mètres de portée), W. Druey. Bulletin technique de la Suisse romande, vol. 47, no. 6, Mar. 19, 1921, pp. 66–69, 4 figs. Installed at Oerlikon works for transporting structural steel.

CUTTING TOOLS

Standards. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, (special no.) vol. 3, no. 11, Mar., 1921, pp. 147–152, 7 figs. Proposed new standards for hand wheels, grain-milling rolls, and cutting tools.

CYLINDERS

Block Production. Utilization of Special Machines in Cylinder Block Production, J. Edward Schipper. Automotive Industries, vol. 44, no. 14, April 7, 1921, pp. 756–759, 22 figs. Manufacture of Paige cylinder blocks.

D

DIE CASTING

Developments. Die-Casting Methods and Metals—I, M. H. Potter. Foundry, vol. 49, no. 8, April 15, 1921, pp. 303–306. Advantages and limitations of die casting are discussed and development and present-day practice are outlined.

DIES

Bending. The Design and Construction of Press Tools. Eng. Production, vol. 2, nos. 24 and 26, Mar. 17 and 31, 1921, pp. 346–348, 8 figs., and 404–405, 6 figs. Design of bending and curling dies.

Shells. Dies for Producing a Conical Part, N. T. Thurston. Machy. (N. Y.), vol. 27, no. 8, April 1921, pp. 772–775, 14 figs. Operations in manufacturing system.

DIESEL ENGINES

Marine. Adjustment of Crosshead-Pin Bearings and Main Bearings of Marine Diesel Engines, Louis R. Ford. Power, vol. 53, no. 14, April 5, 1921, pp. 546–547, 3 figs. Details of procedure.

Building Diesel Marine Engines for Seagoing Vessels—II, Fred B. Jacobs. Mar. Rev., vol. 51, no. 5, May 1921, pp. 221–229, 23 figs. Practice at works of Busch-Sulzer Bros., St. Louis, Mo.

The Polar Marine Diesel Engines. Practical Engr., vol. 63, no. 1775, Mar. 3, 1921, pp. 134–137, 4 figs. Four-cylinder type developing 500 b.hp. at 150 r.p.m.

Nordberg. Largest Stationary Diesel Engine in the United States. Power, vol. 53, no. 13, Mar. 29, 1921, pp. 498–501, 7 figs. Nordberg 2000 b.hp. vertical Diesel engine of valve-in-head scavenging two-stroke-cycle, single-acting type. Four power cylinders, 500 b.hp. each, scavenging pump and air compressor driven by crankshaft. Engines to be direct-connected to 1350-kw. a. c. generators to supply electrical service to copper mines.

Oil-Fuel Injection. Some Experiments in Connection with the Injection and Combustion of Fuel Oil in Diesel Engines, C. J. Hawkes. Trans. North-East Coast Instn. Engrs. & Shipbuilders, vol. 37, part 2, Dec. 1920, pp. 37-92, 28 figs. Experiments carried out at British Admiralty Engineering Laboratory in connection with development of high-speed engines for naval purposes.

Standardization. Standardized Diesel Engines—II, H. R. Setz. Mar. Eng., vol. 26, no. 4, April 1921, pp. 324-328, 8 figs. Discussion of construction involving four valves in cylinder head. Study of propelling characteristics.

Werkspoor. The "Werkspoor" Diesel Engines (Inleiding tot het bezichti gen vande Diesel-motoren voor de Billiton-Maatschappij) and (Inleiding tot een bezoek aan de Dieselmotoren-afdeeling van "Werkspoor"), G. J. Lugt. Ingenieur, vol. 36, no. 5, Jan. 1921, pp. 82-87 and 87-94, 25 figs. Describes two large stationary engines, constructed for the Billiton Co., with six cylinders of 5600 by 1000 mm. and 600 r.p.m. which are directly coupled with 3-phase generators; the cylinders are arranged on a distance piece which is tied to base plate; pressure lubrication, combined crankshafts, 3-stage compressors, and cooling of pistons through telescopic tubes. In second paper author discusses certain constructions intended for marine engines only.

DRILL CHUCKS

Manufacture. Application of Interchangeability to Drill Chuck Manufacture—II. Machy. (Lond.), vol. 17, no. 442, Mar. 17, 1921, pp. 725-730, 18 figs. Tooling and gaging equipment employed in manufacturing Casler twin-screw drill chuck.

DRILLING MACHINES

Automatic. Special Automatic Drilling Machines. Iron Age, vol. 107, no. 15, April 14, 1921, p. 975, 1 fig. Machine designed to drill six holes within slotted space 1 in. long on door-lock cylinder. Manufactured by Langelier Mfg. Co., Providence, R. I.

Inverted-Spindle. Defiance Inverted-Spindle Drilling Machine, J. V. Hunter. Am. Mach., vol. 54, no. 15, April 14, 1921, pp. 633-634, 2 figs. Machine constructed by Defiance Machine Works, Defiance, Ohio.

Radial. The Advantage of Rigid Construction in Radial Drilling Machines (Der Vorteil der stabilen Durchbildung von Radial-Bohrmaschinen), Fritz Hensel. Betrieb (special no.), vol. 3, no. 11, Mar. 1921, pp. 302-305, 6 figs. Demonstrates approved construction and economical drive of modern radial drilling machines, and presents curves showing difference in the performance of modern rigid types as compared with older forms of machines.

DRILLS

Standard. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 13, Mar. 25, 1921, pp. 171-180, 11 figs. Proposals of the Board of Directors for tool tapers, Morse tapers, conical reamers for Morse and metric tapers, and metric tapers. As a basis for the standardization of the Morse tapers the original table of the Morse Twist Drill & Machine Co., New Bedford, Mass., is used.

Twist. The Utilization of Broken Twist Drills (Die Wiederverwendung von gebrochenen Spiralbohrern), H. Kummer. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 267-269, 1 fig. Patented device by means of which it is possible to make use of broken twist drills.

Wood Bits and Center Drills. Wood Bits and Adjustable Center Drills (1. Holzbohrer. 2. Verstellbare Zentrumbohrer), Otto Wenzel. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 272-278, 45 figs. Wood bits: Classification of bits according to drilling work; comparison of different kinds with regard to shape and use in auxiliary tools and machines. Adjustable-center drills: Investigation of the different types with regard to cutting angle, adjustability, renewal of separate parts, formation of cutting and strength.

DROP FORGINGS

Malleable Iron versus. Why Drop Forgings Are Replacing Malleable Iron Castings, F. B. Fairbanks. Forging & Heat Treating, vol. 7, no. 3, Mar. 1921, pp. 173-175, 8 figs. Comparative study of photomicrographs.

E

EDUCATION, ENGINEERING

Industrial Production. The Scarcity of the College-Trained Engineer in Production, John Airey. Eng. Education, vol. 11, no. 6, Feb. 1921, pp. 290-297. Suggests college engineering institution spend transitory period as foremen in factory instead of in office or laboratory. This, it is believed, would fit them better to direct production in industry properly.

ELECTRIC DRIVE

Steel Mills. The Frequency Problem in the Steel Industry, B. G. Lamme. Jl. Am. Inst. Elec. Engrs., vol. 40, no. 4, April 1921, pp. 294-300. Possibilities for utilization of 50 cycles. Comparative advantages and disadvantages of 25 and 60 cycles.

ELECTRIC FURNACES

Electrodynamic Forces in. Electrodynamic Forces in Electric Furnaces, Carl Hering. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21-23, 1921, advance paper no. 19, pp. 201-211, 4 figs. Utilization of electrodynamic forces to cause liquid metal to flow rapidly through heat-developing resistor, thereby enabling furnace to be forced and to cause strong upward circulation in adjoining bath, by which metal is refined of suspended impurities and made homogeneous.

Heroult. Electric-Furnace Practice at Treadwell, W. E. Cahill. Min. & Sci. Press, vol. 122, no. 16, April 16, 1921, pp. 535-537, 2 figs. Heroult electric furnace used by Alaska Treadwell Gold Mining Co.

Inductive. Recent Progress in High Frequency Inductive Heating, E. F. Northrup. Am. Electrochemical Soc., Thirty-Ninth Gen. Meeting, April 21-23, 1921, paper no. 18, pp. 179-200, 13 figs. Furnaces of certain types are described and actual performances given, showing them to run at 30 to 40 per cent electrothermal efficiency.

Muffled Arc. Develops New Non-Ferrous Melting Furnace. Iron Trade Rev., vol. 68, no. 16, April 21, 1921, pp. 1115, 2 figs. Muffled-arc type manufactured in two sizes by Gen. Elec. Co.

Muffled Arc Electric Furnace for Non-Ferrous Metals. Iron Age, vol. 107, no. 15, April 14, 1921, pp. 985-986, 4 figs. Type manufactured by Gen. Elec. Co. in two sizes, a 1500-lb. unit and a 50-lb. unit.

New Types of Electric Furnaces. Metal Industry, (N. Y.) vol. 19, no. 4, April 1921, pp. 149-150, 4 figs. Muffled arc furnaces developed by Gen. Elec. Co. for melting non-ferrous metal.

Non-Ferrous Alloys. Electric Furnaces for Non-Ferrous Alloys, H. W. Gillett. Am. Electrochemical Soc., Thirty-Ninth Gen. Meeting, April 21-23, 1921, no. 24, pp. 277-295. Tabulates in detail all electric furnaces in U. S. melting non-ferrous metals giving kind of furnace, users, and capacity per heat. There are 323 electric furnaces in 144 different plants with capacity of 193 tons per single heat and using 42,350 kw.

Non-Ferrous Industry. Electric Melting in Non-Ferrous Industry, Edwin F. Cone. Iron Age, vol. 107, no. 12, Mar. 24, 1921, pp. 770-772. Present status in U. S. Marked increase in last year. Furnaces sold total 408.

New Electric Furnace for Non-Ferrous Industry. Iron Age. vol. 107, no. 12, Mar. 24, 1921, pp. 772-773, 4 figs. Patented H. & H. reverberatory furnace. Heat is changed by means of arcs drawn between vertical electrodes and conducting horizontal bed within furnace.

Open-Hearth Versus. Makes Comparison of Melting Costs. Foundry, vol. 49, no. 8, April 15, 1921, pp. 315-318, 3 figs. Ohio Steel Castings Co. operating both electric and open-hearth furnace gives data covering two processes from which estimated costs are calculated.

Steel Manufacture. Electric Furnaces for Making Steel—II, Alfred Stansfield. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 263-266, 5 figs. Classification of electric steel-making furnaces. General features and advantages of arc furnace and resistance furnace. Operating features of electric furnaces.

Electric Furnaces in Steel Manufacture (Le chauffage dans les fours électriques d'aciérie), M. M. Gillot and M. V. Guillermin. Revue de l'Industrie minréale, no. 5, Mar. 1, 1921, pp. 249-257, 10 figs. Types used.

The Regulation of Electric Steel Arc Furnaces Using Movable Electrodes, W. G. Mylius. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21-23, 1921, advance paper no. 20, pp. 213-225, 8 figs. Discussion of difficulties of operating arc furnaces for melting steel, particularly when melting cold scrap, and of kinds of arc current regulators which have been devised to maintain some function of power imput constant, such as current, voltage, watts, or a combination of these.

ELECTRIC LOCOMOTIVES

Swiss. Swiss Electric Locomotive Progress. Elec. Ry. Jl., vol. 57, no. 16, April 16, 1921, pp. 724-727, 9 figs. Details are given of recent locomotives manufactured by leading two builders of electrical apparatus in Switzerland. Particular attention is given to machines for federal railways. Some experiments with new types of drive are included, indicating leaning toward gears as substitute for side rods.

ELECTRIC WELDING, ARC

Rate of Cutting. Solving Arc Welding Problems, A. M. Candy. Iron Trade Rev., vol. 68, no. 12, Mar. 24, 1921, pp. 829-835, 19 figs. Graphs showing rate of cutting cast iron, malleable iron and steel by arc process. Tests of welds. Paper read before Am. Foundrymen's Assn.

Theory of. Phenomena of Arc Welding, O. H. Eschholz. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21-23, 1921, advance paper no. 8, pp. 59-71, 16 figs. Study of metal deposition, fusion and arc stability during electric welding.

ELEVATORS

Safety Factor for Cables. The Safety Factor in Elevator Cables (Om säkerhetsfaktorn vid hisslinor), Nils Melander. Teknisk Tidskrift (Mekanik), vol. 51, no. 1, Jan. 12, 1921, pp. 14-18. Calculation of the cables. Official regulations for safety factor. Two calculating methods are described, one of which is officially used in Prussia and is recommended by author for use also for self-operating elevators.

EMPLOYEES

Rating. Giving the Worker a Card-Index Rating, Frank H. Williams. Iron Age, vol. 107, no. 16, April 21, 1921, pp. 1033-1035, 1 fig. Practice of S. F. Bowser & Co., Ft. Wayne, Ind., manufacturers of storage systems for oil and gasoline. Employees are marked monthly on 10 points. Records form bases for production.

EMPLOYMENT MANAGEMENT

Employees Lists. What About Your Labor Force When Business Picks Up? Factory, vol 26, no. 7, April 1, 1921, pp. 831-834, 1 fig. Advises record of names, addresses and qualifications of workers applying for positions, even though at time of application they cannot be hired, with a view to insure sufficient supply of workers when production again demands.

Promotion Methods. Keeping Employees in Line for Promotion, Robert I. Clegg. Iron Age, vol. 107, no. 12, Mar. 24, 1921, pp. 761-763, 2 figs. Forms for keeping perpetual inventory of employees giving record of service, successive promotions, personal elements, outside activities, education and hobbies.

ENGINEERS

Civic Duties. Engineering in a Broader Aspect, Dean Mortimer E. Cooley. Michigan Technic, 34, no. 1, Mar. 1921, pp. 18-24. Urges organized cooperation of engineers among themselves and their participation in civic affairs as duties engineers owe to modern complex civilization.

Professional Practice. Operating Costs of Engineering Practice. Eng. News-Rec., vol. 86, no. 13, Mar. 31, 1921, pp. 542-543, 3 figs. Factors include education, capacity, class of work, and direct and indirect expenses of business. Organization chart of an engineering firm. Forms for cost keeping.

Registration. Licensing of Engineers. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 3, April 1921, pp. 326-335. Abstract covering present status of legislation for licensing of engineers in various states. Report of Publication Committee, Am. Soc. of Heat & Vent. Engrs.

Remuneration. Fees for Practicing Engineers. Eng. World, vol. 18, no. 4, April 1921, pp. 247-251, 4 figs. Progress report made by committee of Am. Assn. of Engrs.

EXCAVATORS

Mechanical. Mechanical Excavators (Les excavateurs mécaniques). Génie Civil, vol. 78, no. 9, Feb. 26, 1921, pp. 185-190, 12 figs. Survey of recent developments and uses.

EXPLOSIONS

Grain Dust. Dust Explosion at Large Chicago Grain Elevator. Eng. News-Rec., vol. 86, no. 13, Mar. 31, 1921, pp. 560-562, 2 figs. Explosion in Chicago grain elevator of Chicago & Northwestern Railway. Six men were killed and 4 injured, and about 500,000 bushels of grain were lost or damaged.

F

FACTORIES

Construction. Auto Body Plant Built of Reinforced Concrete, V. E. Winell. Concrete, vol. 18, no. 4, April 1921, pp. 160-164, 6 figs. Plan and layout of Fisher Body Ohio Co.'s plant.

Layout. Plant Layout Studies by Concrete Institute Committee. Eng. News-Rec., vol. 86, no. 12, Mar. 24, 1921, pp. 505-507, 4 figs. Report submitted at annual convention embodies description of, and comparative costs upon seven fundamental types.

FACTORY MANAGEMENT

See INDUSTRIAL MANAGEMENT.

FATIGUE

Steel Works. Fatigue and Efficiency in Iron and Steel Works—IV, H. M. Vernon. Eng. & Indus. Management, vol. 5, no. 11, Mar. 17, 1921, pp. 320-323, 2 figs. Investigations undertaken for British Industrial Fatigue Research Board. Influence of reduction of hours on rolling-mill output.

FERRONICKEL

Anomaly of Expansion. Effect of Additions in the Anomaly of Expansion of Ferronickels—Application to Ferro-Nickel-Chrome Alloys (L'action des additions sur l'anomalie de dilatation des ferronickels; application aux alliages fer-nickel-chrome), M. P. Chevenard. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 10, Mar. 7, 1921, pp. 594-596, 2 figs. Graphs plotted from results obtained in experiments.

FILES

Handles. Steel Files with Attachable Handles. (Bezugfeilen), Karl Küssner. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 263-265, 7 figs. Sets forth advantages of described type and points out that for special purposes special files of this system are made with which the inside walls of steam-engine cylinders can be treated.

Revolving. Rotating Files (Rotierende Feilen), F. Karpinski. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 259-263, 9 figs. Describes new method using a rapidly revolving round file which, it is claimed, in many cases and particularly for special purposes, effects considerable saving in labor and greater accuracy of work.

FIREBRICK

Tests. Comparing Brick for Boiler Furnace Linings, R. C. Brierly. Combustion, vol. 4, no. 4, April 1921, pp. 20-22 and 41, 2 figs. Records of tests.

FLOW OF LIQUIDS

Short Tubes. The Flow of Liquids Through Short Tubes, Winslow H. Herschel. Proc. Am. Soc. Civil Engrs., vol. 47, no. 3, Mar. 1921, pp. 35-36. Tests on "inverted" Saybolt Universal viscosimeter. Determination of kinetic energy correction for turbulent flow from experiments of Couette. (Abstract.)

FLOW OF WATER

Measurements. Measuring Water Flow for Power Purposes, N. R. Gibson. Mech. Eng., vol. 43, no. 4, April 1921, pp. 247–248, 1 fig. Description of Gibson method and apparatus and account of its application in efficiency tests of 37,500-hp. turbines of Niagara Fall Power Co. Mean velocity of column of water in penstock by recording changes of pressure at point in pipe line when flow of water therein is gradually brought to rest by closing valve or turbine gates. Mean change or pressure recorded is measure of velocity destroyed.

FOUNDRIES

Mechanical Equipment. Pulleys Predominate in Unique Shop, Pat Dwyer. Foundry, vol. 49, no. 8, April 15, 1921, pp. 293–299, 12 figs. Practice in handling materials at foundry of Hill Clutch Co., Cleveland.

Stove. Specialty Shop Shows Versatility. Foundry, vol. 49, no. 7, April 1, 1921, pp. 265–270, 10 figs. Method and process of foundry at Fanner Mfg. Co., Cleveland, manufacturers of stoves and other articles.

FREIGHT HANDLING

Bibliography. Bibliography on Freight Handling, R. F. Emerson. Gen. Elec. Rev., vol. 24, no. 4, April 1921, pp. 371–380. List of articles on general subject of material handling that have appeared in technical press since 1914.

FUELS

Ash, Fusibility of. What Constituents in Ash Cause It to Fuse, G. A. deGraaf. Coal Age, vol. 19, no. 12, Mar. 24, 1921, pp. 534–539, 5 figs. Graphs showing relation of fusing temperature of ash to percentage of silica, iron oxide and sulphur.

Calorific Value. A Proposed New Measure of Calorific Power, E. Damour. Gas Jl., vol. 154, no. 3021, April 6, 1921, pp. 29–30, 1 fig. Measurement of calorific power of fuels, particularly wood, peat and lignite and other substitutes for coal. Duplex-combustion producer furnace for utilization of low-grade fuels. Translated from Chimie et Industrie.

Carbocoal. The Smith Continuous System of Carbonization, George H. Thurston. Jl. Soc. Chem. Industry, vol. 40, no. 5, Mar. 15, 1921, pp. 51T–56T, 4 figs. Combination of low and high temperature carbonization. Coal is crushed to pass 3/8-in. mesh screen and is subjected to primary carbonization at temperature of about 480 deg. cent. to reduce its volatile content to uniformly low figure, whereby it is converted into friable residue containing 7 to 10 per cent of volatile matter, called semi-carbocoal. After passing through retort material is ground and mixed with suitable percentage of pitch and briquetted.

Carbozite. Carbozite (Karbozit), H. R. Trenkler. Feuerungstechnik, vol. 9, no. 11, Mar. 1, 1921, pp. 93–95, 2 figs. Said to be a refined product of lignite, wood or peat, which is not a coked material but a kind of artificial rough coal, differing in this respect from carbocoal which is a semi-coke from anthracite. The chemical and thermotechnical basic principles of process are discussed.

Colloidal. Properties and Characteristics of Colloidal Fuel, Lindon W. Bates and Haylett O'Neill. Power Plant Eng., vol. 25, no. 7, April 1, 1921, pp. 368–369, 2 figs. Graphs showing heating value of colloidal fuel of different compositions. Papers read before Royal Soc. Arts.

Domestic. The Relative Efficiency of Coal, Gas, and Electricity for Domestic Purposes, E. Marsden and (Miss) E. W. J. Fenton. New Zealand Jl. Sci. & Technology, vol. 3, nos. 5 & 6, Jan. 1921, pp. 257–270, 7 figs. It was found in tests that gas is over three times and electricity over four times more expensive for general domestic purposes than coal.

Economical Utilization. Work of the Committee on Utilization of Fuels (Travaux de la commission d'utilisation des combustibles), V. Kammerer. Bulletin de la Société d'Encouragement pour l'Industrie nationale, vol. 120, no. 3, Mar. 1921, pp. 286–301. Committee report submitted to French Ministry of Public Works. Instructions are formulated for engineers and assistants and suggestions are given in regard to economical production and utilization of steam. From Journal officiél, Feb. 20, 1921.

Recovery from Furnace Residues. Recovery of Fuel from Furnace Residues (Brennstoffgewinnung aus den Feuerungsrückständen), H. Winckel. Gesundheits-Ingenieur, vol. 44, no. 3, Jan. 15, 1921, pp. 31–32. Describes process and the Kolumbus ash separator of firm of Benno Schilde, Hersfeld, according to which the fine ashes and the large pieces of slag are sifted from the residue after which the heavy slags are separated from the light coke in a liquid of 25 to 30 deg. Baumé by means of the specific weight.

The Kolumbus Separator and the Schilde Process for the Treatment of Furnace Residues (Der Kolumbus-Separator und das Schildeverfahren zur Aufbereitung der Fererungsrückstände), H. Pradel. Elektrotechnischer Anzeiger, vol. 38, no. 30, Feb. 23, 1921, pp. 155–156, 2 figs. Describes new wet process introduced by firm of Benno Schilde, Hersfeld, Germany, in which separating liquid is used which is heavier than water, and the Kolumbus separator used in connection therewith, said to be a comparatively simple and cheap apparatus produced in three sizes. Its economical advantages are set forth.

[See also ASHES LIGNITE; OIL FUEL; PEAT; PULVERIZED COAL.]

FURNACES, ANNEALING

Sheet. Heating Furnaces and Annealing Furnaces, W. Trinks. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 267–272, 20 figs. Comparison of different types of sheet furnaces.

FURNACES, BOILER

Construction. Working Pressures on Furnaces, John S. Watts. Boiler Maker, vol. 21, no. 4, April 1921, pp. 112–114, 1 fig. Chart for calculating thickness of boiler furnaces to conform with requirements of principal classification societies.

Types. The Behavior of Fuels in Boiler Furnaces and Measures for Heating Them (Das Verhalten der Brennstoffe in den Kesselfeuerungen und die Massnahmen für ihre Verheizung), H. Deinlein. Zeit. des Bayerischen Revisions-Vereins, vol. 25, nos. 3 and 4, Feb. 15 and 28, 1921, pp. 17–19 and 28–30. Notes on influence of the heating value of coal on utilization of heat, draft requirement of a fuel, water content, rate of combustion, and air requirement. Discussion of horizontal-grate, step-grate and traveling-grate furnaces.

FURNACES, FORGING

Gas-Fired. The Application of Gas to Forging Furnaces. Forging & Heat Treating, vol. 7, no. 3, Mar. 1921, pp. 178–181. Results of tests. Paper read before Am. Gas Assn.

FURNACES, HEATING

Ingot. Heating Furnaces and Annealing Furnaces, W. Trinks. Forging & Heat Treating, vol. 7, no. 3, Mar. 1921, pp. 159–161, 8 figs. Critical comparison of different types of furnaces in use for heating of heavy forging ingots.

FURNACES, HEAT-TREATING

Oil Burning. Heat Treating Plant at Nash Motor Works. Iron Age, vol. 107, no. 14, April 7, 1921, pp. 895–898, 5 figs. Double carbonizing furnaces heated by oil. Automatic signal system on columns indicates furnace temperatures. Corrugated steel wall shuts heat from room.

G

GAGES

Dial. Capstan Dial Gauge. Engineering, vol. 121, no. 2881, Mar. 18, 1921, pp. 322–323, 5 figs. Indicator gages constructed by Coventry Gauge & Tool Co., England.

Precision. Precision Gauge Manufacture, Arthur G. Robson. Engr., vol. 131, no. 3404, Mar. 25, 1921, pp. 312–314, 26 figs. Jigs and fixtures employed. Example of calculations involved.

Spline. Making Inserted Spline Gauges. Machy. (Lond.), vol. 18, no. 443, Mar. 24, 1921, pp. 768–770, 6 figs. Method of milling splines and flats.

GAS ENGINES

Waste-Heat Utilization. The Utilization of Waste Heat from Gas Engines (Abwärmeverwertung bei Gasmaschinen), W. Schlachter. Oel- u. Gasmaschine, vol. 18, nos. 1 and 2, Jan. and Feb. 1921, pp. 9–12 and 22–23. Method of utilizing waste heat of cooling water.

GAS TURBINES

Developments. Gas Turbines (Ueber Gasturbinen), H. Sickel. Elektrotechnischer Anzeiger, vol. 38, nos. 32 and 33, Feb. 26 and Mar. 1, 1921, pp. 165–166 and 177–178, 3 figs. Notes on present and future development.

GEAR CUTTING

Fixtures. Efficient Fixtures Used in Gear Cutting, Douglas T. Hamilton. Can. Machy. vol. 25, no. 13, Mar. 31, 1921, pp. 33–36, 10 figs. Methods of testing truth of arbor and work.

GEAR DRIVE

Friction Losses. Running Loss and Temperature Increase in Gear Drives (Arbeitsverlust und Temperaturerhöhung bei Triebwerken), H. Bonin. Betrieb, vol. 3, no. 13, Mar. 25, 1921, pp. 377–378. It is shown that the increase in temperature of gear drive due to friction is an indication of the running losses caused by the friction, for the numerical evaluation of which, however, extended experimental data are necessary.

GEARS

Bevel. Turning Bevel Gear Blanks. Eng. Production, vol. 2, no. 26, Mar. 31, 1921, pp. 411–414, 13 figs. Production on automatic machines.

Helical. The Production of Helical Gears. Eng. Production, vol. 2, no. 27, April 7, 1921, pp. 440–443, 8 figs. Procedure in works of Citroën Gear Co., France.

Involute. Angles of Approach, Recess and Contact of Involute Gears, A. B. Cox. Am. Mach., vol. 54, no. 13, Mar. 31, 1921, pp. 559–561, 6 figs. Derivation of formulas.

Involute Gear Problems, H. E. Kitchen. Machy. (London.), vol. 18, no. 445, April 7, 1921, pp. 11–14, 6 figs. Enlarging gears without backlash. Avoidance of undercut.

The Evolution of the Involute Gear Tooth, A. Fisher. Machy. (Lond.), vol. 17, nos. 441 and 444, Mar. 10 and 31, 1921, pp. 714–718, 9 figs., and 806–809, 11 figs. Early solutions of odontoid; general rolled curve or roulette solution.

Maag System. The Maag System of Gearing—I. Engr., vol. 131, no. 3403, Mar. 18, 1921, pp. 283–285, 5 figs. Generating cutting machine. Involute teeth are generated by means of reciprocating rack cutter with straight-side teeth.

Production System. Quantity Production in a Gear Shop—I, Fred R. Daniels. Machy. (N. Y.), vol. 27, no. 8, April 1921, pp. 763–766, 10 figs. Practice of Dittmer Gear & Mfg. Corp., Lockport, N. Y., in manufacture of gears for tractors, trucks and automobiles.

Worm. Calculating Chart for Worm Gear as a Basis for Standardization (Berechnungstafel für Schneckengetriebe als Grundlage für die Normung derselben), Friedrich Woltzendorff. Betrieb, vol. 3, no. 9, Feb. 10, 1921, pp. 234–238, 2 figs. Recommendations for standardization of worm gear supplementary to those published in same journal (vol. 14, no. 2, 1920). An improved chart is presented and calculation thereof explained.

GOLD METALLURGY

Antimonial Ore Treatment. Treatment of Antimonial Gold Ore at the Globe and Phoenix Gold Mine, Southern Rhodesia, V. E. Robinson. Jl. Chem., Metallurgical & Min. Soc., vol. 21, no. 7, Jan. 1921, pp. 117–119. Owing to stibnite present and also possibly to ferrous iron, tailing cannot be treated directly by cyanide, but if it be allowed to partially oxidize by weathering, it becomes amenable to cyaniding.

GRINDING

Cylindrical. Points to Consider in Cylindrical Grinding, W. H. Chapman. Can. Machy., vol. 25, no. 13, Mar. 31, 1921, pp. 41–44, 2 figs. Factors which determine wheel-wearing action. Laws relating to draw-in and traversed cuts. Production costs.

Fixtures. The Use of Special Fixtures in Grinding Operations, Ellsworth Sheldon. Am. Mach., vol. 54, no. 13, Mar. 31, 1921, pp. 545–548, 14 figs. Use of gear as chuck upon which to finish another gear. Grinding tapers without traverse.

GRINDING MACHINES

British-Built. The Coventry Centreless Grinder, H. A. Dudgeon. Machy. (Lond.), vol. 17, no. 444, Mar. 31, 1921, pp. 789–792, 14 figs. Machines manufactured by B.S.A. Tools, Birmingham.

German. Modern Grinding Machines (Neuere Schleifmaschinen), W. Pockrandt. Zeit des Vereines deutscher Ingenieure, vol. 65, no. 12, Mar. 19, 1921, pp. 289–291, 37 figs. on 2 supp. plates. Cylindrical surface and piston-ring grinding machines built by Reinecker (Chemnitz).

H

HACK-SAWING MACHINES

Automatic. Automatic Hack Sawing Machine. Machy. (Lond.), vol. 18, no. 443, Mar. 24, 1921, pp. 784–785, 4 figs. Manufactured by Edward G. Herbert, Manchester, England.

HANDLING MATERIALS

Electrically Operated Machinery. The Field for Electrically Operated Material Handling Machinery, F. T. Smith. Gen. Elec. Rev., vol. 24, no. 4, April 1921, pp. 361–365, 6 figs. Typical installations.

Freight-Handling Devices. A Brief Directory of Material Handling Apparatus, R. H. McLain. Gen. Elec. Rev., vol. 24, no. 4, April 1921, pp. 306–317, 46 figs. Descriptions and illustrations of freight-handling devices which are suitable for handling different classes of material through horizontal and vertical motion over long and short distances.

Routing. The Application of Power-Driven Machinery to the Horizontal Transference of Miscellaneous Freight, J. A. Jackson. Gen. Elec. Rev., vol. 24, no. 4, April 1921, pp. 325–330, 6 figs. Fundamental principles of routing that must be observed to secure efficient system for transferring miscellaneous freight or material within building.

HARDNESS

Testing. The Study of Bar Hardness Tests (Étude sur l'essai de dureté a la bille), René Guillery. Mémoires et Compte rendu des Travaux de la Société des Ingenieurs Civils de France, vol. 73, nos. 10, 11 and 12, Oct.-Dec. 1920, pp. 591–606, 22 figs. partly on supp. plate. Research on the elimination of time elements in Brinell tests. Apparatus measuring by impact given by hammer.

HEATING AND VENTILATION

Fire Hazards. Fire Hazards Connected with Heating and Ventilating Work, Ira H. Woolson. Jl. Am. Soc. Heat. & Vent. Engrs., vol. 27, no. 3, April 1921, pp. 286–292. Suggestions based upon statistics of insurance losses paid by companies reporting to Actuarial Bur. of Nat. Board of Fire Underwriters for five years 1915–1919 inclusive.

HEATING, ELECTRIC

Heating and Cooking Apparatus. The Status of Electric Heating and Cooking Apparatus (Der Stand der elektrischen Heiz- und Kochapparate), H. Wintermeyer. Elektrotechnischer Anzeiger, vol. 38, no. 44, Mar. 19, 1921, pp. 253–258, 4 figs. Review of foreign and domestic patented improvements.

Switzerland. The Employment of Electricity for Heating (Die Verwendung der Elektrizität in der Heizungstechnik), R. Gautschi. Gesundheits-Ingenieur, vol. 44, no. 2, Jan. 8, 1921, pp. 13–17, 6 figs. Describes construction and operation of electric central and separate heating installations in Switzerland. Comparison of the cost of heating with use of black and white coal. Notes on hot-water heating operated with night current; heat storage tanks, electrically heated high-pressure boilers, etc.

HEAT TRANSMISSION

Building Materials. The Heat Conduction Coefficients of Building and Insulating Materials and the Coefficient of Permeability of New Building Types (Die Wärmeleitzahl von Bau und Isolierstoffen und die Wärmedurchlässigkeitzahl neuer Bauweisen), Osc. Knoblauch, E. Raisch and H. Reiher. Gesundheits-Ingenieur, vol. 43, no. 52, Dec. 25, 1920, pp. 607–623, 4 figs. Part I gives results of experiments carried out in years 1912–1920 for determination of heat conductivity of building and insulating materials. Part II gives results of tests carried out consecutively since 1918 on experimental houses for determination of permeability of certain wall constructions. The most important conclusions are summarized. See also same journal, vol. 44, no. 9, Feb. 26, 1921, pp. 100–101. (Remarks by H. Chr. Nussbaum.)

Radiation. Present Status of the Constants and Verification of the Laws of Thermal Radiation of a Uniformly Heated Inclosure, W. W. Coblentz. U. S. Dept. of Commerce, Sci. Papers, Bur. of Standards, no. 406, Dec. 20, 1920, 48 pp. Examination into various determinations and methods employed in determining radiation constants by different experimenters. Comparison of accuracy of results obtained therewith.

HELICOPTERS

Berliner. The New Berliner Helicopter. Aviation, vol. 10, no. 13, Mar. 28, 1921, pp. 393, 2 figs. Helicopter invented by H. A. Berliner of Washington, D. C.

Modern Types. Independent Sustentation of an Aeroplane in Air (Vers la sécurité: la sustentation indépendante), M. Lamé. Aérophile, vol. 29, nos. 3 & 4, Feb. 1–15, 1921, pp. 46–49, 6 figs. Details of modern helicopters—Crocker-Hewitt, Alérion, Pescara Oehmichen.

Oehmichen. Flight Tests Performed with Oehmichen Helicopter in January 1921 (Vols d'essai realisés avec un hélicptère libre monté, système Oehmichen (janvier 1921). Génie Civil, vol. 78, no. 11, Mar. 12, 1921, pp. 237–238, 1 fig. Apparatus is provided with two 2-bladed propellers of 6.40 meters diameter rotating in opposite directions in same horizontal plane.

Study of. The Helicopter—I, M. A. S. Riach. Aeronautics, vol. 20, no. 389, Mar. 31, 1921, pp. 223–224, 1 fig. Technical study. (To be continued.)

HOISTS

Skip. Provisions that Enable the Skip Hoist at Coal Mines to Give Maximum Service, Andrews Allen and John A. Garcia. Coal Age, vol. 19, no. 12, Mar. 24, 1921, pp. 529–533, 4 figs. Where skip hoisting is employed bottom layout differs radically from that used with cage hoisting. Although four kinds of dumps are available rotary is variety most generally installed. Paper read before Am. Inst. Min. & Metallurgical Engrs.

HOUSE ORGANS

Editorial Policies. Industrial Publicity and the House Organ, Charles E. Carpenter. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 247–249. Developments of industrial publicity. Note on editorial policies to follow in house organs.

HOUSES, CONCRETE

Construction. Recommended Practice for Concrete House Construction. Eng. & Contracting, vol. 55, no. 12, Mar. 23, 1921, pp. 278–279. Report of committee on concrete houses, Am. Concrete Inst.

Fireproofing. Fireproofing a Concrete Block House, Wharton Clay. Eng. World, vol. 18, no. 4, April 1921, pp. 275–276. Recommendation of Nat. Conference of concrete house construction.

Ingersoll-Rand System. How the Ingersoll-Rand Company is Solving Its Housing Problem with Concrete. Concrete Age, vol. 33, no. 6, Mar. 1921, pp. 18–23, 6 figs. Wooden forms are set up for making complete house in one operation.

Machine-Made. Machine-Made Reinforced Concrete Houses and Other Structures, F. G. Engholm. Can. Engr., vol. 40, no. 13, Mar. 31, 1921, pp. 337–342, 6 figs. Details of machine-made parts for concrete structures.

HYDRAULIC TURBINES

Design. The Modern Hydraulic Turbine, Frank H. Rogers. Jl. Engrs. Club of Phila., vol. 38–3, no. 195, Mar. 1921, pp. 77–90, 25 figs. Modern requirements. Tests on models as adjunct to design. General and special features of design.

Development. The Present Trend of Turbine Development, Lewis F. Moody. Mech. Eng., vol. 43, no. 4, April 1921, pp. 235–244, 17 figs. Also Jl. Engrs. Club of Phila., vol. 38–3, no. 195, Mar. 1921, pp. 106–123, 25 figs. Brief survey of past history and recent progress, together with discussion of theoretical problems involved in hydraulics of modern high-speed turbine, notably determinations of turbine and pump efficiencies as related to specific speed.

Efficiency. Economic Importance of the Efficiency of Hydraulic Turbines for New Construction and Reconstruction (Wirtschaftliche Bedeutung des Wirkungsgrades der Wasserturbinen für Entscheidungen beim Neubau und Umbau), H. Leiner. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 9, Feb. 26, 1921, pp. 222–224. Development of equations to be considered in the determination of economic efficiency of turbines. It is shown that old installations have for the most part lost their significance from an economic standpoint. In the case of new construction, selection of construction type should be made with due regard to economic influence of its efficiency.

Maximum Efficiency of Turbines (Sur le rendement maximum des turbines), M. de Sparre. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 10, Mar. 7, 1921, pp. 561–564. Formulas.

Thermometric Method for Measuring Efficiency of Hydraulic Turbines (Sur une méthode thermométrique de mesure du rendement des turbines hydrauliques), L. Barbillion and A. Poirson. Houille Blanche, vol. 19, nos. 47 and 48, Nov.–Dec. 1920, pp. 217–221, 2 figs. Principle of method consists in assuming that quantity of heat corresponding to energy loss is employed in heating water.

Efficiency Tests. The Application of a New Method of Water Measurement in the Efficiency Tests of the 37,500 H.P. Turbines of the Niagara Falls Power Company, N. R. Gibson. Jl. Engrs. Club of Phila., vol. 38–3, no. 195, Mar. 1921, pp. 90–101, 18 figs. Description of Gibson method and apparatus for measuring flow of water in penstocks. Comparison of volumetric and Gibson measurements.

Speed Regulation. Speed Regulation of the Hydraulic Turbine, Raymond D. Johnson. Mech. Eng., vol. 43, no. 4, April 1921, pp. 245–246 and 248, 2 figs. Also Jl. Engrs. Club of Phila., vol. 38–3, no. 195, Mar. 1921, pp. 101–106, 7 figs. Notes on design of surge tanks. Graph showing typical variations of water level in both tank and standpipe of differential regulator.

HYDROELECTRIC PLANTS

California. An Emergency Hydroelectric Plant, Geo. H. Bragg. Jl. Electricity & Western Industry, vol. 46, no. 7, April 1, 1921, pp. 340–342. Construction work on Pacific Gas & Elec. Co. of California during 1920 power shortage.

Canada. Canada's Superpower Zone, Robert G. Skerrett. Sci. Am., vol. 124, no. 13, Mar. 26, 1921, pp. 246 and 258, 1 fig. Scheme worked out by Ontario hydroelectric power commission.

Hydro-Electric Progress in Canada During Past Year, J. B. Challies. Contract. Rec., vol. 35, no. 12, Mar. 23, 1921, pp. 298–301. In 1920, 650,000 hp. was completed or under construction. Active government development of power resources. Canada next to Norway in amount developed.

France. Utilization of the Hydraulic Energy in the Vienne River in West of France (Usines électriques de la Société des Forces motrices de la Vienne), Auguste Pawlowski. Génie Civil, vol. 78, no. 14, April 2, 1921, pp. 285–289, 10 figs. Construction of three plants, one of 6000 hp., one of 8000 hp. and one of 9000 hp.

Electrical Features. Electrical Features of Hydro-Electric Power, David Barker Rushmore. Jl. Engrs. Club of Phila., vol. 38–3, no. 195, Mar. 1921, pp. 123–129. Enumeration of electrical apparatus involved.

Queenston-Chippewa Project, Ontario. 50,000-Hp. Wheels for 500,000-Hp. Plant, E. T. J. Brandon. Elec. World, vol. 77, no. 13, Mar. 26, 1921, pp. 697–699, 6 figs. Five 45,000-kva. generators already on order for Queenston-Chippewa project in Ontario. Unit system followed for electrical layout. Generators set below floor level. Control pedestals at generators.

Sweden. The Glomfjord Hydroelectric Plant, Sweden (Glomfjord Kraftanlæg), Ragnvald Lie. Teknisk Ukeblad, vol. 68, nos. 5 and 6, Feb. 4 and 11, 1921, pp. 50–53 and 61–65, 10 figs. The available volume of water is 25 cu.m. per sec. and is supplied from a number of lakes located in high altitudes; the entire water supply is 585 million cu.m., the head, 450 m. At present six turbines for 160,000 hp. are to be installed, of which 25,000 hp. are to be held as reserve. Notes on preliminary construction work.

Switzerland. New Hydroelectric Plant under Construction in the Canton of Grisons, Switzerland (Die Landquartwerke der "Bündner Kraftwerke"), R. Moor. Schweizerische Bauzeitung, vol. 77, no. 12, Mar. 19, 1921, pp. 127–130, 7 figs. Details of Kloster-Kublis power plant designed by and being constructed under supervision of writers. Plant is first stadium of large project for harnessing Landquart river and its tributaries.

I

ICE PLANTS

Electric vs. Steam Drive. Electrification of the Ice Industry, Donald Cole. Ice & Refrigeration, vol. 60, no. 3, Mar. 1921, pp. 175–176. Comparison of manufacturing costs in electrically driven and steam-driven ice plants.

IGNITION

Coil Sparks. Phenomena of the Ignition of Gaseous Mixtures by Induction Coil Sparks, John David Morgan and Richard Vernon Wheeler. Jl. Chem. Soc., vols. 119 & 120, no. 701, Mar. 1921, pp. 239–250, 10 figs. Experiments on different mixtures of methane and air.

INDICATORS

Steam-Engine. Determination of the Continuous Output of Reciprocating Steam Engines (Die Feststellung der Dauer-Betriebsleistung von Kolbendampfmaschinen). Kali, vol. 15, no. 4, Feb. 15, 1921, pp. 53–58, 6 figs. Power meter and load indicator with recording device constructed by Anton Böttcher, Hamburg, and power meter by Gümbel, Charlottenburg.

INDUSTRIAL MANAGEMENT

Attitude of Organized Labor. Union Labor and the Enlightened Employer, Samuel Gompers. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 235–239. Attitude of organized labor toward management, open shop crusade, collective bargaining, and present day economic problems.

Accident Prevention. Safety and Accident Prevention, Fred G. Lange. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 257–259. Explains accident prevention as phase of industrial management.

Central Control. Central Control System in the Franklin Plant, Franklin D. Jones. Machy. (N. Y.), vol. 27, no. 8, April 1921, pp. 745–749, 6 figs. Also in Machy. (Lond.), vol. 18, no. 445, Apr. 7, 1921, pp. 1–5, 6 figs. System employed by H. H. Franklin Mfg. Co., for regulating output according to demand, and for controlling manufacturing operations by mechanical boards or charts and pneumatically operated dispatch system.

Developments. The Evolution of Industrial Management, Henry R. Towne. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 231–233. Review of developments during last 30 years.

Thirty Years of Management Literature, John R. Dunlap. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 279–283 and 311. Survey of developments in industrial management. (To be continued.)

Gantt's Method of Inquiry. Principles of Industrial Philosophy, Walter N. Polakov. Mech. Eng., vol. 43, no. 4, April 1921, pp. 249–252 and (discussion) pp. 253–254, 5 figs. Gantt's method of inquiry into co-relation of social needs and industrial services. Application and influence of principles enunciated by Gantt.

Incentives to Workers. Incentives to Better Workmanship Appeal to a Variety of Instincts, Norman G. Shidle. Automotive Industries, vol. 44, no. 13, Mar. 31, 1921, pp. 712–714. Plan of classification of employees and opportunities offered for their advancement at plant of Sperry Gyroscope Co.

Instruction Sheets. Proposals for New Factory Instruction Sheets (Entwürfe neuer Betriebsblätter). Betrieb, vol. 3, no. 12, Mar. 10, 1921, pp. 84–85. Proposals of Committee for Economic Production for instruction sheet for the handling and erection of machine tools.

Production Systems. Making Pay Envelopes Reflect Merit, R. A. Ilg. Factory, vol. 26, no. 7, April 1, 1921, pp. 837–839, 3 figs. Production records are posted where employees can see them. Bulletin board causes workman's natural pride to show itself in increased production. Bonuses are paid for increased production.

Production in a General Engineering Shop. Eng. Production, vol. 2, no. 25, Mar. 24, 1921, pp. 385–390, 16 figs. Works and methods of Messrs. Peter Brotherhood, Ltd., London.

The Trend Toward Automatic Production, A. L. DeLeeuw. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 251–255. Developments in production systems during last 30 years.

Works Organization. Eng. Production, vol. 2, no. 25, Mar. 24, 1921, pp. 391–395, 15 figs. Production systems of British automobile manufacturer.

Routing Materials. Co-Ordinating the Industrial Plant Through Intra-Factory Transportation, W. F. Merrill. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 261–265, 5 figs. Economics of intra-factory transportation.

Toolroom Organization. Distribution of Tools (Die Werkzeugausgabe), Th. Damm. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 282–284, 3 figs. Fundamental aspects are discussed, and practical equipment, arrangements and organization methods are suggested which have proved successful in practice.

INDUSTRIAL RELATIONS

American Industries. What America Faces, Herbert Hoover. Indus. Management, vol. 61, no. 7, April 1, 1921, pp. 225–229. Review and forecast of fundamental relationships between employer and employee. It is pointed out that although there are no conflicts of interest between employee and employer, there are also "wide areas of activity in which their interests should coincide, and it is the part of statesmanship on both sides to organize this identity of interest in order to limit the area of conflict."

Electrical Construction Industry. National Labor Council for the Electrical Construction Industry. Monthly Labor Rev., vol. 12, no. 3, Mar. 1921, pp. 126–127. Plan adopted in April 1920, by Nat. Assn. of Elec. Contractors and Dealers and Nat. Brotherhood of Elec. Workers. Purposes of Council are said to be "promotion of peace and harmony in electrical industry, the adjudication of disputes between employers and employees, the establishment of friendly relations between all parties interested, which should ultimately result in the elimination of distrust, suspicion, and the wasteful methods of the old-fashioned strikes and lockouts."

Pennsylvania Railroad. Joint Reviewing Committee of the Pennsylvania Railroad System. Monthly Labor Rev., vol. 12, no. 3, Mar. 1921, pp. 122–125. Duty of Reviewing Committee is "amicable settlement, by joint conference, of all controversial questions affecting engine and train service men." Plan was adopted at meeting held on Dec. 29, 1920 by representatives of employees and representatives of administrative force of railroad.

Plans. Industrial Relations Work Pays, James W. Brown. Iron Trade Rev., vol. 68, no. 13, Mar. 31, 1921, pp. 906–908. Outlines plan to promote family spirit in industrial life of all employees. Paper read before Am. Foundrymen's Assn.

Shop Councils. One Year of the Shop Council System in Germany. Am. Mach., vol. 54, no. 16, April 21, 1921, pp. 682. Occasional strikes, steady rise in wages, unwarrantable interference and failure in increasing production are conditions reported by managers of industrial works.

INDUSTRIAL TRUCKS

Electric. Electric Vehicles for Railway Cartage Work. Ry. Gaz., vol. 34, no. 11, Mar. 18, 1921, pp. 426–427 and 429, 5 figs. Trucks used by Great Northen Ry., England. Data on running costs.

Electric Trucks and Industrial Locomotives. Engr., vol. 131, nos. 3403 and 3404, Mar. 18, and 25, 1921, pp. 290–292 and 294, 10 figs., and 318–319, 6 figs. Typical British designs.

INTERNAL-COMBUSTION ENGINES

Compensation Gear. Tappet Clearance Compensating Gear. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 352–353, 5 figs. Gear providing for automatic cancellation of effects of expansion differences.

Design. The Internal Combustion Engine—Fuel, Valves and Ignition, A. W. Bradbury. Trans. Inst. Mar. Engrs., vol. 32, Feb. 1921, pp. 381–404, 14 figs. Design features of typical engines.

Thermodynamic Cycles in Relation to the Design and Future Development of Internal-Combustion Engines, William J. Walker. Jl. Instn. Mech. Engrs., no. 10, Feb. 1921, pp. 1235–1261 and (discussion) pp. 1261–1311, 24 figs. Classification of engine types. Variable specific heat relationship between maximum pressure and mean effective pressure in variable volume cycle. Study based on results obtained in tests of internal-combustion engine, including those operated by coal-gas and producer-gas, oil engines of Diesel and semi-Diesel types, hot-bulb engines and also high-speed gasoline engines of automotive class.

Exhaust-Gas Utilization. The Carbonization of Wood by the Exhaust Gases from Internal Combustion Engines (La carbonisation du bois par l'échappement des moteurs à explosion), Louis Tissier. Chimie & Industrie, vol. 5, no. 2, Feb. 1921, pp. 136–142, 1 fig. Tissier furnace. Exhaust gases pass through pile of wood. High temperature of gases carbonizes wood.

Uses. Internal Combustion Engines, C. S. Darling. Beama, vol. 8, no. 3, Mar. 1921, pp. 248–263, 5 figs. General considerations determining use with reference to power generation.

[See also AEROPLANE ENGINES; AUTOMOBILE ENGINES; DIESEL ENGINES; GAS ENGINES; GAS TURBINES; LUBRICATION, INTERNAL-COMBUSTION ENGINES; OIL ENGINES; SEMI-DIESEL ENGINES; TRACTOR ENGINES.]

IRON

Corrosion-Resisting. The Effect of Copper and Silver Salts on the Corrosion of Iron by Acids, Oliver P. Watts and Harold C. Knapp. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 14, pp. 135–140, 1 fig. Record of tests on corrosion of iron by sulphuric acid in absence or presence of various salts of copper and silver. Conclusion drawn is that in general corrosion is stimulated by presence of these salts.

L

LABOR

Hours of Work. One Year of the Eight-Hour Law in Sweden. Monthly Labor Review, vol. 12, no. 3, Mar. 1921, pp. 97–98. "Confronted with the unsatisfactory results" of 8-hour law Swedish Government has commissioned Royal Social Board to investigate and report upon advisability of modification of its provisions.

LATHE TOOLS

Turret Lathes. Tooling the Modern Turret Lathe, A. H. Lloyd. Can Machy., vol. 25, no. 12, Mar. 24, 1921, pp. 33–36, 9 figs. Tools for machining magneto cam case, gun-metal bush and motorcycle flywheel.

LATHES

Bench. Tools and Methods for Manufacturing Precision Bench Lathes—II. Machy. (N. Y.), vol. 27, no. 8, April 1921, pp. 751–754, 9 figs. Practice of S. A. Potter Tool & Machine Works, New York City, in manufacture of bench lathes.

German Automatic. German Automatic Lathes (Der deutsche Automatenbau), Ph. Kelle. Der praktische Maschinen-Konstrukteur, vol. 54, no. 6, Feb. 10, 1921, pp. 17–32, 47 figs. Details of various types of lathes for the machining of screws and similar parts. It is pointed out that whereas most German automatic lathes are copied from American systems, the described screw lathe is a purely German system constructed exclusively in Germany.

Railway Wheel. A new 5-ft. Railway Wheel Lathe. Machy. (Lond.), vol. 18, no. 443, Mar. 24, 1921, pp. 771–773, 3 figs. Manufactured by W. G. Armstrong, Whitworth & Co., Manchester, England.

Standards. Report of the German Industry Committee on Standards (Mitteilungen des Normenausschusses der Deutschen Industrie). Betrieb, vol. 3, no. 12, Mar. 10, 1921, pp. 159–161, 4 figs. Proposal of the Board of Directors for speed cones. Proposed standards for hand wheels.

Staybolt. A Lathe for Staybolts (Eine Stenbolzen-Drehbank), W. Daevessen. Betrieb, (special no.), vol. 3. no. 11, Mar., 1921, pp. 300–301, 1 fig. Special lathe constructed by the Magdeburger Machine-Tool Factory Corp.

Turret. Large Turret Lathes (Gross-Revolverbänke) Fritz Heilborn. Betrieb (special no.), vol. 3, no. 11, Mar., 1921, pp. 297–299, 3 figs. Type manufactured by Böhringer Bros., Göppingen, Germany, for machining of crankcases. The machining of crankcases of 380 mm. diam. and 200 m. breadth takes about 35 minutes.

LAUNCHING

Tallows for. Some Experiments on Tallows Used for Launching Ships, J. J. King-Salter. Engineering, vol. 111, no. 2883, April 1, 1921, pp. 405–407, 2 figs. Curves of compression strength and hardness factors against temperatures for various natural tallows. Paper read before Instn. Naval Architects.

LIGNITE

Utilization. New Recommendations for the Rational Utilization of Bituminous Wet Lignites (Neue Vorschläge zur rationellen Ausnutzung bituminöser nasser Braunkohle), Gh. Limberg. Braunkohle, vol. 19, no. 46, Feb. 26, 1921, pp. 570–574, 1 fig. Notes on distillation at low temperature for the production of low-temperature coke. (Concluded).

Germany's Brown Coal, Robert G. Skerrett. Sci. Am., vol. 124, no. 16, April 16, 1921, pp. 304 and 315, 2 figs. Industrial utilization of swamp muck.

LOCOMOTIVE BOILERS

Heavy Freight Locomotives. Details of New Santa Fe Locomotive Boilers. Boiler Maker, vol. 21, no. 4, April 1921, pp. 95–100 and 124, 7 figs. Conical design built for working pressure of 195 lb. per sq. in. Outside diameter of course is 88 in., while diameter of rear course is 100 in. Firebox is 132 in. long and 96 in. wide.

LOCOMOTIVES

Bearings. Shop Methods of Casting Locomotive Bearings, J. V. Hunter. Am. Mach., vol. 54, no. 14, April 7, 1921, pp. 590–596, 23 figs. Comparison of methods used in shops of Wabash Railroad, Big Four System and Chicago & Alton Railway.

Belgian. The New "Consolidation" Locomotives of the Belgian State Railways, E. Minsart. Bul. Int. Ry. Assn., vol. 3, no. 3, Mar. 1921, pp. 305–311, 3 figs. Dimensions: Diameter of cylinder, 24 in.; piston stroke, 28 in.; boiler pressure, 199.12 lb.; inside diameter of boiler, 5 ft. 8 in.; heating surface of fire-box, 149.62 sq. ft.; total wheel base of engine, 27 ft. 11 in.

British. 4-6-4 Type Tank Locomotive for the Furness Railway. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 356–357, 6 figs. partly on supp. plate. Characteristics: Cylinders, 19½ in. by 26 in.; wheels, coupled diameter, 5 ft. 8 in.; wheelbase, coupled, 13 ft. 3 in.; heating surface tubes, 1850 sq. ft.; heating surface fire-box, 153 sq. ft.

New Express Locomotives for the Bengal-Nagpur Railway. Ry. Gaz., vol. 34, no. 11, Mar. 18, 1921, pp. 428–429, 3 figs. Characteristics: Type, 4-6-0; cylinders, 21½ in. diameter by 26-in. stroke; diameter of driving wheels, 6 ft. 1½ in.; total evaporative surface, 1259 sq. ft.; superheating surface, 250 sq. ft.; tractive force, 23,554 lb.

Powerful Side Tank "Ghat" Locomotives for the Great Indian Peninsula Railway. Ry. Gaz. vol. 34, no. 12, Mar. 25, 1921, pp. 475, 1 fig. Characteristics: Cylinders, diameter, 22 in.; piston stroke, 26 in.; wheelbase, coupled wheels, 15 ft. 6 in.; weight on coupled wheels, 79 tons 16 cwt.

Coaling Stations. Coaling Station for City Engine Terminal: O. & R. R. Eng. News-Rec., vol. 86, no 16, April 21, 1921, pp. 673–674, 3 figs. Three grades of coal. Operator handles chutes. One hoist service for coal and sand. Large sand drying plant.

Design. Locomotives for Operation on Curves (Bogenläufige Lokomotiven), F. Meineke. Zeit. des Vereines deutscher Ingenieure, vol. 65, nos. 8 and 9, Feb. 19 and 26, 1921, pp. 191–194 and 217–221, 19 figs. Notes on arrangement of the axles in special frames or in main frames; description of the most important modern locomotive types; the Mallet locomotive; the Krauss truck; the Gölsdorf axle arrangement; the Klien-Lindner axles; American 2C1 and 2D1 locomotives; 1D1 four-cylinder compound locomotives of the Saxon State Railroad. Selection of suitable construction types.

Internal-Combustion. Internal Combustion Locomotives for Railway Service. Ry. Gaz., vol. 34, no. 11, Mar. 18, 1921, pp. 440–443, 4 figs. Light locomotives built by Ruston & Hornsby, England. Two types, one 10 hp. and one 20 hp.

Mine, Internal-Combustion. German Internal-Combustion Locomotives. Gas & Oil Power, 16, no. 187, April 7, 1921, pp. 109–110, 3 figs. Mine locomotive built by Deutz Gas Engine Co.

Reconstruction. Locomotives and Locomotive Terminals. Mech. Eng., vol. 43, no. 4, April 1921, pp. 255–258 and 272. Salient points brought out in discussion of papers on increasing capacity of old locomotives and modernizing locomotive terminals, presented at Am. Soc. Mech.Engrs. 1920 annual meeting.

Stoker-Fired. Operating Economies in Longe Runs, F. M. Nellis. Ry. Rev., vol. 68, no. 14, April 2, 1921, pp. 535–536. Experience of Erie Railroad.

Throttle Valve for. Design of an Improved Locomotive Throttle Valve, W. J. Knox. Ry. Mech. Engr., vol. 95, no. 4, April 1921, pp. 216–218, 10 figs. Type developed by Buffalo, Rochester & Pittsburgh Railroad.

LUBRICANTS

Drilling. Investigation of Lubricants for Drilling (Untersuchung von Bohrölen), Georg Schlesinger and Eugen Simon. Werkstattstechnik, vol. 15, no. 5, Mar. 1, 1921, pp. 140–143, 6 figs. Results of investigation carried out at the experimental bureau for machine tools of the Berlin Technical Academy.

LUBRICATING OILS

Reclamation. The Reclamation of Lubricating Oils (La régénération des huiles de graissage). Bulletin technique du Bureau Veritas, vol. 3, no. 3, Mar. 1921, pp. 64–67, 3 figs. Salaün apparatus for reclamation of lubricating oils.

Separators for. Oil Separator (Oljereningsseparatorer). Teknisk Tidskrift (Mekanik), vol. 51, no. 2, Feb. 9, 1921, pp. 37–40, 2 figs. Description of the Alfa Separator AVO. Advantages of centrifugal separation over older processes are pointed out.

Tests. Tests on Lubricating Oil for Two-Stroker Cycle Semi-Diesel Engines, T. M. Robie. Power, vol. 53, no. 15, April 12, 1921, pp. 588–590, 2 figs. Graphs showing influence of temperature on viscosity of lubricating oils.

LUBRICATION

Cylinders. The Lubrication of Steam Cylinders with Oil Emulsions (Schmierung von Dampfzylindern mit Oelemulsionen), H. Hilliger. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 10, Mar. 5, 1921, pp. 248–249, 5 figs. Describes methods and gives results of tests with oils and emulsions, properties and composition of which are given.

Internal-Combustion Engines. The Lubrication of Internal-Combustion Engines (Zur Schmierung der Verbrennungskraftmaschinen), H. Praetorius. Motorwagen, vol. 24, no. 5, Feb. 20, 1921, pp. 90–93, 4 figs. Lubricating pumps of Natter Apparatus Construction Co., Ltd., Feuerbach.

M

MACHINE SHOPS

England. Machine Tool Works at Broadheath Engr., vol. 131, no. 3405, April 1, 1921, pp. 346–347 and 350, 12 figs. Layout of shops. Details of driving arrangements.

MACHINE TOOLS

Efficiency Tests. Factory Valuation of Machine Tools (Zur betriebstechnischen Wertung der Werkzeugmaschine), Alfred Freund. Betrieb (special no), vol. 3, no. 11, Mar. 1921, pp. 319–322. Description and results of efficiency tests carried out on the shaping machines of the F. C. Nischwitz Machine Tool Factory, Halle.

Hydraulic. Hydraulic Machine Tools. Managing Engr., vol. 7, no. 11, Mar. 1921, pp. 201–203, 5 figs. Forging press, cold plate shears, plate flanger, marine boiler riveter, etc. Paper read before Gloucestershire Eng. Soc.

Leipzig Exhibition. Performances of Standard Machine Tools (Einige Leistungen normaler Werkzeugmaschinen), Heinrich Sauter. Betrieb (special no.), vol. 3, no. 11, Mar. 1921, pp. 285–294, 28 figs. Description of principal exhibits.

Reconstruction. Reconstruction of Old Machine Tools for Special Tasks (Umbau alter Werkzeugmaschinen für Spezialarbeiten), Paul Krieg. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 270–272, 2 figs. It is shown that even in the case of mass production it is not always necessary to procure new and expensive special machines, and that equally good or better results can be obtained through skillful reconstruction of existing machines. Example is given of a lathe for copper locomotive-boiler staybolt.

Standardization. Practical Formulas for Small Construction Parts in the Construction of Machine Tools (Praktische Formeln für kleinere Konstruktionsteile im Werkzeugmaschinenbau), H. Lambrette. Der praktische Maschinen-Konstrukteur, vol. 54, no. 8, Feb. 24, 1921, pp. 33–35. It is suggested that formulas given might be of aid in standardization.

Steels for Parts. Steels for Machine Tool Parts, Robert M. Taylor. Machy. (N. Y.), vol. 27, no. 8, April 1921, pps. 770–771. Table of required properties of steel for machine tool parts. (Abstract.) Paper read before Am. Soc. for Steel Treating.

Stud-Inserting Attachment. A New Type of Stud Inserting Machine (Ein neuartiger Stiftschraubeneinzieher), Christian Weiherer. Der praktische Maschinen-Konstrukteur, vol. 54, no. 7, Feb. 17, 1921, pp. 31–33, 3 figs. Describes patented device, called "Rekord," which has been successfully employed in the M.A.N. works in connection with a radial drill for screwing studs in cylinders.

Testing Laboratory. A Testing Laboratory for Machine Tools (Ein Versuchsfeld fur Werkzeugmaschinen), Willi Mitan. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 11, Mar. 12, 1921, pp. 268–269, 4 figs. The electrically driven testing laboratory of the Fritz Werner Corp., Berlin-Marienfelde, for testing the power requirements and efficiency of machine tools and other necessary tools and auxiliary equipment, is provided with four testing motors and a switchboard with measuring instruments and is fed from a converter installation of 30 kw.

MACHINERY

Production Statistics. Statistics of Production in Machine Construction (Produktionsstatistik im Maschinenbau), H. Rech. Betrieb, vol. 3, no. 9, Feb. 10, 1921, pp. 221–230, 3 figs. 2 on supp. plate.

Deals with organization for collecting statistics of production instituted by Assn. of German Machine Builders in 1907. Compilation of results is given in tables showing extent of employment, importance of export, development of prices, operating efficiency, etc., since 1909.

MAGNETS

Steels for. Steels for Permanent Magnets. Elecn. vol. 86, no. 2235, Mar. 18, 1921, pp. 327, 3 figs. Graphs showing magnetic qualities of hecla M. T. steel, Hadfield Research Laboratory, England.

MALLEABLE CASTINGS

Automotive Industry. Malleable Castings Production as Related to the Automotive Industry. Automotive Industries, vol. 44, no. 13, Mar. 31, 1921, pp. 708–711, 1 fig. Technical and commercial development of malleable castings production.

Influence of Manganese on Strength. Influence of Manganese on the Tensile Strength Properties of Malleable Castings (Einfluss des Mangans auf die Festigkeitseigenschaften des schmiedbaren Gusses), E. Leuenberger. Stahl u. Eisen, vol. 41, no. 9, Mar. 3, 1921, pp. 285–287, 3 figs. Results of tests show that with regard to these properties a higher manganese content than 0.4 per cent is permissible the tensile strength increases with increasing manganese content; up to about 1 per cent, manganese has no influence on expansion; etc.

Steel vs. Malleable Castings vs. Grey Iron and Steel, Enrique Touceda. Can. Foundryman, vol. 12, no. 4, April 1921, pp. 26–28, 4 figs. Ability to stand abuse, static and dynamic strength, ease of machining, smoothness of surface. Properties and limitations of malleable-iron castings.

MALLEABLE IRON

Annealing. Anneals Malleable Iron with Oil Fuel, William F. Hoernke. Foundry, vol. 49, no. 8, April 15, 1921, pp. 323–325, 3 figs. Experience of Stowell Co., Milwaukee. Oil is more expensive fuel but requires less labor in handling and firing.

Properties. American Malleable Cast Iron, H. A. Schwartz. Iron Trade Rev., vol. 68, nos. 13 and 15, Mar. 31 and April 14, 1921, pp. 901–904, 8 figs. and 1039–1042, 5 figs. Series of articles dealing with development of industry, modern methods of manufacture, metallurgical principles involved and properties of American malleable iron. Thermal and electrical properties of malleable iron.

MARINE BOILERS

Standard Construction. Standard Conditions for the Design and Construction of Marine Boilers. Steamship, vol. 32, no. 382, April 1921, pp. 239–242. Regulations issued by British Board of Trade. (To be continued.)

MARINE STEAM TURBINES

Reversing. A Description of a New Reversing Turbine. Mar. Eng., vol. 11, no. 1, Jan. 1921, pp. 40–42, 2 figs. Device to regulate steam supply automatically.

METALS

Calorizing. Protecting Metals Against Heat by Calorizing, Arthur V. Farr. Raw Material, vol. 4, no. 3, Mar. 1921, pp. 86–89, 6 figs. Process of calorizing consists in placing material in retort and heating in reducing atmosphere, retort being filled with mixture containing finely divided aluminum. Homogeneous aluminum alloy is formed for certain depth.

Fatigue of. Tests Support Theory of Fatigue, H. F. Moore. Iron Trade Rev., vol. 68, no. 13, Mar. 31, 1921, pp. 895–897, 3 figs. Experiments conducted on metals which were subjected to alternate and repeated strains showed that failure from fatigue is due largely to growth of minute flaws.

Properties. Physical Properties of Materials. U. S. Dept. of Commerce, Circular of Bur. of Standards, no. 101, Feb. 9, 1921, 52 pp. Strengths and related properties of metals and other engineering materials. Revision of Smithsonian physical tables.

METRIC SYSTEM

Compulsory Adoption in Japan. The Compulsory Adoption of the Metric System in the Japanese Empire (L'adoption obligatoire du système métrique par l'empire du Japan), Ch.-Ed. Guillaume. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 13, Mar. 29, 1921, pp. 795–796. Comment on significance of recent sanction by Japanese parliament of law making compulsory the use of the metric system in the Japanese empire.

MILLING

Gang Milling. Gang Milling. Eng. Production, vol. 2, no. 24, Mar. 17, 1921, pp. 342–345, 14 figs. Notes on cutters employed and their arrangement.

MILLING CUTTERS

Teeth, Spacing of. Metal Cutting Tools—VIII, A. L. DeLeeuw. Am. Mach., vol. 54, no. 15, April 14, 1921, pp. 635–640, 16 figs. Spacing of teeth of milling cutters.

MILLING MACHINES

Automatic. A New Automatic Miller. Eng. Production, vol. 2, no. 24, Mar. 17, 1921, pp. 340–341, 5 figs. Machines intended for manufacture of duplicating parts in large quantities. Spindle and table are controlled automatically. Manufactured by Buck and Hickman, London.

Continuous. Continuous milling, J. H. Moore. Can. Machy., vol. 25, no. 14, April 7, 1921, pp. 65–68, 9 figs. Rotary and reciprocating types of continuous milling machines.

High-Power. Rockford Milling Machine. Iron Age, vol. 107, no. 16, April 21, 1921, pp. 1039–1040, 2 figs. High-power, all-geared, single-pulley milling machine recently brought out by Rockford Milling Machine Co., Rockford, Ill. Rectangular overarm moved by rack and pinion. Single control for feed and quick return.

Rockford No. 3 "High-Power" Milling Machine, J. V. Hunter. Am. Mach., vol. 54, no. 14, April 7, 1921, pp. 585–587, 5 figs.

MOLYBDENUM

Norway. The Molybdenum Mines of Norway (Norske molybdengruber), Otto Falkenberg. Teknisk Ukeblad, vol. 68, no. 1, Jan. 7, 1921, pp. 6–11, 15 figs. Occurrences and properties of molybdenum, Norway has only specular molybdenum ore. Notes on production and treatment mainly in Elmore apparatus. It is used in chemical industry, but chiefly with alloyed steels. Prospects.

MOTION-PICTURE PHOTOGRAPHY

200,000 Photographs per Minute. Two Hundred Thousand Photographs per Minute, C. H. Claudy. Sci. Am., vol. 124, no. 15, April 9, 1921, pp. 288–297 and 299, 6 figs. High-speed motion-picture projectors and camera which makes use of prisms instead of usual shutter and intermittent movement mechanism.

MOTOR PLOWS

Tests. Factors Influencing the Draft of Plows, E. V. Collins. Agricultural Eng., vol. 2, no. 2, Feb. 1921, pp. 27–29, 7 figs. Records of tests.

MOTOR-TRUCK TRAFFIC

Legislation. How Maryland Enforces Its Motor Vehicle Law. Eng. News-Rec., vol. 86, no. 16, April 21, 1921, pp. 666–668, 3 figs. Truck weights checked by scales and loadometers. Ten tons limit. Excess loads deposited at roadsides.

Refrigerated Transport. Road Traction for Refrigerated Transport, H. M. Dunkerley. Cold Storage & Ice Assn., vol. 17, no. 1, 1920–1921, pp. 25–36 and (discussion) pp. 37–47, 3 figs. on 2 supp. plates. Requirements of vehicles used in transporting refrigerated product.

MOTOR TRUCKS

Maintenance. The Care and Maintenance of Motor Trucks, N. J. Smith. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 331–334. Practice of Consumers Co., which operates 159 motor trucks for delivering coal, ice and other supplies in territory covering city of Chicago and outlying districts.

Trailers. How to Apply Trucks and Trailers Under Given Load and Road Conditions, Marius C. Krarup. Automotive Industries, vol. 44, no. 12, Mar. 24, 1921, pp. 654–658, 5 figs. Table giving drawbar pull obtainable at speeds from 1 to 20 m.p.h. from net horsepower available at rims of driving wheels. Graph of resistances to vehicle movements due to grades and irregular or soft road surfaces.

MOTORSHIPS

Two-Cycle vs. Four-Cycle Engines. Two Versus Four Cycle Diesel Engines. Mar. Eng., vol. 26, no. 4, April 1921, pp. 321–323, 2 figs. Competition between manufacturers of two types in Europe.

N

NICKEL

Electrolytic. Ductile Electrolytic Nickel, Chas. P. Madsen. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 23, pp. 269–276. Experiments confirming writer's discovery that if cathodes in nickel electrolytic bath are periodically lifted out of bath, exposed to air, and reimmersed within certain limiting time, nickel deposit does not laminate but is greatly improved as regards freedom from pitting and mechanical properties.

The Use of Fluorides in Solutions for Nickel Deposition, William Blum. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 21, pp. 227–247, 3 figs. Discusses factors governing deposition of hard deposits of nickel from solutions containing fluorides, with and without boric acid and other salts. General principles of getting good deposits are discussed, showing that low acidity favors good nickel deposition, but high acidity good anode corrosion. Bearing of hydrogen-ion concentration on matter is explained.

NICKEL ALLOYS

Compositions, Properties, Uses. Miscellaneous Alloys of Nickel, Paul D. Merica. Chem. & Metallurgical Eng., vol. 24, no. 15, April 13, 1921, pp. 649–653. Principal data on binary alloy systems with nickel as one constituent. Use of nickel in bronzes and light aluminum alloys. Composition and electrical characteristics of many special resistance alloys. Analyses of complex alloys for various minor uses.

OFFICE BUILDINGS

Reinforced-concrete. Construction Detail of General Motors Office Building, Joseph Matte, Jr. Eng. News-Rec., vol. 36, no. 15, April 14, 1921, pp. 625–630, 12 figs. Fifteen-story structure with thirty-two acres of floor space to house 6000 persons. Heavy girders and columns in steel frame. Reinforced-concrete laborator building.

OIL ENGINES

Densil. A Serviceable Crude-Oil Engine. Steamship, vol. 32, no. 382, April 1921, pp. 251–253. Densil single-cylinder engine of hot-bulb type, with additional water-cooled head distinct from cylinder and bulb.

Marine. Reversing of Marine Oil Engines, Walter Pollock. Trans. Inst. Mar. Engrs., vol. 32, Feb. 1921, pp. 347–380, 10 figs. Classification and description of reversing systems in use.

OIL FIELDS

Argentina. The Petroliferous Region of Cacheuta (La región petrolífera de Cacheuta), Guillermo Hileman. Ingeniería Internacional, vol. 5, no. 5, May 1921, pp. 286–289, 3 figs. Geological description of and account of prospecting operations in Argentina region.

Australia. The Possibility of Oil Discovery on the Mainland of Australia, Wm. Clarkson. Petroleum Times, vol. 5, no. 114, Mar. 12, 1921, pp. 309–311. Conditions essential to occurrence of oil in quantity. Prospecting experiences in Australia.

Borneo. The Crude Oils of Borneo, James Kelway. Petroleum Times, vol. 5, no. 115, Mar. 19, 1921, pp. 33/-339. Geological and chemical notes.

Canada. Oil Possibilities of the Mackenzie—A Warning. Eng. & Min. Jl., vol. 111, no. 13, Mar 26, 1921, pp. 553–554. It is said oil dissipation has taken place and transportation is a serious problem.

OIL FUEL

Burners. Oil Fuel Burners Insuring Complete Preliminary Combustion of Liquid (Brûleur à combustion complete préalable, pour combustibles liquides). Génie Civil, vol. 78, no. 13, Mar. 26, 1921, p. 279, 1 fig. Air and pulverized fuel are thoroughly mixed and ignited in special chamber before passing into furnace proper.

Flue-Gas Analyses with. Records of Flue Gas Analyses with Fuel Oil, L. J. Goodrich. Power Plant Eng., vol. 25, no. 7, April 1, 1921, pp. 366–367, 2 figs. Calculation of fuel losses from flue-gas analyses and moisture contents of fuel and air.

Stowing on Board Ship. Hydraulic System for Stowing and Handling Fuel Oil on Board Ships in Yards or Docks. Mar. Eng., vol. 26, no. 4, April 1921, pp. 304–305, 1 fig. Adaptation of hydraulic system for control of oil fuel of large dredge.

Uses. Fuel Oil, W. A. White. Trans. North-East Coast Instn. Engrs. & Shipbuilders, vol. 37, part 4, Feb. 1921, pp. 209–238, 4 figs. Estimated petroleum deposits of the world. Statistics of production and transport of oil fuel. Typical oil-fuel storage station. Uses of oil fuel.

Uses of Oil Fuel (Emploi des combustibles liquides. M. Pillard. Arts et Métiers, vol. 74, no. 4, Jan. 1921, pp. 3–9, 4 figs. Tests on use of oil fuel in industrial furnaces.

OIL INDUSTRY

Canada. Canada a Vast Storehouse of Oil Resources, Earle W. Gage. Gas Engine, vol. 23, no. 4, April 1921, pp. 85–87. Canada's annual oil production, according to government statistics, amounts to nearly 310,000 bbl. 90 per cent from Ontario fields.

Poland. Petroleum Industry in Poland. Min. & Oil Bul., vol. 7, no. 4, Mar. 1921, pp. 219–221, 4 figs. Output of fields has reached level of about 842,000 barrels a month.

United States. America's Petroleum Problem, J. O. Lewis Jl. Franklin Inst., vol. 191, no. 3, Mar. 1921, pp. 357–379. Probable duration of oil supply in U. S. taking into account continuously increasing rate of consumption of oil. No exhaustion for many generations is apprehended.

OIL SHALES

Colorado. Studies in Colorado Shale Oils, Arthur J. Franks. Chem. & Metallurgical Eng., vol. 24, no. 13, Mar. 30, 1921, pp. 561–564, 2 figs. Lighter hydrocarbon oil fractions found to be more saturated than heavier fractions. Methods used in obtaining data. Graphical analysis of distillation cuts, showing temperatures, saturation and specific gravities.

Scotland. The Necessity for Research in the Oil-Shale Industry, Martin J. Gavin. Sci. & Industry, vol. 2, no. 12, Dec. 1920, pp. 746–760, 4 figs. Account of shale-oil industry as developed in Scotland. Steam-regulated pyrolytic distillation. Quality and quantity of oil yields.

OPEN-HEARTH FURNACES

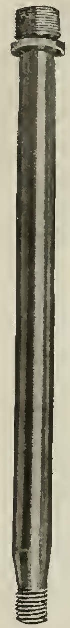
Controlling Valve. New Controlling Valve for Open Hearths, W. H. Wharton. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 253 and 280, 1 fig. Reversing valve combined with air-pressure and volume-controlling mechanism.

Fluorspar Addition. The Use of Fluorspar in Open-Hearth Furnaces (Ueber die Verwendung von Flussspat in Martinöfen), S. Schleicher. Stahl u. Eisen, vol. 41, no. 11, Mar. 17, 1921, pp. 357–361 and (Discussion) pp. 362–364, 2 figs. It is pointed out that if fluorspar is added to an open-hearth slag it decomposes only to a certain extent; fluorspar has a desulphurizing effect in that the sulphur is volatilized from the slag in any desired form so that the slag can re-absorb sulphur from the bath.

OXY-ACETYLENE WELDING

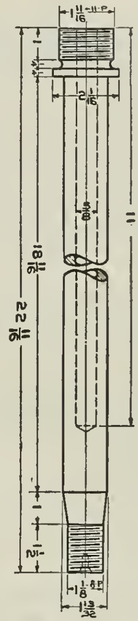
Plate-Steel Roof. Oxy-Acetylene Welding and Cutting at Anaconda, Thomas W. Cunningham. Min. & Sci. Press, vol. 122, no. 13, Mar. 26, 1921, pp. 425–426. Welding of plate-steel roof of metallurgical mill.

The Best Production Methods Are the Most Economical



There is only one *best* method in turret lathe practice. Our Engineers are constantly studying and experimenting to reach that best method and keep our turret lathes up to their high standard.

The results of their study and experimenting are yours to apply to your production problems. Just write us and we'll send one of our engineers to consult with you. He may be able to save you considerable money by suggesting a tool or two or perhaps by re-arranging the tools you have. This is part of our service to you.



Turret Lathes from 4½" x 44"—21" Swing to ⅝" x 4"—10" Swing.

A. W. & S. No. 3-A finishes one of these Air Brake Pump Pistons of cold rolled stock every 20 minutes in an eastern railroad shop. This is a difficult railroad job.

ENGINEERING INDEX (Continued)

Pressure Vessels. Oxy-Acetylene Welding and Cutting, P. E. Willis. Jl. Engrs. Club of St. Louis, vol. 6, no. 1, Jan.-Feb.-Mar. 1921, pp. 13–28. Uses of oxy-acetylene welding torch. Its application to welding of pressure vessels.

P

PAPER MANUFACTURE

Size Standardization. Standardization of Sizes in the Manufacture of Paper. Paper, vol. 27, no. 27, Mar. 16, 1921, pp. 9–10 and 36. List of proposed standards.

PEAT

Minnesota. Experimental Work on Minnesota Peat Soils, F. J. Alway. Jl. Am. Peat Soc., vol. 14, no. 2, April 1921, pp. 40–47, 2 figs.

Utilization. The Manufacture and Utilization of Peat Fuel, Benj. F. Haanel. Jl. Am. Peat Soc., vol. 14, no. 2, April 1921, pp. 1–25, 3 figs. Curve showing effect on calorific power of wet peat by removing different percentages of total moisture content. Investigation on rate at which drying takes place during operating period. Paper read before Am. Inst. Chem. Engrs.

PIERS

Concrete. Oil Protects Concrete Piers from Sea Water Action, Contract Rec., vol. 35, no. 11, Mar. 16, 1921, pp. 268–272, 8 figs. Examination of test specimens immersed since 1909 shows them covered with tar-like coating which prevents corrosion. Rich wet mixes seem least affected by salt water.

PIG IRON

Manufacture. Foundry Pig Iron in Birmingham District, Y. A. Dyer. Iron Age, vol. 107, no. 14, April 7, 1921, pp. 907–909, 3 figs. Trend towards use of machine-cast pig by foundries. Claimed advantages over sand-cast iron include lower melting point.

PILES, CONCRETE

Sea Water, Action of. The Action of Sea Water on Concrete Piles. Contract Rec., vol. 35, no. 12, Mar. 23, 1921, pp. 288–291, 6 figs. Analysis of tests carried out by Aberthaw Construction Co. during past twelve years.

PIPE BENDS

Soft Steel. Pipe Bends (Rohrbogen). Autogene Metallbearbeitung, vol. 14, no. 4, Feb. 15, 1921, pp. 54–59, 26 figs. Describes low-carbon-steel pipe bends manufactured according to a patented process in different curve radii of one-quarter to three-quarter arc and representing finished manufactured articles produced by the Pipe Bend Works, Ltd., Hamburg.

PIPE CONCRETE

Tests. Test Concrete Pressure Pipe With Encased Steel Diaphragm. Eng. News-Rec., vol. 86, no. 15, April 14, 1921, pp. 645–646, 3 figs. Inside of reinforced-concrete shell is 3/16-in. steel pipe which is welded at joints between cast sections.

PIPE, IRON

Strength. Collapsing Strength of Iron Pipes and Tubes, W. F. Schaphorst. Power Plant Eng., vol. 25, no. 8, April 15, 1921, pp. 431. Chart for determining collapsing of iron pipes.

PIPE, STEEL

Spellerized. Spellerized Steel Piping. Power, vol. 53, no. 13, Mar. 29, 1921, pp. 513, 1 fig. Spellerizing process consists of passing heated bloom through rolls and reducing it to proper dimensions for finished product. Spellerizing rolls have regularly shaped projections on their working surface.

PIPE, WROUGHT IRON

Manufacture. Manufacture of Wrought Pipe for High Pressures. Machy. (N. Y.), vol. 27, no. 8, April 1921, pp. 755–756, 5 figs. Practice of National Tube Co., Pittsburgh.

PLANING

Production Systems. Production Planing in Machine Tool Plants. Machy. (Lond.), vol. 17, nos. 442 and 444, Mar. 17 and 31, 1921, pp. 747–752, 8 figs., and 793–797, 7 figs. Methods used in shops of representative planer and engine-lathe builders.

Production Planing in Machine Tool Plants—V. Machy. (Lond.), vol. 17, no. 444, Mar. 31, 1921, pp. 793–797, 7 figs. Methods used in planer-building shops.

PLATES

Stresses in. Contact Pressures and Stresses, E.G. Coker, K. C. Chakko and M. S. Ahmed. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 373–376, 10 figs. Analytical study of stress distribution in plate around point at which concentrated load is applied. Experimental confirmation of analytical results. (To be continued.) Paper read before Instn. Mech. Engrs.

PRESSES

Industrial. Penkala Presses for Compression of Materials and Extraction of Liquids Therefrom (Presses système Penkala, pour l'agglomération des matières et pour l'extraction des liquides qui y sont contenus), M. Biver. Génie Civil, vol. 78, no. 13, Mar. 26, 1921, pp. 265–267, 4 figs. Types of industrial presses, particularly presses used for extraction of juice from cane sugar.

PROPELLERS, SHIP

Design. The Evolution of a New Type of Propeller, H. W. Gill. Mar. Eng., vol. 11, no. 1, Jan. 1921, pp. 17–22, 9 figs. Four-bladed vortex-type propeller protected by outside rim.

Tests. The Screw Propeller—II. Supplément au bulletin technique du Bureau Veritas, Mar. 1921, pp. 9–16, 4 figs. Results of experiments on model propellers with elliptical blades and with wide, deep blades.

Thacher Molding Process. Thacher Molding Process for Propeller Wheels and Blades, Enrique Touceda. Trans. Am. Inst. Min. & Metallurgical Engrs., advance paper, 12 pp. 9 figs. Method developed by Geo. H. Thacher & Co., Albany, N. Y., for rapid manufacture of marine and other gray-iron castings. No subsequent machining is required on blades of propellers.

PROTECTIVE COATINGS

Metal Paints. Metal Protective Paints, Henry A. Gardner. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 11, pp. 85–87. Chemical classification of substances used as paints on metallic structures.

PULVERIZED COAL

Gasification. Gasification of Powdered Coal, A. E. Bourcoud. Chem. & Metallurgical Eng., vol. 24, no. 14, April 6, 1921, pp. 600–604, 4 figs. Consideration of velocity with which reaction takes place between producer gas and suspended carbon, using results for estimating proposal for gasifying powdered coal or oil.

Systems of Burning. Powdered Fuel, Robert James, Proc. So. Wales Inst. Engrs., vol. 37, no. 1, Mar. 10, 1921, pp. 73–110, 18 figs. Systems of burning pulverized coal. Use of pulverized coal in boiler furnaces, locomotives, marine boilers, etc.

Uses. Metallurgical Use of Pulverized Fuel, C. F. Herington. Iron Age, vol. 107, no. 15, April 14, 1921, pp. 965–969, 4 figs. Advances made in utilization of powdered coal as fuel in metallurgical furnaces. List of plants and equipment. There are approximately 2000 metallurgical furnaces using pulverized coal. Plants listed are principally in U. S. and Canada.

PUMPS

Air-Lift. Air-Lift Pumps—Information Required for Design, R. M. Anderson. Stevens Indicator, vol. 37, no. 4, Oct. 1920, pp. 249–269, 10 figs. Formulas, graphs and tables.

PYROMETERS

Platinum-Resistance. Recent Modifications in the Construction of Platinum Resistance Thermometers, T. S. Sligh, Jr., Dept. of Commerce, Sci. Papers, Bur. of Standards, no. 407, Jan. 5, 1921, pp. 49–63, 2 figs. Survey of developments in construction of resistance thermometers as regards heads, leads, terminals and sealing of strain-free type. Elimination of drying head and use of all-metal case with calorimetric type of resistance thermometer.

R

RAILS

Creeping. Rail Creep. Ry. Gaz., vol. 34, no. 11, Mar. 18, 1921, pp. 430–432, 4 figs. Analysis of causes and effects of rail creeping and description of anti-creep anchors.

French Standard. Standard Rails and Splice Bars on French Railways. Eng. News-Rec., vol. 86, no. 11, Mar. 17, 1921, p. 473, 1 fig. Standard rails recommended by commission of engineers appointed at conference between French minister of war and heads of railway systems. Translated from Revue générale des Chemins de Fer.

RAILWAY ELECTRIFICATION

Austria. The Electrification of the Arlberg Railway (Die Elektrifizierung der Arlbergbahn), A. Marschall. Elektrotechnische Rundschau, vol. 38, no. 3, Feb. 7, 1921, pp. 15–16. Notes on the Spuller Lake power station under construction which is the largest railway power station in new Austria and technically one of the most important plants in Europe. Details of equipment and construction.

Economic Advantages. Electrification Reviewed from the Standpoint of Service. C. C. Whittaker. Ry. Rev., vol. 68, no. 13, Mar. 26, 1921, pp. 483–487, 4 figs. Operating advantages resulting from substitution of electricity for steam in railway service. Paper presented before Providence Eng. Soc.

The Economic Aspects of Railway Electrification A. H. Armstrong. Jl. Franklin Inst., vol. 191, no. 4, April 1921, pp. 493–502. Economic advantages of railway electrification, principally from aspect of future growth of transportation system of country and its effect upon national transportation.

France. French Railways Electrification. Elec. Ry. & Tramway Jl., vols. 43 & 44, nos. 1055, 1060, 1064 and 1068, Dec. 10, 1920, Jan. 14, Feb. 11, Mar. 11, 1921, pp. 280–282, 17–19, 61 and 105–107. Official report issued by Ministère des Travaux Publics, containing full details of proceedings of Comité d'Etudes for electrification of systems of great railways as well as various decisions which have been arrived at in respect of lines to be electrified, sources of hydroelectric power, systems of generation and distribution, volatge and frequency, methods of current collection, types of electric locomotives, costs of establishment and operation, and other cognate matters.

India. The Electrification of Indian Railways—III. Ry. Engr., vol. 42, no. 494, Mar. 1921, pp. 92–97, 15 figs. Advantage of using electric locomotives as compared with steam locomotives on heavily graded sections of North Western Ry. of India.

RAILWAY REPAIR SHOPS

Machining Locomotive Parts. Railway Machine Shop Practice—I, Edward K. Hammond. Machy. (N. Y.) vol. 27, no. 8, April 1921, pp. 721–729, 17 figs. Methods employed in railway repair shops for machining locomotive parts.

RAILWAY SHOPS

Sheet-Metal Work. Sheet-Metal Shop Equipment for Railroad Work, J. V. Hunter. Am. Mach., vol. 54, no. 16, April 21, 1921, pp. 683–686, 11 figs. Typical modern power shears, presses and brakes.

RAILWAY SIGNALING

Interlocking. A New Idea in Traffic Locking on the C. & O., H. E. Johnson. Ry. Signal Engr., vol. 14, no. 4, April 1921, pp. 129–131, 7 figs. Traffic-locking scheme developed in order to increase track capacity on congested portions of road.

Non-Interlocking. Non-Interlocking Non-Stop Grade Crossings, L. B. Porter. Ry. Signal Engr., vol. 14, no. 4, April 1921, pp. 144–147, 3 figs. Proposed signal layout to control train movements automatically at intersection points to prevent train stops.

RAILWAY TIES

Steel. Steel Sleepers on the North Eastern Railway. Ry. Gaz., vol. 34, no. 12, Mar. 25, 1921, p. 476, 3 figs. Trial of steel ties under main-line traffic conditions.

RAILWAY TRACK

Buffer Stops. Hydraulic Buffer Stops. Practical Engr., vol. 63, no. 1780, April 7, 1921, pp. 214–216, 4 figs. Buffers suitable for trains weighing up to 500 tons approaching at speed of 10 miles per hour. Stroke of buffer is 8 ft.

RAILWAYS

Light. On the Question of Safety Appliances on Light Railways. Subject XX for Discussion at the Ninth Congress of the International Railway Association, Serge de Kareischa. Bul. Int. Ry. Assn., vol. 3, no. 3, Mar. 1921, pp. 247–304. Report based on answers received from 63 railways in different countries, operating 75 lines.

Pan-American. Intercontinental Pan-American Railway (Fer ocarril International Pan-Americano), Juan A. Briano. Ingenieria, vol. 24, no. 5, Feb. 1, 1920, pp. 99–103. Advocates construction of Peruvian railways with a view to facilitate establishment of Pan-American intercontinental railway. (To be continued.)

REDUCTION GEARS

Double. Mechanical Gears, of Double Reduction, for Merchant Ships, R. J. Walker and S. S. Cook. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 369–370, 3 figs. Graphs showing torque variation at gear wheel end of propeller shaft determined in experiments on S. S. San Fernando. Paper read before Instn. Naval Architects.

REFRIGERATING MACHINES

Ethyl Chloride. The Ethyl Chloride Refrigerating Machine, Charles Bishop. Cold Storage & Ice Assn., vol. 17, no. 1, 1920–1921, pp. 51–63 and (discussion) pp. 64–71, 4 figs. on 4 supp. plates. Installation of Clothel system in Canadian ships.

RESEARCH

Industrial. The Coöperation of Scientific and Industrial Research in the Iron Foundry, Thos. Vickers. Foundry Trade Jl., vol. 23, no. 241, Mar. 31, 1921, pp. 288–290. Economic advantage of coöperation. (To be continued.) Paper read before Instn. British Foundrymen.

Industrial, Belgium. Organization of Scientific and Industrial Research in Belgium (Organisation de la recherche scientifique et industrielle en Belgique), Edgar Forgeur. Revue universelle des Mines, vol. 8, no. 6, Mar. 15, 1921, pp. 501–522, 1 fig. Suggested scheme for national organization under Central Board of Control.

Scientific. Promotion of Scientific Research, William Hoskins and Russell Wiles. Chem. & Metallurgical Eng., vol. 24, no. 16, April 20, 1921, pp. 689–691. Outline of program for forwarding research in chemical and physical sciences at universities. Industries licensed under patentable discoveries to pay reasonable royalties for support of further research.

ROADS

Subgrades. Investigations of Road Subgrades, A. T. Goldbeck. Jl. Soc. Automotive Engrs., vol. 8, no. 4, April 1921, pp. 339–346, 7 figs. Tests being conducted by Bur. of Public Roads.

ROLLING MILLS

Mannesmann Process. Mannesmann Process Rolling Machinery. Carl Gruber. Iron Age, vol. 107, no. 16, April 21, 1921, pp. 1049–1052, 13 figs. Design of rolling mill and its machinery. Details of adjustment devices and guides and of mandrel. (To be continued.) (Abstract.) Translated from Stahl und Eisen.

Sheet Mills. Drive is Feature of Sheet Mill, John D. Knox. Iron Trade Rev., vol. 68, no. 16, April 21, 1921, pp. 1099–1105 and 1111, 20 figs. Roughing rolls driven by friction gears at plant of Superior Sheet Steel Co., Canton, O. High-speed motors with automatic control are provided. Individual squaring shears serve each hot mill.

When you need legal advice you consult a lawyer.

When you need advice on combustion problems why not consult a combustion engineer?

Selection of furnace equipment is a science in itself. Too many have found this to be true at the expense of much time, money and materials.

Replacements are costly. When you realize that a large percentage of our business is for replacements, then you grasp the significance of having an expert in the first place prescribe the equipment most suitable for your plant.

The sales work of the Sanford Riley Stoker Company and the Murphy Iron Works is in the hands of experienced combustion experts. Located at many central points, these engineers stand ready to give constructive service regarding the operation of present equipment as well as making recommendations on new equipment.

Get in touch with our representatives in your territory. Their services are cheerfully and freely given. Let them save you time, money, men and fuel.

Other Western representatives for Riley Stokers and Murphy Furnaces are:-

Robinson, Cary & Sands Co.,
St. Paul, Minn.

Beeson Machinery Co.,
Kansas City, Missouri

Stearns-Roger Mfg. Co.,
Denver, Colorado

RILEY UNDERFEED STOKERS
MURPHY AUTOMATIC FURNACES

ENGINEERING INDEX (Continued)

St. Louis. Scullin Steel Company's New Mills, F. B. Menner. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 260–261. Installation designed to produce wide range of billets, merchant bars and structural shapes.

RUDDERS

Design. The Design of Balanced Rudders of the Spade Type, M. E. Denny. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 370–373, 5 figs. Formulas for determining diameter of stock required to deal with bending and twisting moments and power of steering engine adequate to operate rudder, and determination of longitudinal position of stock relative to rudder area. Paper read before Instn. Naval Architects.

S

SAWS

Circular. A New Cold Circular Saw Machine (Eine neue Kaltkreissägemaschine), Eduard Müller. Betrieb (special no.), vol. 3, no. 11, Mar., 1921, pp. 316–319, 9 figs. "Gnwa" cold circular saw manufactured by the Gustav Wagner Machine Factory, Reutlingen, Germany, which is said to combine increased efficiency with diminished consumption of power; it operates with four cutting speeds and twelve cutting widths.

SCIENTIFIC MANAGEMENT

See INDUSTRIAL MANAGEMENT.

SCREW MACHINES

Automatic. Magazine Feeds for Automatic Screw Machines. Machy. (Lond.), vol. 18, no. 443, Mar. 24, 1921, pp. 757–762, 10 figs. Special equipments developed by Cleveland Automatic Machine Co., for handling second-operation work.

Producing 900 Float Valve Seats Every Hour, J. H. Moore. Can. Machy., vol. 25, no. 15, April 14, 1921, pp. 25–28, 8 figs. Automatic procedure in making spark plug shells, carburetor float valve seats, piston wrist pins, transmission bolts, sewing machine screws, cylinder priming bodies and nuts in quantity.

SCREW THREADS

National Screw Thread Commission. Progress Report of the National Screw Thread Commission. Dept. of Commerce, Bur. of Standards, no. 42, Jan. 4, 1921, 109, pp. 44 figs. National Screw Thread Commission was created by Act of Congress approved July 18, 1918, for the purpose of ascertaining and establishing standards for screw threads for use of the various branches of the Federal Government and for the use of manufacturers. Report recommends certain systems of threads, and gives information, data and specifications pertaining to manufacture of threads recommended.

SEMI-DIESEL ENGINES

Beardmore. The Beardmore Semi-Diesel Oil Engine. Mar. Eng., vol. 11, no. 3, Mar. 1921, pp. 17–20, 16 figs. Four-cylinder unit manufactured by William Beardmore & Co., Glasgow. Ignition is effected by hot bulb.

Tuxham. The Semi-Diesel Engine (Le moteur semi-Diesel). Revue de l'Ingénieur, vol. 28, no. 2, Feb. 1921, pp. 69–77, 4 figs. Description of Tuxham motor built at Delaunay-Belleville works.

SHAFTS

Standardization. Standard Shaft versus Standard Hole (Einheitswelle oder Einheitsbohrung?). Betrieb, vol. 3, no. 13, Mar. 25, 1921, pp. 181–184. Report of sub-committee before the working committee for allowances of the German Industry Committee on Standards (NDI).

Stresses in. Graphical Method of Computing Stresses in Shafts of Electric Machines Rotating Between Three Bearings (Complément aux méthodes graphiques de calcul des flèches arbres des machines électriques à trois paliers), P. Durand. Revue générale de l'Électricité, vol. 9, no. 11, Mar. 12, 1921, pp. 369–370, 7 figs. Formulas for computing stresses in vertical shaft.

Tests. Torsion and Torsion Tests of Shafts, Arthur G. Robson. Practical Engr., vol. 63, no. 1779, Mar. 31, 1921, pp. 196–198, 2 figs. Interpretation of results of tests.

SHEARING MACHINES

Plate. The Modern Methods of Shearing Plates. (Neuzeitliche Blechbearbeitung), H. Graichen. Betrieb, (special no.), vol. 3, no. 11, Mar., 1921, pp. 313–316, 6 figs. Describes a number of plate-shearing machines and summarizes requirements which such machines must fulfill.

Rotary. Rotary Shearing Machines. Engineering, vol. 111, no. 2882, Mar. 25, 1921, p. 353, 4 figs. Machines constructed by Tangent Tool Co., Somerset, England.

SHIP DESIGN

Speed, Depth of Water and. The Influence of the Depth of Water on the Speed of Ships. Engr., vol. 131, nos. 3404 and 3405, Mar. 25, and April 1, 1921, pp. 309–311, 2 figs. and 340–342, 4 figs. Records of experiments conducted by British Admiralty. Survey of literature. Calculations.

SHIP PROPULSION, ELECTRIC

U. S. S. Tennessee. Propelling Machinery of the U. S. S. Tennessee. Mar. Eng., vol. 26, no. 4, April 1921, pp. 269–273, 7 figs. Latest American battleship driven by electricity generated in Westinghouse turbine generators delivering 40,000 hp.

SHIP SALVAGING

Italian Battleship. The Salving of the Italian Battleship Leonardo da Vinci. Engr., vol. 131, no. 3403, Mar. 18, 1921, pp. 281–283, 16 figs. partly on supp. plate. As result of explosion battleship sank in six fathoms of water. Holes in sides were patched and large number of compartments in ship were rendered airtight under water. Battleship has overall length of 650 ft. and displacement of 22,280 tons.

SHIPBUILDING

Manufacturing Methods. Methods in a Shipbuilding Plant, Fred H. Colvin. Am. Mach., vol. 54, no. 16, April 21, 1921, pp. 672–676, 14 figs. Special machines used by Union Iron Works Plant of Bethlehem Shipbuilding Co., together with work-holding fixtures and labor-saving appliances.

Systems of Construction. A Study of the Framing of a Ship, T. B. Abell. Engineering, vol. 111, no. 2882, Mar. 25, 1921, pp. 376–378, 7 figs. Suggested system of construction. Pillars at middle line or two rows of closel spaced pillars. Paper read before Instn. Naval Architects.

SHIPS

Welded. An Entirely Electrically Welded Vessel. Mar. Eng., vol. 26, no. 4, April 1921, p. 277, 1 fig. Vessel was completed at works of Elektriska Svetsnings Aktiebolaget, Gothenburg, Marieholm, Sweden. Dimensions: Length, 52 ft. 6 in.; breadth, 13 ft. 1 in.; depth molded, 7 ft.; draft, 3 ft. 6 in.

SHIPS, CONCRETE

Construction. Lossier System of Constructing Sea-Going Reinforced-Concrete Vessels at Dufour Shipyard, Paris (Les chalands de mer en béton armé système Henry Lossier, construits aux chantiers Dufour, à Harfleur), Robert Sauser. Génie Civil, vol. 78, no. 11, Mar. 12, 1921, pp. 225–230, 15 figs. Characteristics: Length between perpendiculars, 50 meters; width, 10.65 meters; draft, 6.40 meters; displacement, 1000 tons.

SHOP COMMITTEES

Whitley Councils. The Functions of a Work's Council. Eng. & Indus. Management, vol. 5, no. 14, April 7, 1921, pp. 405–408. Scheme in operation at factory of Cadbury Bros., Birmingham, England.

SLIDE RULES

Vector Type. The Vector Slide-Rule, A. F. Zahn. Jl. Franklin Inst., vol. 191, no. 4, April 1921, pp. 525–528, 2 figs. Slide rule for finding magnitude and line resultant when its combination and its moment about a point are given.

SOOT BLOWERS

Tests. Development of Mechanical Soot Blowers, Robert June. Blast Furnace & Steel Plant, vol. 9, no. 4, April 1921, pp. 275–279, 6 figs. Tests of mechanical soot blowers with coal, pulverized fuel and oil.

Tests of Mechanical Soot Blowers, Robert June. Textile World, vol. 59, no. 14, April 2, 1921, pp. 111–115, 4 figs.

SPRINGS

Helical. Charts for the Calculation of Helical Springs (Tafeln zur Berechnung von zylindrischen Schraubenfedern), Adolf Maydell. Dinglers polytechnisches Jl., vol. 336, no. 3, Feb. 12, 1921, pp. 41–42, 2 figs.

Design of Helical Springs, Joseph Kaye Wood. Am. Mach., vol. 54, no. 15, April 14, 1921, pp. 628–632, 4 figs. Alignment chart for determining spring size.

STAMPING

Thin Steel Plates. Stamping Tests of Thin Steel Plates (Essai a l'emboutissage des tôles minces), Ch. Fremont. Bulletin de la Société d'Encouragement pour l'Industrie nationale, vol. 120, no. 3, Mar. 1921, pp. 241–253, 22 figs. Experimental study of relation between behavior of steel plate in stamping press and mechanical properties. Steel plates were principally tested, also copper, brass and aluminum plates.

STANDARDIZATION

Austria. History and Activity of the Austrian Committee on Standards for Trade and Industry (ÖNIG) (Geschichte und Tätigkeit des österreichischen Normenausschusses fur Industrie und Gewerbe), P. Bretschneider. Zeit. des Oesterr. Ingenieur-u. Architekten-Vereines, vol. 73, no. 13, Apr. 1, 1921, pp. 81–82. (Abstract.)

STAYBOLTS

Standardization of. Standardization of Boiler and Staybolt Taps. Ry. Jl., vol. 27, no. 4, April 1921, pp. 12–17, 7 figs. Suggestions and recommendations made by Committee of Am. Ry. Tool Foremen's Assn.

STEAM-ELECTRIC PLANTS

Chicago. The New Gulbransen-Dickinson Plant. Power Plant Eng., vol. 25, no. 8, April 15, 1921, pp. 401–405, 5 figs. Wood waste utilized as fuel in steam electric isolated plant of Chicago Player Piano Manufacturer.

Newcastle-on-Tyne. A Modern Power Station and Its Development, J. S. Watson. Trans. North-East Coast Instn. Engrs. & Shipbuilders, vol. 36, part 8, Oct. 1920, pp. 496–506 and (discussion) pp. 506–538, 2 figs. on supp. plate. Steam-electric station at Newcastle-on-Tyne with total capacity of 186,540 kw.

STEAM ENGINES

Governors. The "Bee" Governor. Practical Engr., vol. 63, no. 1775, Mar. 3, 1921, pp. 139–142, 5 figs. Patented direct-acting spring-loaded enclosed governor.

The Regulation of Slow-Speed Steam Engines by Means of Slipping Eccentrics (Regeling van een stoomwerktuig met verstelbaar excentriek bij een laag aantal omwentelingen), G. Brouwer. Ingenieur, vol. 36, no. 7, Feb. 12, 1921, pp. 126–131, 8 figs. It is shown that centrifugal governors are not adapatable to slow-speed engines, and an oil-pressure governor without centrifugal action is described which is said to be adaptable for such engines.

Rolling-Mill Drive. A Big Vertical Mill Engine. Engr., vol. 131, no. 3405, April 1, 1921, pp. 354–355, 9 figs. partly on 2 supp. plates. Three-cylinder rolling-mill engine capable of developing maximum of 25,000 hp. at 140 r.p.m. Cylinders are each 45 in. diameter by 42 in. stroke and all take steam at 190 lb. per sq. in., superheated 100 deg. fahr.

STEAM POWER PLANTS

Layout. Fundamental Principles for the Constructional Arrangement and Develpment of Power Plants (Grundzüge fur die bauliche Anordnung und Entwicklung von Kraftwerksanlagen), A. Rüster. Zeit. des Bayerischen Revisions-Vereins, vol. 25, nos. 4 and 5, Feb. 28 and Mar. 15, 1921, pp. 25–28 and 33–35, 8 figs. Deals with plants for generation of heat. Details of steam-boiler installations of modern power plants. (Abstract.)

STEAM TURBINES

Installation. New Turbine Plant of the Hudson Motor Car Co. Power, vol. 53, no. 15, April 12, 1921, pp. 572–575, 8 figs. Turbines of condensing and non-condensing types installed with flexible arrangement to supply varying quantities of exhaust steam.

[See also MARINE STEAM TURBINES]

STEEL

Alloy. See ALLOY STEELS.

Chromium. See CHROMIUM STEEL.

Copper, Influence of. Influence of Copper on Some Physical Properties of Iron and Steel, E. A. Richardson and L. T. Richardson. Chem. & Metallurgical Eng., vol. 24, no. 13, Mar. 30, 1921, pp. 565–567. Number of ferrous alloys were made and physical properties of forging, filing, grinding, chiseling and bending determined. It was found that copper caused iron to be red-short and that manganese or chromium removed this difficulty.

Corrosion-Resisting. Anomalies Encountered in a Study of Immersion Tests of Iron and Steel, Allerton S. Cushman and George W. Coggeshall. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 22, pp. 249–267, 3 figs. Plea for considering all possible factors when comparing corrosion tests of iron and steel, on ground that there are in reality so many and so obscure variables that it is very easy to draw wrong conclusions. Tests in aluminum sulphate solutions, giving curious colloidal gels, are described. Writer denies protective action of copper in steel.

Observations on the Corrosion of Iron and Steel, J. A. Aupperle and D. M. Strickland. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 17, pp. 167–177, 2 figs. Records of tests on pure iron made in open-hearth furnaces, copper iron, plain steel and copper steel, to determine their resistance to sulphuric acid corrosion. Specimen sheets were tested 60 days in each case, either alone or fastened to sheets of pure iron by copper rivets or iron rivets, forming galvanic couples.

The Gap Between Theory and Practice in the Production of Corrosion-Resisting Iron and Steel, William D. Richardson. Thirty-Ninth Gen. Meeting, Am. Electrochemical Soc., April 21–23, 1921, advance paper no. 16, pp. 147–165. Electrolytic theory of corrosion is discussed, also influence of oxygen and role of adhering rust. Accelerated corrosion tests are studied, and their defects pointed out. Behavior of copper-bearing iron, silicon-containing cast-iron, nickel and nickel-chromium steels, nickel-copper steels, chromium steels, and nickel-cobalt-chromium alloys is investigated.

Magnet. See MAGNETS, Steel for.

Metallography. The Metallography of Low Carbon Steel, James Mitchell. Jl. West of Scotland Iron & Steel Inst., vol. 28, part 4, Jan. 1921, pp. 38–45 and (discussion) pp. 45–49, 27 figs. on 4 supp. plates. Interpretation of photomicrographs.

Structural. See STRUCTURAL Steel.

Testing. The Testing of Steel, D. Sillars. Foundry Trade Jl., vol. 23, no. 240, Mar. 24, 1921, pp. 268–270. Comparative value of tests ordinarily applied.

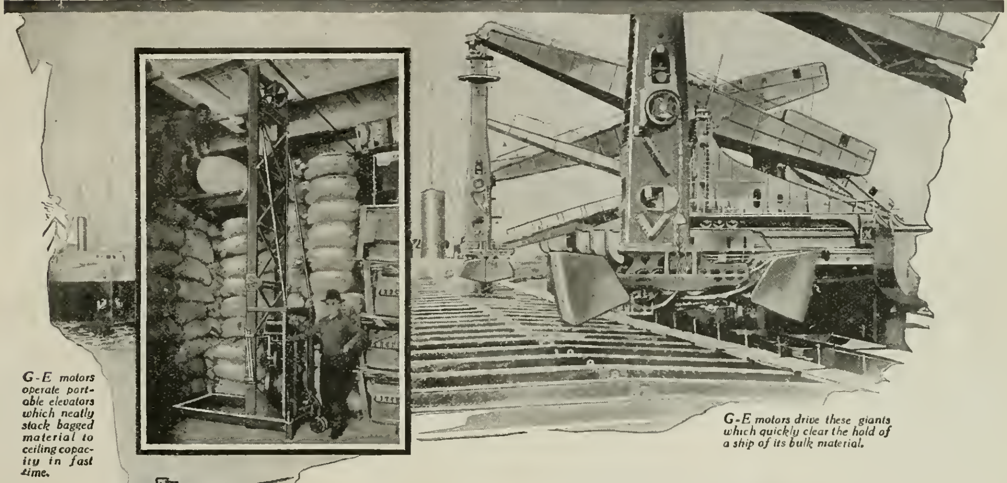
Tests. Experimental Investigations of the Behavior of Wrought Iron and Low-Carbon Steel at Freezing Temperature under Sudden Stress (Versuche über das Verhalten von Schweisseisen und Flusseisen in der Kälte bei plötzlicher Beanspruchung), Ed. Wilh. Kaiser. Stahl u. Eisen, vol. 41, no. 10, Mar. 10, 1921, pp. 333–337, 8 figs. Under sudden stress influence of freezing temperature on both wrought iron and low-carbon steel is considerable. With cooling off to 20 deg. cent., low-carbon steel loses about 85.5 per cent, wrought iron only 42.3 per cent.

STEEL CASTINGS

Centrifugal Process. Tests of Centrifugally Cast Steel, George K. Burgess. Trans. Am. Soc. for Steel Treating, vol. 1, no. 7, April 1921, pp. 370–382, 26 figs. Photomicrographic examination of castings made by Millsbaugh centrifugal processes.

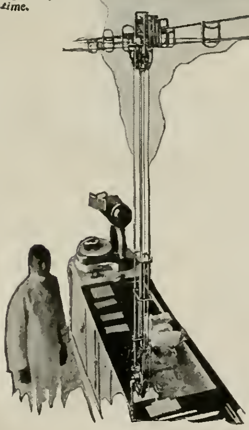
Tests of Centrifugally Cast Steel, George K. Burgess. Iron Age, vol. 107, no. 12, Mar. 24, 1921, pp. 764–766, 5 figs. Results suggested possibility that centrifugally cast steel suitably treated may rival properties of forgings of same chemical composition.

Whether material must be handled by mechanical giants or midgets, electric motors perform the work unfailingly



G-E motors operate portable elevators which neatly stack bagged material to ceiling capacity in fast time.

G-E motors drive these giants which quickly clear the hold of a ship of its bulk material.



Your change in a hurry—the G-E motor way of handling cash in the big stores.

Tons or ounces—

G-E MOTORS drive huge buckets into the hold of a ship and unload it like magic. They drive tireless mechanical devices which do the weary work of stacking and re-stacking goods in a warehouse or stockroom. They drive all manner of appliances which save countless steps in many fields of labor.

With each new application of G-E motors to material-handling problems, costs find a lower level and production leaps forward.

The work of days to men becomes that of minutes when the power of G-E motors is put to the wheel. And their scope is boundless.

Wherever material is to be moved, G-E motors are applicable, for there is one for every job—from the mightiest to the tiniest.

The leading manufacturers of material-handling machinery are prepared to supply devices equipped with G-E motors and control.

ENGINEERING INDEX (Continued)

STEEL, HEAT TREATMENT OF

Cooling, Effect of. Effect of the Rate of Cooling on the Magnetic and Other Properties of an Annealed Eutectoid Carbon Steel, C. Nus baum and W. L. Cheney. U. S. Dept. of Commerce, Sci. Papers of Bur. of Standards, no. 408, Jan. 22, 1921, pp. 65–78, 11 figs. Specimens of steel were heated to 800 deg. cent. and allowed to cool at various rates, one in air, one in lime and others in furnace at slower and slower rates. It was found that as cooling rate is diminished there is pronounced increase in value of maximum induction for given small magnetizing force, decided increase in maximum permeability, but decrease in coercive force.

Chrome-Nickel Steel. Notes from the Workshops of a Refined Steel Foundry (Einiges aus der Werkstätte des Edelstahlwerkers), Erdmann Kortny. Stahl u. Eisen, vol. 41, no. 7, Feb. 17, 1921, pp. 213–223, 4 figs. In order to determine the correct heat treatment of chrome-nickel steel which is also used as construction steel for overhung crankshafts, forgings tests were carried out with rolled material at different temperatures, results of which are given in tabular form. Instructions are given for the production of overhung shafts and crankshafts for the different departments of a refined steel works. See same Jl. Jan. 8 and May 20, 1920.

STEEL MANUFACTURE

Direct Process. Direct Process of Manufacture of Iron and Steel from the Ore (La fabrication directe du fer et de l'acier à partir du minerai). Métallurgie, vol. 53, no. 8, Feb. 23, 1921, pp. 385–386. Chaplet-Arnou process. (To be continued.)

STEEL MILLS

See ELECTRIC DRIVE, Steel Mills.

STRESSES

Blocks, Distribution in. Contact Pressures and Stresses, E. G. Coker, K. C. Chakko and M. S. Ahmed. Engineering, vol. 111, no. 2883, April 1, 1921, pp. 387–389, 4 figs. Stress distribution in blocks of equal breadth and depth when subjected to load over part of one edge and supported over opposite edge. (Continuation of serial.)

STRUCTURAL STEEL

Standards. Reports of the Permanent Committee of Standardization (Rapports de la commission permanente de standardisation). Mémoires et Compte rendu des Travaux de la Société des Ingenieurs Civils de France, vol. 73, nos. 10, 11 and 12, Oct.-Dec. 1920, pp. 660–718, 2 figs. Standards for and methods of testing structural steel.

SUBMARINES

German, Engine Clutches. Main Engine Clutches for German Submarines, M. C. Bowman. Mech. Eng., vol. 43, no. 4, April 1921, pp. 278–279, 4 figs. Clutch is of double-cone friction type of semi-steel and cast iron and is operated by air except in 530-hp. size which is operated by hand through worm and gear.

SUGAR MACHINERY

Construction. Construction and Repair of Sugar Machinery, Frank A. Stanley. Am. Mach., vol. 54, no. 16, April 21, 1921, pp. 677–682, 20 figs. How huge rolls and other parts are made and conveyed to mill. Loam-mold and core making. Making tools.

SUPERHEATERS

Foster Double-Stage. Foster Patent Double-Stage Superheater. Shipbuilding & Shipping Rec., vol. 17, no. 10, Mar. 10, 1921, pp. 285–286, 3 figs. Combined flue type and smoke-tube type, giving high-superheated steam to marine engines and low-superheated steam to auxiliaries.

T

TAPS

Standard. Screw Taps for Whitworth Thread with Clearance at Top (Gewindebohrer für Whitworth-Gewinde mit Spitzenspiel), J. Reindl. Betrieb, vol. 3, no. 10, Feb. 25, 1921, pp. 257–259, 6 figs. Discussion of the relative merits of two forms of screw taps, based on approved standards for Whitworth thread with top clearance of the German Industry Committee on Standards (N D I).

TERMINALS, LOCOMOTIVE

Design. Modern Engine Terminals and Repair Shops, H. E. Stitt. Official Proc. Central Ry. Club, vol. 29, no. 2, Mar. 1921, pp. 1010–1022, 12 figs, also in Ry. Age, vol. 70, no. 13, Apr. 1, 1921, pp. 829–832, 4 figs. Successful operation of railway terminals by proper design of terminal buildings. Typical designs of locomotive terminals.

Location and Distribution of the Central-Station Power of the Middle West

By W. L. Abbott,[1] Chicago, Ill.

The location and distribution of the central-station power of the Middle West is a subject which has neither the large commercial possibilities of the proposed superpower system of the North Atlantic states nor the spectacular engineering interest of the hydro developments of the Pacific states. The power development of the low, level, rich prairie country, with its wealth of cheap coal, is peculiar to itself, and the distribution is working out its destiny following its natural instincts.

Fig. 1, taken from a recent issue of the *Electrical World*, is an ingenious redistribution of the area of the country, designed to show up the various states in their true electrical importance. This map, which represents relative kilowatt-hour production, is doubtless a fairly accurate representation of installed kilowatt capacity, the total for the United States being given as 12,600,000, of which about one-third, or 4,000,000 kw., is hydroelectric.

Location of the Water Powers of the Middle West

The various potential power streams of the country and the water powers are generally located where they will do the most good—that is, remote from coal mines—the Middle West, in comparison with the rest of the country, not being particularly favored. The states of Ohio, Indiana and Illinois, which are richest in coal, are poorest in water power. Only 18 per cent, or 776,000 kw., of the water power of the country lies in the middle-western states, and the greater part of this is in the states of Michigan, Wisconsin, and Minnesota. Portions of Ohio rise 500 ft. above the Ohio River and above Lake Erie, but the whole state is credited with only 40,000 kw. installed central-station hydroelectric power.

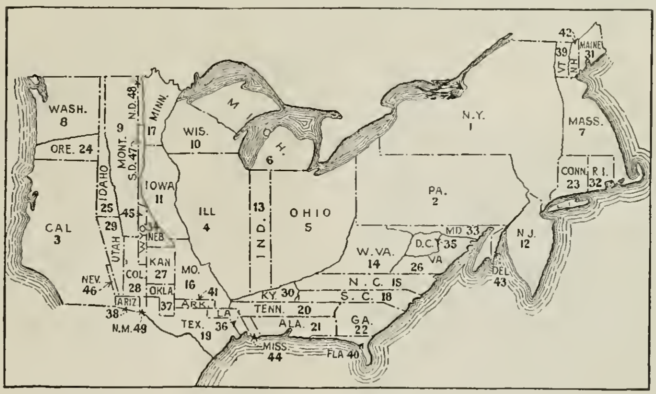

Fig. 1 Relative Sizes of States Based on Their Kilowatt-Hour Production

In Southern Michigan and Northern Indiana is a land elevation of more than 500 ft. above Lake Michigan, giving the St. Joseph River and its tributaries a fall of 10 ft. to the mile over its entire length. The effect of this fall is to dot the map with water powers all along the river's course. A similar elevation near Detroit has its effect on the Huron River, and a hogback up through the center of the southern peninsula makes good mill streams of the Au Sable River, of the Manistee, Grand and Muskegon.

Along the southern shore of Lake Superior the land elevation is, in places, 1000 ft. above the lake, but the territory drained is rather restricted and the rivers are so short that the streams are torrential for a brief interval and almost dry much of the time.

The lower Fox River, between Lake Winnebago and Green Bay, Wis., has a drop of 170 ft. in 28 miles, along which over 40,000 kw. of power was installed long ago and fully occupied by local industries. The level plateau of the watershed of the Fox River and the large pondage of Lake Winnebago make the lower Fox River an ideal one for power. The principal discharge for the rivers of Central Wisconsin is the Mississippi River, which is about 700 ft. above sea level, and as the center of the state abounds in lakes and marshes at elevations of 500 to 1000 ft. above the mouths of the rivers which drain this interior, many important water powers are being developed on these rivers, as at Kilbourn, 6000 kw.; Prairie du Sac, 18,000 kw.; Eau Claire and vicinity, 50,000 kw.; and St. Croix Falls, 18,000 kw.

The principal central-station water power of Minnesota is 50,000 kw. in the vicinity of Duluth. The great water power of the Mississippi River that made Minneapolis famous is principally taken up by flour mills and other local industries. About 33,000 kw. of this power is classified as central-station power.

The territory comprised in this survey includes and extends from Western Pennsylvania to Eastern Kansas, from Southern Kentucky to the Great Lakes and the Canadian border. It comprises an area of 660-000 square miles and a population of 40,000-000. It all lies in the Mississippi Valley and scarcely one per cent can be rated as mountainous, its broad stretches of prairie and forest lands having in general such slight declivity and absorbent soil that the water run-off, excepting that lost in floods, does not exceed one-fifth of the precipitation, and its placid streams for the greater part of their courses flow to the lakes or sea with a slope of half a foot to the mile.

Such a gentle fall of course makes possible relatively little water power, considering the length and breadth of the streams, but as compensation, because these streams have not eroded the soil, the prairie states, with their unrivaled fertility, will some day support a teeming population of hundreds of millions, whose increasing clamor for power must be satisfied principally, as now, by coal drawn from their own great stores.

Water power must be developed at the waterfall, and until long-distance transmission was developed that power had to be used where it was generated; and because much of such power was located in rough, inaccessible country, having no other features of com-

[1] Chief Operating Engineer, Commonwealth Edison Company. Mem. Am.Soc.M.E.

Presented at the Spring Meeting, Chicago, Ill., May 23 to 26, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

mercial importance, such rivers were allowed to roll on in solitude "and hear no sound save their own dashing." Now electric transmission has changed all of this, and whereas once factories went to the power, now power goes to the factories, and with a widening effective range of transmission lines and higher cost of coal, more and more of these wild waters are being broken to harness and few of those remaining are escaping serious consideration.

The Question of Power Plants at Mine Mouth

The example of hydroelectric power transmission naturally suggests that coal be burned at the mine to develop steam-electric power for transmission to remote markets, thereby saving the expense and uncertainties of rail shipment. The argument seems plausible, and yet the author is not aware that such a thing is being done anywhere in a large way. Indeed, it is doubtful if in any but the most favorable cases power plants at the mine mouth with a transmission line can successfully compete with power plants located in the remote centers where the power is to be used, the coal necessary for these plants being shipped by rail.

It must be admitted that during the past few years the railroads have done much toward popularizing electric transmission, but rates have not quite reached the point where, even under most favorable conditions in the Middle West, a power company would be warranted in maintaining a power plant at the mine, a stand-by plant in the city, and a transmission line between. Conditions, moreover, are seldom "most favorable," as with us the large quantity of flowing water necessary for condensing in a plant of upward of 50,000 kw. is seldom found at the mines. This renders it necessary to ship the coal to a power house located on a nearby river and to transmit electrically from there to the place where the power is to be used, but right here the railroads that have tried so hard to popularize all-electric transmission have unwittingly intervened with an awkward freight-schedule system, which renders a part rail and part line transmission impossible. This has happened because they did not know there was any system to their schedules, and while the author cannot say that these schedules were prepared according to any rule, he has nevertheless found a key that will fit the average of several taken at random. This key indicates that a coal freight schedule is composed of a basic charge of $1.00 a ton and a hauling charge of four-tenths of a cent per ton-mile. Let us see how this affects a rail and line transmission.

From the Springfield coal district to Chicago is 192 miles. This distance, at 0.4 cent per ton-mile, amounts to 77 cents; adding the basic $1.00 makes $1.77. The actual rate, $1.83, is a little less than 1 cent per ton-mile.

Fig. 2 Central-Station Power Distribution of the Middle-Western States

1—Chicago, Ill.	6—Windsor, W. Va.	11—Indianapolis, Ind.	16—Duluth, Minn.
2—Cleveland, Ohio	7—Keokuk, Iowa	12—Columbus, Ohio	17—Joplin, Mo.
3—St. Louis, Mo.	8—Cincinnati, Ohio	13—Toledo, Ohio	18—Akron, Ohio
4—Detroit, Mich.	9—St. Paul, Minn.	14—Kansas City, Mo.	19—Moline, Ill.
5—Pittsburgh, Pa.	10—Milwaukee, Wis.	15—Louisville, Ky.	20—Cabin Creek Jct., W. Va.

There being no dependable supply of condensing water near Springfield, it has been suggested that the coal destined for Chicago power be shipped to Peoria, where there is water in abundance, used there in power houses, and the electric energy sent to Chicago via a high-tension line.

From Springfield to Peoria is 62 miles, which at 0.4 cent is 25 cents; adding the basic $1.00 gives $1.25. The actual rate is $1.17, —a little less than 2 cents per ton-mile, or about double the ton-mile rate from Springfield to Chicago.

Obviously, the Springfield-Chicago all-rail shipments need have no fear of competition via the Springfield-Peoria-Chicago rail and line route.

Location of Power Stations and Distribution Lines in the Mid-West Territory

Fig. 2 is a map showing the distribution lines of the territory discussed and also showing by dots and circles the centers where the power is generated and used. The smallest circle shown represents 500 kw.; smaller amounts of power are indicated by dots. Central power stations of less than 500 kw. and not connected up to another center do not appear on the map. Broken circles indicate a power station, the greater part of whose output is included in the area of some solid circle. The developed central-station power of the Middle West is 4,500,000 kw., of which all but 18 per cent is from steam power.

The large circle, indicating 500,000 kw. for the central stations of Chicago and vicinity, is the dominating feature; following in order are Cleveland, St. Louis and Detroit, each with a little more than 200,000 kw. The 210,000 kw. of St. Louis is made up in part by its own Ashley Street Station and in part by the 100-000 kw. from the Keokuk dam, shown as circle 7. One significant feature of the important high-voltage transmission lines indicated in the figure is that such lines are used almost entirely to connect water powers with centers where their power is used, the exception to this being in the vicinity of Pittsburgh, where mine-pit cars dump their coal into the hoppers of boiler rooms located on river banks, and in Detroit, where a small amount of power is distributed at 46,000 volts; also a short 66,000-volt line owned by the Doherty interests in Central Ohio.

The line over which the greatest amount of power is transmitted connects the Stone & Webster Keokuk power with St. Louis at 110,000 volts. Probably the system next in importance is that of Hodenpyl & Hardy in Michigan, connecting up water powers on the Au Sable, Manistee and Grand with a line of 140,000 volts—

The Hardness Testing of Metals[1]

Report of a Committee of the Engineering Division of the National Research Council on Various Methods of Testing the Hardness of Metals

THE Committee on A New Hardness-Testing Machine of the Engineering Division of the National Research Council was formed at the suggestion of Dr. Henry M. Howe to obtain, if possible, more satisfactory methods of measuring the hardness of metals. The following reports were submitted to the committee in the course of its work and are published here as it is believed that they will assist others interested in hardness measurements.

Brinell Tests with Etched Ball[2]

This method, devised by Axel Hultgren, is used on hardened steel in order to obtain indentations which are easier to read than those produced with polished balls. Either 5-mm. or 10-mm. steel balls may be used. The balls are wiped free from grease and thoroughly cleaned in alcohol, and thereafter etched for 2 to 4 minutes under agitation in a solution of 1 per cent nitric acid in alcohol and cleaned again in alcohol. The hardened steel surface to be tested is ground and polished as usual, the higher the polish the better. The load—1000 kg. or 750 kg. for 5-mm. ball, 3000 kg. for 10-mm. ball—is applied as usual in a Brinell testing machine.

In reading the indentation with a Brinell microscope the light should fall at a steep angle. If polishing scratches running in one direction are left on the surface of the specimen, the light should fall in the same direction in order that the best definition of the indentation circle may be obtained. Under the conditions described, the diameter can be read with greater sharpness and more ease than when a polished ball has been used, due to the contrast between the dull indentation surface produced by the etched ball and the surrounding surface.

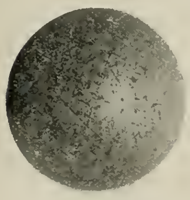

Fig. 1 Appearance of the Brinell Ball after the Polish Has Been Removed by 1 Minute's Immersion in 1 Per Cent Alcoholic Solution of Nitric Acid

The dullness is explained as follows: The ball being made of a hypereutectoid steel, the etched surface presents numerous small cementite grains standing out in relief from the matrix, which is martensite. When this surface is pressed against the surface of the specimen so as to produce an indentation, numerous small holes are formed in the latter by the cementite grains in the former. The dull appearance of the indentation is an effect of these small holes.

In order to show the advantage of using the etched ball in making Brinell hardness determinations, H. S. Rawdon of the Bureau of Standards was requested to illustrate the results photographically. He has done this and given, in addition, the discussion which follows:

To test the method a portion of a file from which the teeth had been entirely removed was used. This was highly polished as for microscopic examination. The balls were 10 mm. in diameter and indentations were obtained with a load of 1000 kg. applied for 30 seconds. The balls were etched in a 1 per cent alcoholic solution of nitric acid for two minutes.

Fig. 1 shows the appearance of one of the balls after etching. The surface pattern revealed, which resembles that of the dendritic structure of steel, may be the result of abrasion markings, caused by the grinding of the balls, which subsequently were hidden but not entirely removed by the polishing of the balls. A microscopic examination of the surface of the ball after etching reveals the structure of the material. The steel consists of innumerable particles of carbide embedded in a matrix which is probably somewhat softer than the carbide. The matrix etches more readily than the carbide so that the tiny particles of carbide stand in relief over

Prof. H. F. Moore, University of Illinois, Urbana, Ill.
Prof. John H. Nelson, Wyman & Gordon Company, Worcester, Mass.
P. M. Taft, Illinois Watch Company, Springfield, Ill.
The American Society of Mechanical Engineers has donated a bibliography on hardness, copies of which can be obtained from the chairman.

[2] From report prepared by Axel Hultgren, Svenska Kullagerfabriken, Gothenburg, Sweden.

the surface of the ball. The diameter of the ball is not reduced to any appreciable amount, as the specimen is etched only to about the same degree as is the usual practice for revealing the microstructure.

The indentation produced by the etched ball has a "matt" appearance and is readily visible when the specimen is viewed at almost any angle. The impression produced by the unetched ball is almost invisible when the light strikes the surface at certain angles, and particularly is this so when the line of vision is approximately normal to the surface.

Figs. 2 and 3 show the appearance of the spherical surface of

Fig. 4 Brinell Indentation on Hard Steel with Unetched Ball. Magnification × 50

an indentation obtained with the etched ball, viewed with "vertical illumination," that is, normal to the surface. It is readily seen that the matt finish is due to numerous tiny pits, caused undoubtedly by the projecting carbide particles on the surface of the etched ball. The indentation consists of two zones. In the inner one the pits are larger and more numerous than in the outer one and are often slightly elongated and arranged in concentric rings. This is caused by a slight rotary motion of the ball as the pressure is applied. The pits in the outer zone are much smaller, the line of demarcation between the two being very sharp. Fig. 3 shows the difference between the two zones of the indentation more clearly. The micrograph (×100) covers only one quadrant of the impression. Evidently the pressure applied to the ball is not transmitted equally to all parts of the metal covered by the indentation. Fig. 4 shows a view (×50) of an impression obtained with an unetched ball; the dark area is an ink spot which was placed at the center of the indentation in order to locate it. Only very slight traces of the impression can be seen, though a few pits similar to these noted in the other type of indentation may be noted. There is nothing, however, to mark the outer limit of circumference of the indentation.

If desired, an area on the surface of the specimen to be tested may be etched with alcoholic nitric acid before the indentation is made. In this case it is not necessary to etch the ball. The impressions obtained in this way are considerably more conspicuous than those obtained with an unetched ball on a polished specimen, but not quite so conspicuous as those produced by the etched ball on a polished surface.

A further advantage in the use of etched balls may be mentioned. After the indentation has been made, a bright spot remains on that side of the ball which was in contact with the material tested. This renders it an easy matter to turn the ball so that an unused, and therefore a much less distorted, portion of the ball can be employed for a subsequent hardness determination.

Impact Hardness Apparatus

One of the problems of hardness testing has been the determination of the hardness of the large masses of metal which could not be moved readily, and especially the hardness of surfaces which were vertical or in such a position that the use of the scleroscope or Brinell machine was impossible.

Impact Brinell machines in which the impact of a hand hammer is used have been devised. The blow causes a ball between the material to be tested and a material of known hardness to indent both. The hardness desired is computed from the impressions in the two materials. Two instruments of this type, the Morin apparatus and the Brinell meter, have been tested.

Morin Hardness-Testing Apparatus[1]

Description of the Apparatus. The Morin hardness-testing apparatus, Figs. 5 and 6, was tested to ascertain its practical value in determining the hardness of metals. It consists of a cylindrical case in which a steel ball, a standard cube, and a plunger are held firmly in contact in their proper relative positions by a coil spring which surrounds the plunger.

The ball, 10 mm. in diameter, projects slightly from one end of the case so that it may be brought into contact with the specimen. The plunger, projecting about one-half inch from the other end of the case, may be struck by a hammer. The standard cubes are about ½ inch in each dimension. A dozen cubes having different hardnesses are supplied by the maker. The case is so designed that the cubes may be readily put in place, or removed, without having the ball or plunger leave their places.

To make a hardness determination the standard cube is selected that has about the same hardness as the specimen. It is placed in the case, the latter held perpendicularly to the surface of the specimen and the plunger struck with a hammer (see Fig. 5). The ball, held between the standard cube and the surface, indents both of them. The diameter of the impression in the standard cube is measured, as well as that in the specimen. Knowing the two diameters and the Brinell hardness of the cube which has been determined in the usual way, a special circular slide rule provided with the instrument and shown in Fig. 6 is used to determine the hardness of the specimen.

Outline of Tests. For testing the apparatus, carbon steels were used having Brinell hardness numbers ranging from 88 to 302. Standard cubes similar to those supplied with the apparatus were prepared from the same piece of steel. Three series of tests were

Fig. 5 Morin Hardness-Testing Apparatus Ready for Use

made to determine the influence of various factors upon the hardness numeral as given by the instrument: namely,

1 The influence of variations in the energy of impact where the standard cubes and specimen are the same
2 The influence of variations in the hardness of the standard cubes where the hardness of the specimen is constant
3 The influence of variations in the hardness of the material when the hardness of the standard cube is constant.

[1] This report (Bureau of Standards Lab. No. 1118a20) was prepared by H. L. Whittemore, S. N. Petrenko, and L. B. Tuckerman.

In all the tests except Nos. 27 to 35 the blow was given by a 10-lb. sledge hammer. A pin through the handle at a distance of 3 ft. from the hammer head served as an axle. The hammer was raised the required height and then released. When dropped under the influence of gravity the hammer head struck the apparatus resting on the specimen. In tests Nos. 27 to 35 the blow was given by a hand hammer weighing 1 lb.

Fig. 6 Parts of the Morin Hardness-Testino Apparatus in Their Proper Relative Positions

Results of Tests. The results of the various series of tests are given in Table 1. In the last column on the table are given Morin-Brinell hardness numerals as determined by means of the slide rule provided with the apparatus. As a check on the Brinell hardness numbers, the scleroscope hardness of the standard cubes and of the specimens is given in the tables. The Brinell hardness was determined by an Alpha Brinell machine, using a 10-mm. ball and a load of 3000 kg.

In the tests of Series 1, two widely different amounts of impact energy were used. The hammer was dropped from the heights of 3 in. and 6 in., the corresponding energies of impact being 30 in-lb. and 60 in-lb., respectively. A comparison of the values in the last column of the table shows that the energy of impact has no apparent influence upon the results.

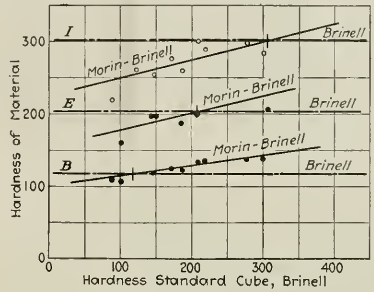

Fig. 7 Graphs of Results of Tests of Series 2; Energy of Impact, 60 in-lb.

In studying these results it should be remembered that the standard cubes and the specimens were of the same material. The slight differences in their Brinell hardnesses is due to variation in hardness of the material and to the usual errors in the determination of the hardness. The results are therefore in this respect obtained under unusually favorable conditions. On the other hand, the hardness of the test pieces was not uniform and the differences in Morin-Brinell hardness and Brinell hardness possibly were partly due to the actual differences of hardness in various parts of the test pieces. The maximum error for the 60 in-lb. impact is 15.2 per cent and the average 5.9 per cent. For the 30 in-lb. impact the maximum error is 20.2 per cent and the average 8.3 per cent.

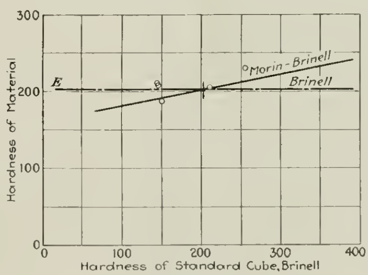

Fig. 8 Graph of Results of Tests of Series 2; Energy of Impact, 20-30 in-lb.

The difference between the Brinell hardness of the material as determined in a Brinell hardness machine and the Morin-Brinell hardness is probably not due to the energy of impact being too great or too small, but to the errors of the apparatus itself and to the variations in the hardness of the test pieces and of the standard cubes. However, it may be said that the 60 in-lb. impact gives the more consistent results. It is also to be noted that the irregularities of the readings increase with increasing hardness, perhaps due in part to the difficulty in accurately measuring the small impression.

In tests Nos. 3 to 20, Series 2, the hardest (Brinell hardness 302) as well as one of the softest (Brinell hardness 119) materials were chosen and tested with standard cubes of various degrees of hardness. The results are shown graphically in Figs. 7 and 8. In these graphs the constant Brinell hardness of the specimen is shown by the horizontal line marked "Brinell." The hardness values of

the specimen as found by the Morin apparatus are plotted as ordinates, using as abscissas the Brinell hardness of the standard cube. If results are desired which are accurate within 10 per cent it is apparent from the graphs that the hardness of the standard cube should not differ from that of the specimen by more than 100 Brinell numbers. Due to the fact that many of the Morin-Brinell values do not lie close to the plotted line among the points, it seems reasonable to reduce this difference one-half, or to 50 Brinell numbers.

In Series 3, tests Nos. 32 to 35, specimens of various hardnesses were tested with standard cubes of constant hardness (150). The results of these tests confirm the deduction from the previous tests as shown in Fig. 9.

Conclusions. From a study of the results obtained in the various series of tests the following conclusions have been arrived at:

1 The hardness obtained with a Morin hardness tester is not affected, to any considerable degree, by the amount of energy of impact. Too light a blow is likely to give more erratic results than a heavy blow, and as the correct measurement of the diameter of a small indentation is difficult, the diameter of the impression should not be smaller than 2.5 mm. or possibly 3 mm.

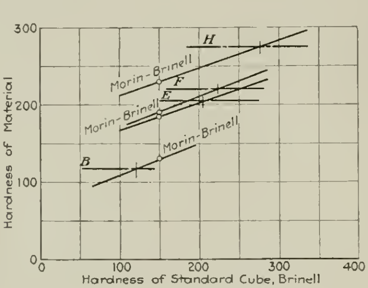

FIG. 9 GRAPH OF RESULTS OF TESTS OF SERIES 3; ENERGY OF IMPACT, 20-30 IN-LB.

2 The hardness of the standard cube should be as near that of the specimen as possible. A difference in hardness amounting to more than 50 Brinell units would be likely to make the error exceed 10 per cent. It is possible that this limitation might be removed by the use of an appropriate correction formula, but this would still further complicate the use of the apparatus.

3 The standard cubes should be uniform in hardness and their Brinell hardness should be determined before they are cut out of a bar, as any error appears in the hardness of the test piece.

4 The size of the standard cubes is too small to obtain their Brinell hardness accurately. They are distorted by the 3000-kg. load more than would be the case with larger blocks.

5 Due to the fact that each block can be used for only six readings, the time and expense required to make additional blocks is a rather serious restriction on the use of the apparatus.

6 The proximity of the hardness of the standard cube to that of the specimen to be tested is numerically of greater importance in the case of hard material than in the case of soft, as shown by the slope of the curve in Fig. 7.

THE BRINELL METER[1]

Description of the Apparatus. The Brinell Meter apparatus consisted of a cylindrical case which held the parts in their proper relative position. At one end was a 10-mm. steel ball, next a standard bar, then a plunger. These were held in contact by a coil spring which surrounded the plunger. A cap which screwed into the end of the cylinder held the parts in place. The steel ball projected from one end of the case so that it could be brought into contact with the specimen whose hardness was desired. The standard bar, approximately, ½ in. square in cross-section by 6 in. long, could be placed in position between the ball and the plunger through holes in the side of the case. The Brinell hardness number was stamped on the bar. Fig. 10 shows the apparatus ready for use and Fig. 11 the parts in approximately their relative positions.

[1] This report, Bureau of Standards Lab. No. 1231a20 (No. 17–203 revised), prepared by H. L. Whittemore and L. B. Tuckerman, includes experimental data on the Brinell Meter obtained by T. L. Sorey.

In order to determine the hardness of a specimen, a standard bar having nearly the same hardness is placed in the apparatus so that the ball rests on an unindented portion. The apparatus, held in the hand, is placed so that the ball rests on the specimen. The plunger is then struck by a 3-lb. hand hammer.

The diameter of the indentation in the standard bar is divided by the diameter of the indentation in the specimen and special tables supplied with the instrument are used to obtain the Brinell Meter hardness of the latter. For measuring the diameters of the indentation, transparent sheet celluloid scales were provided. One of these scales had two lines about 8 cm. long, 5 mm. apart at one end and 3 mm. at the other. The lines were graduated so that one division equaled a change in distance between the lines of 1/20 mm. On the other scale the lines were respectively, 3.5 mm. and 1.5 mm. apart at the ends.

Theory of Brinell Hardness. The Brinell hardness numeral (B. h.n.) was originally defined as the ratio of the load on a sphere, used to indent the specimen, to the area of the spherical indentation produced. The hardness is calculated by the formula—

$$H = \frac{P}{\pi t D}.$$

in which H is the Brinell hardness numeral, P the load on the sphere D the diameter of the sphere and t the depth of the indentation. This depth t was calculated from the observed diameter, d, of the indentation by the formula—

$$t = \frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}$$

Experiment has shown that the B.h.n. so defined varies with the load and diameter of the sphere. This is at least partially due to the elastic deformation of the sphere,[1] and it has therefore become standard practice to define the B.h.n. as the value obtained under a load of 3000 kg. with a ball of 10 mm. diameter. For soft metals a load of 3000 kg. is too great, and therefore 500 kg. has become standard practice.

Theory of the Brinell Meter. The hardness tables furnished with the Brinell Meter are evidently calculated from the formula—

$$\frac{H_1}{H} = \frac{d^2}{d_1^2}$$

in which H is the Brinell hardness of the specimen, H_1 the hardness of the standard bar, and d and d_1 are the diameters of the indentations. This is obtained as an approximation from the Brinell formula $H_1/H = t/t_1$ when the two impressions are obtained from the same load, and its use results in an extreme case in an error of about 2 per cent.

FIG. 10 BRINELL METER READY FOR USE

[1] Technologic Paper, Bureau of Standards, No. 11, entitled Five Methods of Measuring Hardness.

As the accuracy of the results obtained with this apparatus depends directly upon the hardness marked upon the standard bars their hardness was determined in an Alpha Brinell machine. The values are given in Table 2.

Outline of Tests. For convenience it was decided to test the Brinell Meter first under static loads. An Olsen testing machine was used to apply loads to the Brinell Meter resting upon a specimen. In this way the effect of different loads on the accuracy of the static hardness reading can be determined. The diameters of the impressions in both the specimens (d_1) and that in the standard bar (d) were measured with a micrometer microscope such as is supplied with an Alpha Brinell machine. The data are given in Table 3. The hardness of the specimen was calculated by the formula $H_1 = Hd^2/d_1^2$.

Since these results showed that so far as static loads were concerned the Brinell Meter could be relied upon within 2 per cent over a wide range of loads, the apparatus was then tested by hammer blows for which it was designed. The results of these tests are given in Table 4.

[1] Standard load.
[2] Not standard load.

Conclusions. I The dimensions of the standard bars are so small as to cause error in measuring their hardness in the usual manner. It would seem that a cross-section of at least twice the dimensions would be preferable.

2 A variation in the applied load causes a slight change in the hardness numeral, but Table 3 shows that in most cases for the static load tests the Brinell Meter hardness was practically identical with the Brinell hardness if the standard load of 3000 kg. was used. Both values decrease with decreasing loads, and the decrease in the Brinell hardness emphasizes the necessity for using the standard load of 3000 kg. for hard and a load of 500 kg. for soft metals.

3 The errors in the Brinell Meter hardness due to variations in load are less than for the Brinell hardness.

FIG. 11 PARTS OF THE BRINELL METER IN THEIR PROPER RELATIVE POSITIONS

4 The greatest accuracy is obtained when the diameter of the indentations for the Brinell Meter is approximately that obtained on the same material in a Brinell testing machine under standard load.

5 The celluloid scales should not be used to measure the diameter of the indentations. A micrometer microscope graduated to tenths of a millimeter, which division allows hundredths of a millimeter to be easily estimated, will be found suitable for the purpose.

Efficiency Tests of a 30,000-Kw. Steam Turbine

By HERBERT B. REYNOLDS,[1] NEW YORK, N. Y.

During 1920 three 30,000-kw. General Electric turbines were installed at the 59th Street power station of the Interborough Rapid Transit Company, New York City, complete tests upon one of which form the subject of the present paper.

These turbines are of the straight Curtis impulse type, having 20 pressure stages, each pressure stage consisting of one velocity stage. The normal steam pressure at the throttle is 225 lb. per sq. in., abs., the steam being superheated 150 deg. fahr., and exhausted into a vacuum of 29 in. Hg. The speed is 1500 r.p.m. Novel spring supports were provided for the condenser which are described in the paper.

The highest water rate obtained during the tests while operating under normal conditions was 11.03 lb. per kw-hr., while the highest Rankine-cycle and thermal efficiencies obtained were 75.5 per cent and 25 per cent, respectively. Results of tests on the condensers and auxiliaries are also given in the form of tables.

The results obtained in these tests of a large power-station unit form a welcome addition to the data of tests of turbines of the same capacity installed in 1915 at the 74th Street power station of the company, reported in a paper presented before the Society in 1916, by H. G. Stott and W. S. Finlay, Jr.

In order to provide additional power capacity for the new subways constructed in New York City during the period from 1913 to 1921, and operated by the Interborough Rapid Transit Company, additional turbine units were installed in both the 59th Street and 74th Street Power Stations. The three 30,000-kw. Westinghouse cross-compound turbines which were completed in 1915 were among the new units installed at the 74th Street Power Station. The results of the tests upon these three turbines were presented before the Society by H. G. Stott and W. S. Finlay, Jr., in 1916.[1]

At the 59th Street Power Station, the installation of three 30,000-kw. General Electric turbines has been completed within the past year. Very complete tests have been conducted upon these added units, the results of which are set forth on the following pages.

Reviewing briefly the history of the developments at the 59th Street Power Station, it will be recalled that the original engine-room equipment consisted of nine 7500-kw. maximum-capacity Manhattan type Allis-Chalmers double angle compound engine units, and three Westinghouse 1250-kw. turbines, the latter driving 60-cycle generators which supplied 60-cycle current for subway lighting. The use of this current for lighting was subsequently discontinued and in its place 25-cycle current is now used which is taken from the main units. During 1909 and 1910, five low-pressure 7500-kw. maximum-capacity General Electric turbine units were added, taking exhaust steam from five of the engines at atmospheric pressure. A description of these units and a full report of the tests which were conducted on them are given in a paper presented by H. G. Stott and R. J. S. Pigott before the Society in 1910.[2] The units most recently installed in the 59th Street Power Station are the three 30,000-kw. General Electric turbines mentioned above.

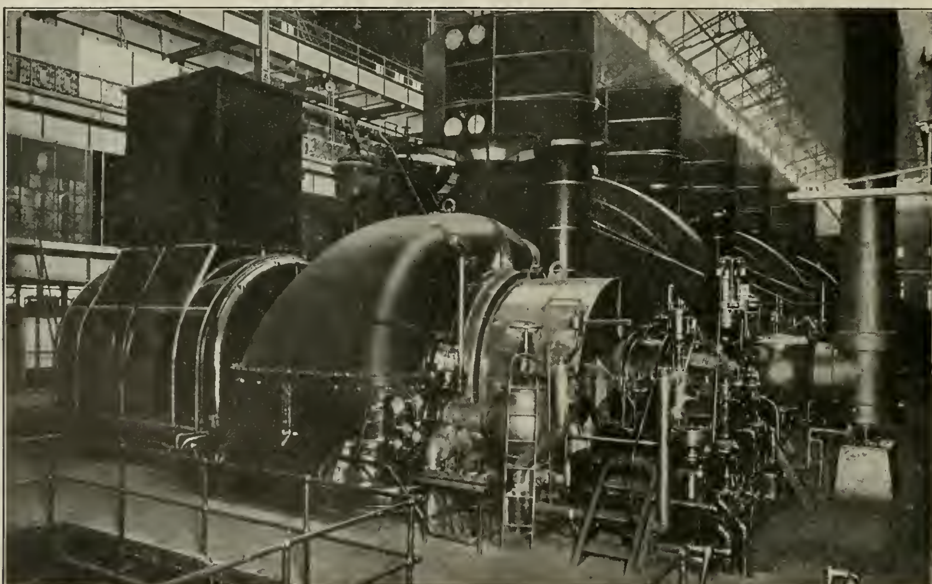

Fig. 1 One of the Three 30,000-Kw. Turbines Installed at the 59th St. Power Station of the Interborough Rapid Transit Co. in 1920

The Turbine Units

Two of the 30,000-kw. units, Nos. 7 and 8, were installed in the space formerly occupied by the three lighting units mentioned in the preceding paragraph, while the third turbine, unit No. 12,

[1] Mechanical Research Engineer, Motive Power Dept., Interborough Rapid Transit Co.

Paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. Slightly abriged. All papers are subject to revision.

[1]Trans. Am.Soc.M.E., vol. 38, page 655.
[2]Trans. Am.Soc.M.E., vol. 32, page 69.

see Fig. 1, was installed at the western end of the station. The great concentration of power possible with modern turbines is strikingly shown by the space they require as compared with that for reciprocating engines. The maximum capacity of the engines visible in the figure is but 26,250 kw. while that of the turbine in the foreground is 35,000 kw.

The general arrangement of unit No. 12, upon which the tests were conducted, is shown in Fig. 2. The turbines are of the straight Curtis impulse type, having twenty pressure stages, each pressure stage consisting of one velocity stage. Fig. 1 is a close view of the governor end of the turbine and shows the auxiliary oil pump, etc. driven by a small steam turbine, the speed of which is automatically controlled by the oil pressure. In addition to the cooling effect of the oil, the bearings are further cooled by the circulation of condensate through water jackets.

As all auxiliaries in the station are steam-driven, a connection has been provided in the turbine through which any excess auxiliary steam may be injected. This connection is at the 16th stage of the turbine.

The generators are three-phase, star-connected, generating 25-cycle current at 11,000 volts. Excitation current is furnished at 250 volts. The generators are cooled by a circulation of air

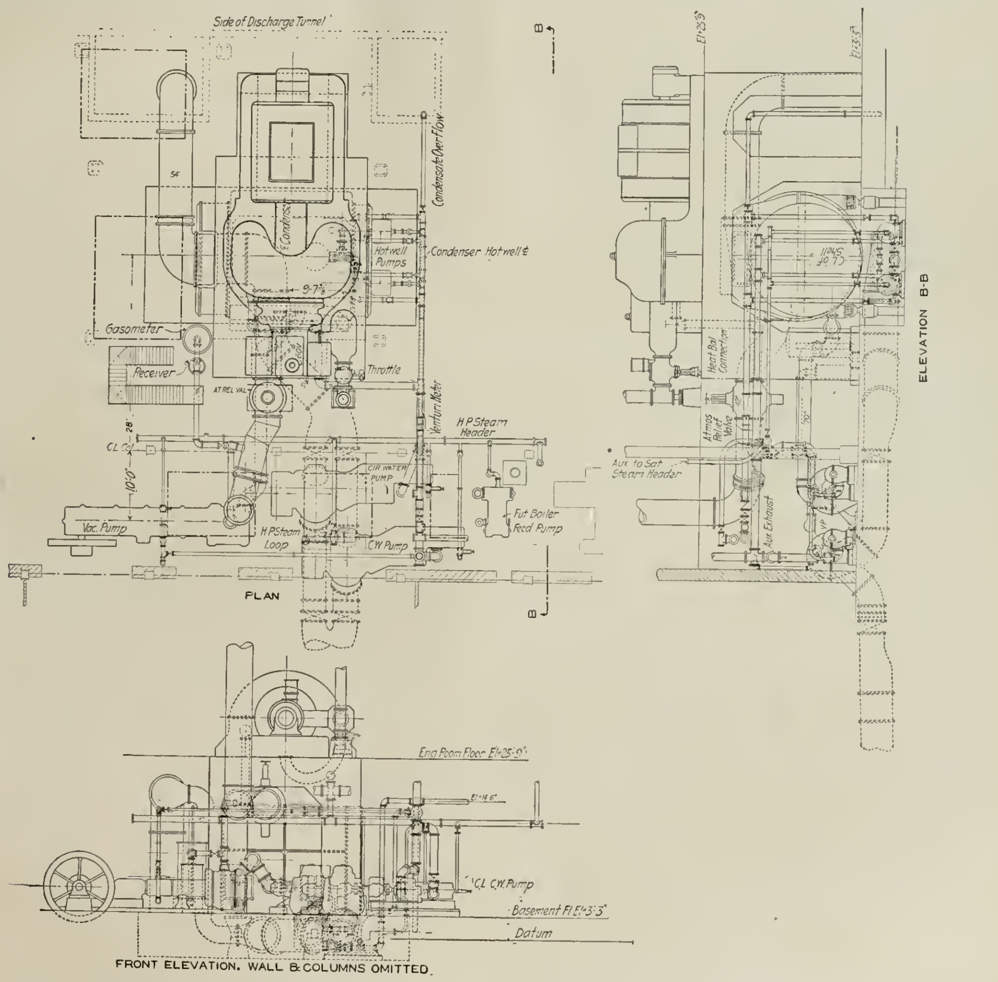

Fig. 2 General Arrangement of Unit No. 2

The normal steam pressure at the throttle is 225 lb. per sq. in. abs., with a superheat of 150 deg. fahr. exhausting into a vacuum of 29 in. Hg referred to a 30-in. barometer at 58.1 deg. fahr. The speed is 1500 r.p.m. In addition to the primary steam inlet, a secondary valve is provided which opens after the load reaches 24,000 kw. and which enables the turbine to carry a load of 35,000 kw. The generator is designed so that this load may be carried continuously.

Water-sealed glands are used which obtain their water supply from the condensate discharge. A self-contained lubricating system is provided. The oil is circulated through the coolers and bearings by means of a pump driven from the turbine shaft. For starting up and emergency purposes a separate pump is provided which is maintained by a fan which forms an integral part of the generator. The air is drawn from the turbine-room basement and discharged from at top of the generator into the turbine-room through a short stack which may be seen in Fig. 1.

Condensers and Auxiliaries

The condensing equipment for each unit consists of one single-shell two-pass Worthington condenser, two Worthington centrifugal circulating pumps each driven through reduction gears by Kerr turbines, two Worthington centrifugal condensate pumps each driven by a General Electric turbine, and one Laidlaw-Dunn-Gordon dry-vacuum pump. The general arrangement of the condensing equipment is shown in Fig. 2.

Each condenser contains 50,000 sq. ft. of tube surface made up of 10,760 tubes 18 ft. long, 1 in. in outside diameter and of No. 18 B. W. G. thickness. The condenser is of the two-pass type, the water entering the bottom and passing out from the top. As the condensers are mounted on springs, rubber expansion joints are inserted in the circulating-water lines.

Each circulating-water pump is capable of delivering 30,000

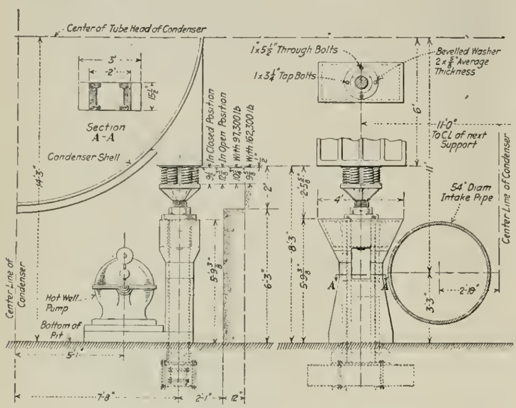

Fig. 3 Spring Supports for Condenser

gal. of water per min. against a total head of 37 ft. The turbines which drive these pumps operate at 3950 r.p.m. This speed is reduced to 395 r.p.m. through Kerr reduction gears. The impellers are made of bronze and are of the enclosed or shrouded design.

Each condensate pump is capable of delivering 950 gal. per min. against a discharge head of 60 ft. The turbine and pump both operate at a speed of 1500 r.p.m.

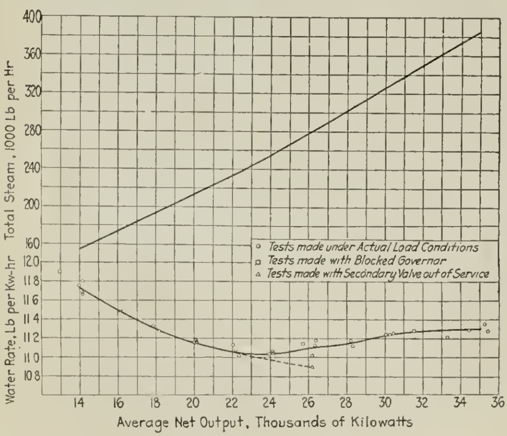

Fig. 4 Water-Rate Curve and Willans Line for 30,000-Kw. Turbine

Steam pressure, 225 lb. abs.; superheat, 150 deg. fahr.; vacuum, 29 in. Hg, referred to a 30-in. barometer; water-rate factor, 0.985. Curve based on tests Nos. 10 to 44, inclusive (excluding special tests with blocked governor and test with secondary valve out of service).

The dry-vacuum pumps are of the single rolling-mill frame two-stage rotative type, with poppet-valve steam cylinder and two-stage water-jacketed vacuum cylinder.

Foundations

Two of the units, Nos. 7 and 8, were installed on the foundations which formerly carried the three 1250-kw. 60-cycle lighting units mentioned earlier. However, it was necessary to alter these foundations to some extent in order to receive the new turbines. The third turbine, unit No. 12, was installed on new structural-steel foundations encased in concrete.

As no expansion joint was provided between the turbine and condenser, it was necessary to mount the condenser on spring supports so as to take care of the expansion and contraction. These spring supports are shown in Fig. 3.

In order to facilitate the setting of these springs and also to provide a means for detecting and adjusting for any fatigue which might occur in them, hydraulic jacks were incorporated in the condenser supports as shown in Fig. 3. As the procedure followed in setting these springs may be of general interest, a brief description will be given. After the erection of the condenser and circulating-water pipe had been completed, with the exception of making the

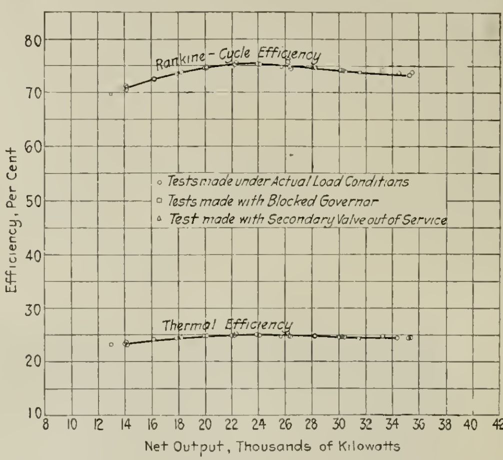

Fig. 5 Rankine-Cycle and Thermal Efficiency Curves for 30,000-Kw. Turbine

Steam pressure, 225 lb. abs.; superheat, 150 deg. fahr.; vacuum, 29 in. Hg, referred to 30-in. barometer. Curves based on tests Nos. 10 to 44, inclusive (excluding special tests with blocked governor and test with secondary valve out of service).

joint between the condenser and turbine, the condenser was raised while empty, by means of the jacks, leaving $^3/_8$ in. clearance

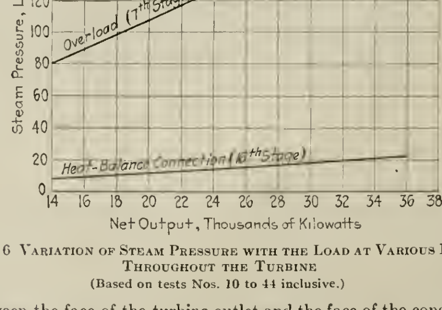

Fig. 6 Variation of Steam Pressure with the Load at Various Points Throughout the Turbine

(Based on tests Nos. 10 to 44 inclusive.)

between the face of the turbine outlet and the face of the condenser inlet. The load on each of the four supports was then determined by noting the oil pressure in the jacks. It was decided that, with the

condenser empty and cold, the downward pull on the turbine should not be less than approximately 17 tons. The distance that the joint between turbine and condenser would have to be pulled in order to give this load was estimated from the modulus of elasticity of the turbine and condenser metal. The condenser was then raised to within the predetermined distance of the turbine outlet, which was found to be 0.231 in., after which the lock nuts on the jacks were screwed home and the condenser bolted to the turbine. The load on the springs was then determined with the condenser still empty by noting the pressure required to just raise the lock nuts. Every few months the load carried by the springs will be determined in this manner and compared with the load which existed when the condenser was first bolted to the turbine. Any fatigue which may develop in the springs will be compensated for by screwing the lock nuts down.

It was found that the minimum condenser load carried by the turbine with the condenser shell empty was approximately 17 tons, which checked with the established minimum. As the water required to fill the condenser amounts to approximately 60 tons, the load on the turbine increases to 77 tons when the circulating-water pumps are started. However, as the result of a slight expansion of the condenser which takes place when it is warmed up, the springs are compressed and a small part of this load is transferred to the supports, reducing the load on the turbine to approximately 70 tons under operating conditions. Immediately after shutting down and while the condenser is still warm but drained, the load on the turbine is reduced to 10 tons. It will thus be seen that the condenser load on the turbine varies from 10 to 77 tons. The total weight of the condenser varies from 180 to 240 tons.

Turbine Tests

The equipment used for conducting the turbine tests consisted of two large water-weighing scales for measuring the steam consumption, three single-phase rotating standard watt-hour meters for measuring the output, and all the necessary thermometers, gages and mercury columns for determining temperatures, pressures and vacua as recorded in this report.

The water-weighing scales had a capacity of about 25,000 lb. each. These scales were very carefully calibrated several times throughout the tests by standard test weights and the total steam consumption corrected accordingly. The rotating standard watt-hour meters which were used for measuring the output were calibrated before and after the tests by the Electrical Testing Laboratories, New York City. It is believed that both the input and output were measured within an accuracy of 0.25 per cent. All thermometers and gages were also calibrated in the usual manner. The specific gravity of the mercury used in the vacuum columns was determined and corrections made accordingly. The readings obtained from the mercury columns were further corrected for me-

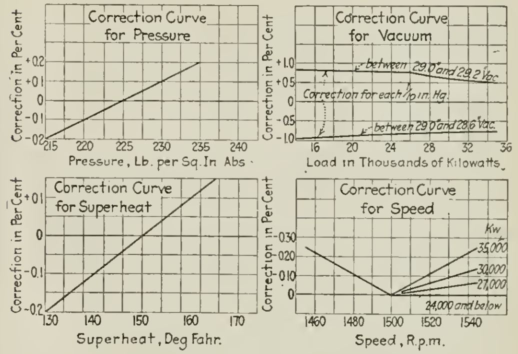

Fig. 7 Curves for Correcting Steam Consumption to the Standard Conditions

[4] Tests Nos. 26, 27, 28 and 29 made with operating governor adjusted to limit maximum loads to the values shown in the second column.

[5] Test No. 16 made with secondary valve out of service.

[6] Test No. 38 made without load on generator, with generator field current adjusted to give normal voltage on open circuit.

[7] Test No. 39 made without load on generator, generator field not excited.

niscus, temperature, and barometer reading. The barometer reading was obtained from the local U. S. Weather Bureau.

Most of the tests were of three hours' duration. With the exception of a few special tests, the turbine was operated under normal conditions in so far as type of load was concerned. The load was controlled from the switchboard through the remote governor-control system provided for that purpose. This method of controlling the load subjected the turbine to the full swings of the railroad load.

Table 1 gives the numerical results of the turbine tests, while the performance is shown graphically in Figs. 4, 5, and 6. Fig. 4 gives the total steam consumption and water rate of the unit, while Fig. 5 gives the thermal and Rankine-cycle efficiencies. From these curves it will be seen that the lowest water rate obtained while operating under normal conditions was 11.03 lb. per kw-hr., while the highest Rankine and thermal efficiencies obtained were 75.5 per cent and 25.0 per cent, respectively. As stated above, all tests with the exception of seven were conducted under operating conditions.

In order to determine the effect of the swinging load on the steam consumption, four tests were conducted with the governor blocked so that the unit operated under a steady load. These tests are shown in Figs. 4 and 5 by the small squares. It will be seen that there is no improvement in the efficiency under the steady load conditions at the loads selected for these tests. When

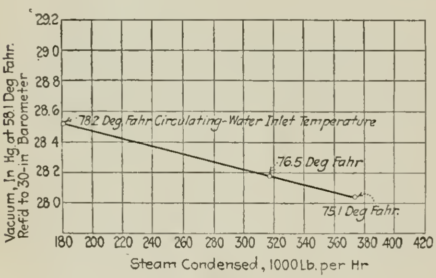

Fig. 8 Curve Showing Vacuum Obtained During Condenser Test

Based on tests Nos. 2, 3 and 4. Circulating-water inlet temperature varied from 5.1 deg. fahr. to 78.2 deg. fahr. Condenser surface, 50,000 sq. ft.

the turbine is operating under normal conditions and carrying loads from 22,000 kw. to 25,000 kw. the secondary valve is continually opening and closing, which no doubt reduces the economy somewhat. If steady load tests had been conducted within this range the points would have probably fallen on the dotted curve. The test shown by the small triangle in Figs. 4 and 5 was run with the secondary or overload valve closed and out of commission, while the load was adjusted so that the primary valve was wide open. As is to be expected, the lowest water rate was obtained while operating in this manner. Since the completion of these tests the governor cams have been modified so that the opening of the secondary valve is delayed. This may improve the economy to some extent near and at the best load point; however, no tests have been conducted to determine just how much improvement has been accomplished.

Test No. 38 was run without any load on the generator, but with the field excited to give normal voltage on open circuit. The actual steam consumption per hour during this test amounted to 17,850 lb. Another no-load test was conducted, but without any excitation, during which the actual steam consumption amounted to 16,090 lb. per hour. No attempt was made to correct the steam consumption during these two no-load tests, due to the vacuum being low and outside the range of the correcting curves.

TABLE 2 SUMMARY OF CONDENSER AND DRY-VACUUM-PUMP TESTS

Number of Test	2	3	4
Condenser Tests			
Average load, lb. steam per hour	180,666	317,000	373,666
Duration of test, hours	3	3	3
Barometer, at 58.1 deg. fahr.	29.93	29.93	30.07

The Necessity for Improvement in the Design and Operation of Present-Day Locomotives

By H. W. Snyder,[1] Lima, Ohio

In view of the demands of constantly growing passenger and freight traffic, the most urgent problems confronting locomotive designers and operating officials are, in the opinion of the author, those of increasing the capacity and efficiency of the present-day locomotives. As the limit of size of cylinders and of boilers due to road clearances has practically been reached, it is evident that any increase in the hauling capacity of a locomotive without increasing its size must come about through the employment of special devices. The superheater, brick arch, and mechanical stoker have all shown their desirability in this respect. Two other devices yet to be adopted in this country are the feedwater heater and the variable exhaust, both of which have given satisfaction in Europe.

After a brief discussion of engine problems, the paper proceeds to the consideration of the design of main and side rods and crankpins to withstand the tremendous piston thrust to which they are subjected in large engines; the difficult problem of counterbalancing; frame design and cross-bracing; driving-box brasses; means for temporarily increasing tractive power on critical grades and for starting heavy loads; ash-pan design; and lubrication.

In conclusion, it is stated that the present need is to apply the many labor-saving and capacity-increasing devices which have already been worked out and are giving satisfactory service, and at the same time look forward to the possibilities of applying other devices which have already proved that they are well worth consideration and are of sufficient importance to warrant their adoption.

No one, it is believed, will dispute the fact that present-day operation of high-power locomotives is one of the most vital questions with which our railroads are concerned. The demands of constantly increasing passenger and freight traffic have brought about a constant increase in size and power of our locomotives.

It has not been so many years since an engine of 25,000 or 35,000 lb. tractive power was sufficient to take care of all requirements. Twenty years ago cylinders 22 or 23 in. in diameter were considered as about the limit in size. Constantly increasing demands on motive power since that time have brought us to the huge Mallet engines with tractive powers of from approximately 150,000 to 175-000 lb. Our simple engines have increased from 20-in. or 21-in. diameter cylinders up to 31-in. cylinders, with a tractive power ranging from around 35,000 lb. to 83,000 lb. In view of the rapid strides that have taken place in increasing the size and power of locomotives within the last few years, it seems rather out of place to predict that the maximum has been reached. It is also true that the use of improved devices has made possible the satisfactory operation of the large locomotives of today. Everything seems to indicate that we have not reached the maximum capacity of the locomotive even within the present limits of clearance and rail load, and we may expect to see these same engines made far more powerful and economical by the application of devices which are now available or which are already being given serious attention.

In view of the foregoing, the most vital matter which confronts locomotive designers and operating officials is that of increasing the capacity as well as the efficiency of the locomotives which we have today, and in the following paragraphs an attempt will be made to draw attention to some of the problems involved and upon the proper solution of which depends their success.

Combustion and Steam Generation

In order that large engines may operate properly, it is of course necessary that a sufficient supply of steam be furnished to cylinders so that they can be made to produce their maximum horsepower. It is not enough to provide a given number of square feet of heating surface in the firebox and the tubes—it is necessary that we take into account proper construction of the boiler, necessary firebox volume to produce the best possible combustion of fuel, and the design of grates so that fuel will be economically burned to such an extent only as required by the maximum evaporation of the boiler.

In producing heavy motive power it has been necessary on account of prohibitive axle loads to apply a sufficient number of axles under the engine to reduce the individual axle load to within reasonable limitations. This has lengthened out the engine to such an extent that boiler design and maintenance have become a serious problem. In the first place it is necessary to design a boiler that will properly function with the other vital parts of a locomotive. At the same time the length has become such that the use of combustion chambers is a necessity to avoid a prohibitive length of tube. Large engines have been constructed with a tube length of 25 ft. and it seems that no definite rule has been established as to what the limit of length of tube of a given size should be. Tubes 2 or $2^1/_4$ in. in diameter in excess of 20 ft. in length however, are questionable, and this feature should be looked into carefully before a decision is reached.

The application of a long combustion chamber requires a large number of additional staybolts, and it would naturally be expected that a boiler of this kind would require more staybolt attention. Complete as well as partial installation of flexible staybolts has met with varying degrees of success on many railroads, but the consensus of opinion seems to be that their application goes a long way toward overcoming staybolt trouble. It has been proved by experiment that if flexible stays are properly applied to the boiler when built, while they may make a slight movement during the firing up of the locomotive, after the boiler has become completely heated and steam pressure raised these stays assume their original position. Although long combustion chambers require more attention in maintenance, this will be offset by the increased firebox volume and the resulting better combustion.

On account of height limitations, the height of the dome as well as the steam space in the boiler has been reduced to such an extent that difficulties are being encountered with the proper life and maintenance of superheater equipment, because too much water is drawn over through the throttle into the superheater. This is a question requiring experiment to determine as nearly as possible the minimum steam space which should be provided for boilers working on various grades. The height of the dome has a great deal to do with obtaining dry steam, and in the opinion of the author consideration should also be given to the height of the throttle above the water line as well as to the steam space in the boiler. Considerable development on this subject is now well under way and we can confidently expect results of value in the near future.

We have about reached the limit of size of cylinders and size of boiler due to road clearances, and to undertake to provide additional road clearance on practically all of the main lines today would mean a total expenditure of money entirely out of proportion to the benefits that would accrue.

On account of the apparent limitations of piston thrust and road clearances, the greatest problem we have with our large locomotives today is to increase their capacity without exceeding greatly our present sizes. Anything to increase the hauling capacity of the locomotive without increasing the height and width limitations under which the locomotive must work might be called an essential capacity-increasing device. A few of these with which we are most familiar and which have proved beyond doubt their desirability are the superheater, the brick arch and the mechanical stoker. There are possibilities of still further increasing the efficiency of the superheater without increasing the size of the boiler in which it must operate. There are also possibilities and constant improvements in the design of brick arches which lend to higher evaporation and better combustion of fuel. It has been stated that when a locomotive requires as much as 6000 lb. of coal per

---

[1]Mechanical Engineer, Lima Locomotive Works, Mem. Am.Soc.M.E.

Abstract of a paper presented at the Spring Meeting, Chicago, Ill., May 23 to 26, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

hour it has gone beyond the limits of the ordinary fireman. Automatic stokers have been in use so long that their dependability for heavy power is no longer in question. Many men are studying this particular feature of locomotive design and operation, and we may confidently expect in the future a gradual increase in the efficiency of these mechanisms.

It has been proved without a doubt in foreign countries that the feedwater heater is an essential capacity-increasing device as well as an economical addition to the locomotive. In Germany they apparently do not now consider producing large locomotives without this device. In this respect, then, it would seem that we are somewhat behind the Europeans, and there is no doubt that in the near future when the economies that can be effected by its use are realized it will become almost as general as the superheater today.

Another small item which has received only passing attention in this country is the variable exhaust. As is well known, a variable exhaust that can be properly operated and which will not require much maintenance attention will have a great tendency to relieve high back pressure at high speeds, and its operation will also provide the necessary draft at slow speeds. European locomotives in a great many cases are equipped with such a device which seems to give satisfaction.

The Engine Proper

There have been no radical changes in the general design of cylinders. The use of outside steam pipes has resulted in advantages both from a casting and maintenance standpoint. It would seem well worth while to consider a design of cylinder by means of which the weight could be reduced to a great extent, permitting of additional weight of other parts and thereby increasing the capacity of the locomotive.

The design of valve gears has received a great amount of attention and many accepted types are now available. In all of these every effort has been to better the steam distribution. In maintenance we are far ahead of engines used twenty years ago. There is yet, however, much to be desired in steam distribution, and this subject will bear as careful study in the future as it has in the past.

Power Transmission

When we consider that as much as 150,000 lb. piston thrust is being transferred through a single main rod and from this into the driving wheels of a locomotive, it is not difficult to understand why troubles are experienced with main crankpins and particularly side-rod bearings at the main pin. In order to provide the proper strength to take care of this tremendous thrust, it has been necessary to design extremely heavy main and side rods. Further, the inertia forces, particularly in drifting, at times reach figures that are even greater than the piston thrust. Practically all of this must be taken care of through the main crankpin and the necessary connections to the side rods at this point.

All are familiar with the efforts made to produce a steel that would give a higher elastic limit than the ordinary high-carbon open-hearth steel successfully used until engines reached their present proportions. The employment of such steel for side rods, main rods and piston rods has been principally confined to heat-treated and quenched forgings, which are considerably lighter in section than when the ordinary open-hearth annealed forgings were used. Steel has also been produced which gives a high elastic limit and which can be successfully used with ordinary annealing. The use of such a steel does away with quenched forgings and permits of rods being heated for closing in straps and similar work without destroying the quality of the material as is the case with quenched forgings.

Main and side rods have been produced and have been in successful operation for the past few years in which the piston thrust is carried directly from the main rods to the side rods back of the main wheel. This does not in any way reduce the piston thrust that must necessarily come on the main rods. At the same time, however, it does reduce very considerably the piston thrust that must be transferred through the main crankpin into the side rods, thereby alleviating to a very great extent the troubles that have been experienced with large side-rod connections at the main pin. Such a design does not increase the total weight of the rods to an extent likely to cause any appreciable increase in difficulties from a counterbalance standpoint.

It is impossible to take into account all the stresses produced in rods when a locomotive is in operation, and for this reason the allowable fiber stresses in tension, compression and bending must be small in comparison with the elastic limit ordinarily obtained in such forgings.

Rod design is a study in itself and presents a subject the details of which cannot be covered in a paper of this nature. Hollow-bored piston rods, light designs of crosshead and piston, the use of high-tension steel for side and main rods, as well as the use of hollow-bored crankpins, are familiar to all. More careful attention should be paid to the quality and upkeep of rod bearings, and every endeavor should be made to provide bearings of such quality and design that renewals will be reduced to a minimum.

Before the advent of our present-day large locomotives with their tremendous piston thrust it was not a particularly difficult matter to design a suitable main crankpin. In order for it to be of sufficient size to withstand heavier piston thrust and still maintain the fiber stress within workable limits, it was found necessary to increase the diameter proportionately. This brought up the question of rubbing speed. It is a well-known fact that if the rubbing speed is too high, bearings will heat and wear very rapidly regardless of the bearing pressure. A main pin designed properly for heavy piston thrust must therefore be so proportioned that the length will bear a certain relation to the diameter within very close limits. On account of the necessity for keeping cylinder centers as close together as possible because of road clearances, if a proper length of main pin is obtained, its proper size presents a difficult proposition. This is one of the great difficulties which the author is confident will be overcome in the future by the proper application of a design previously mentioned, wherein a large part of the piston thrust is transmitted directly from the main rod into the side rod, thus reducing the force that previously has been taken through the comparatively short and large-diameter main side pin.

Counterbalance

There is a great diversity of opinion in regard to the proper amount of counterbalance which should be applied to locomotives. We ordinarily think of a locomotive being counterbalanced properly when it will ride satisfactorily and without excessive vibration, and it seems that this is the rule by which counterbalance is judged. There are in operation heavy Santa Fe type locomotives which have between 35 and 40 per cent of the reciprocating weights counterbalanced, and they are said by traveling engineers to ride easy. The author believes that with our present heavy engines with long wheelbase it is not necessary to balance as much as 50 or 55 per cent of the reciprocating weight. In fact, it is quite possible that we may be able to counterbalance a smaller percentage of reciprocating weight than has heretofore been attempted, especially for long, heavy engines, provided the revolving weights at the main pin can be properly taken care of. Every effort, however, should be made to balance all of the revolving weights on the main pin. If, for example, we lack 400 lb. of balancing the revolving weight on the main pin, the effect on the track is exactly the same as if we had 400 lb. of counterweight on any of the other wheels to balance reciprocating parts.

On account of the extremely heavy weight required at the main pin in order to have the proper strength of parts, particularly for large freight locomotives, it is a difficult matter to balance very much—if any—more than the revolving weights at this point. This being the case, if as much as 50 or 55 per cent of the reciprocating weights is to be balanced, it is easily seen that all of the counterweight for reciprocating parts must be added to the counterweight in the wheels other than the main. Thus, in order to balance a high percentage of reciprocating weights on engines of this class, it is necessary to add counterweight to the wheels other than the main to such an extent that track stresses and riding of the locomotive at comparatively high speeds become a very serious question.

The author is of the opinion that no definite set rule can be established in this regard, but that each particular design is a study in itself, and wherever revolving weights at the main pin are encountered such that they cannot be properly counterbalanced,

steps should be taken to provide the best means possible of reducing revolving weights at this point as well as providing reciprocating parts as light as possible consistent with strength. This of course has been accomplished in the past by hollow-boring the main pins and piston rods and by using a light design of piston head, which indicates that a steel having a high elastic limit with the proper elongation and reduction of area should be employed.

The Running Gear

On account of the large increase in the size of cylinders of present-day heavy locomotives over those used several years ago, the cylinder centers have been spread until they have reached practically the clearance limitations of the railroads; and the necessity for larger journals to carry properly the increased axle loads has caused the frame centers to be brought nearer together.

This condition increases very materially the distance from the center of the cylinder to the center of the frame, which of itself produces greater strain in the frame and at the same time increased pressures on the driving-box bearings as well as on shoes and wedges. In addition to the above, piston thrusts have increased from approximately 65,000 lb. to approximately 150,000 lb., and means must be provided to properly take care of the increased piston thrust along with the increased overhang.

Fig. 1, it is believed, shows very clearly the increased forces that a frame must stand in order to properly take care of the tremen-

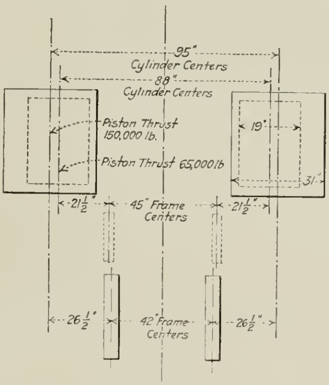

Fig. 1 Diagram Showing Increase of Overhang of Cylinders in Present-Day Locomotives

dous increases in piston thrust as well as the increased leverage caused by the very considerable lengthening of the distance between the cylinder centers and the frame centers.

Substantial and sufficient cross-braces should be applied between the frames and rigidly bolted thereto to form a rugged structure which will not rattle to pieces. Sufficient bearing for bolts and adequate bolting flanges are a very important feature. At the same time it must be borne in mind that there is a possibility of tying up the frame so rigidly that there will be a tendency for failures ahead of the front pedestal and just back of the cylinder fit at a point where it is practically impossible to obtain sufficient reinforcement.

It seems as though the design of driving boxes and driving-box brasses had not successfully kept pace with the rapid increase in piston thrust. It is very evident that we shall have trouble in taking care of driving-box brasses until a suitable design is produced—one in which the brass will cover much more of the front and back projected area of the journal than is now the case. Many experiments have been tried, and in many cases they have gone beyond the experimental stage and have proved to be very satisfactory. Among these are driving-box brasses cast into the driving box. Many boxes are in use today where the brasses are keyed into the box, making them readily removable for replacement. However, the author feels that none of these has approached the solution to the problem, which lies in producing a design that will surround the journal with a bearing as completely as possible and still lend itself to comparatively easy maintenance and reasonable cost of application.

Guiding and Trailing Trucks in Connection with Long Wheelbase

Santa Fe type engines with 22-ft. rigid wheelbase are not uncommon. Engines of this type and of this size will weigh in the neighborhood of 400,000 to 420,000 lb. When we stop to think that to move this tremendous mass of material around a 16- or 18-deg. curve a force of many thousands of pounds is required, is it any wonder that we obtain rapid flange wear and the necessity for returning tires before the proper amount of mileage has been obtained? In the majority of cases, it is believed, the force necessary to properly curve an engine of this kind has been applied at the front truck and the first driver. In most cases types of leading trucks have been used which produce a very small resistance on curves of small degree. In order to prevent rapid flange wear as well as to overcome the development of lateral play unnecessarily, designs have been produced which will give a high initial resistance of the front truck and provide a lateral motion for the front driver with adequate resistance so that some of the guiding force is transferred back to the second pair of drivers.

Since locomotives operate the greater part of the time on tangent track, it is necessary to have a high initial guiding resistance which will not be increased when curving. In other words, a flexible wheelbase is produced which has all the requisites of the ordinary rigid wheelbase, but at the same time will overcome many of the difficulties now encountered in an attempt to operate engines of this size and length. Many designs of trailing trucks have been produced with the idea in mind of helping to remedy the conditions which have been noted above. These of course have met in a way the conditions which it was necessary to overcome. What is needed is a positive centering device whose resistance will be adequate initially, can be always depended upon, and which will not mount up to prohibitive figures under the maximum swing of the trailing truck.

In addition to the foregoing, some work has been done in the way of producing a design by means of which the lateral play in locomotive driving wheels can be taken up without removing the wheels from under the engine or taking the boxes off from the axles.

The advent some years ago of the power reverse gear overcame one of the great objections that engineers had too large locomotives. It is a fact that it is almost impossible for one man to reverse one of our large locomotives equipped with the ordinary hand reverse lever. Power reverse has come to be an essential part of engine equipment and has been found to be economical even though it may be used on a locomotive which could be comparatively easily reversed by hand.

Probably no one thing contributes more to the failure of side rods than the improper adjustment of shoes and wedges. If these are allowed to run loose, stresses in the side rods will amount to a very high figure, and if they are improperly set up, the driving wheels are very likely to be out of tram. This in itself brings undue stresses on the rods, which in time will unquestionably produce failures. The author feels that there are many cases where in attempting to overcome the failure of side rods we have deliberately increased their sections without giving due consideration to the cause of failure. Consideration of the foregoing brings us to the point of providing an adequate automatic adjustment of the wedge so that the difficulties mentioned will not be encountered.

Means for Increasing Nominal Tractive Power

All railroads have points on certain divisions where there is a critical grade or the necessity of starting a heavy load under adverse conditions. At such places increased tractive power is required which is not needed elsewhere. We are therefore confronted with the problem of producing a device which can be set to work to increase the tractive power of a locomotive in such cases, thus enabling the engine to take its full tonnage over the entire division. This device should be so made that it can be applied when necessary and thrown out when the additional tractive power is not required. Designs have already been produced wherein an additional tractive power of 8,000 or 10,000 lb. has been applied to the trailing trucks of large locomotives. There is also a possibility of applying such a device to the tender truck, thus availing

ourselves of the adhesive weight of the tender to help boost the engine over the critical points in a division. There is always present a possible potential boiler capacity which can be brought out by the use of a variable exhaust or other device sufficient to obtain rapid combustion at slow speeds.

The Ash Pan

The question of ash pans is also one needing serious consideration. There are in use a number of rules stating what the proper air opening in the ash pan should be, and while many of these rules have in a way proved satisfactory, it would nevertheless seem that to get at the question logically we should determine the amount of coal that can be burned economically per square foot of grate and then on this basis provide an ash-pan air opening that will give the required amount of air to burn satisfactorily the maximum amount of coal which is expected to be consumed. The amount of air that will flow through a given opening in the ash pan, it is believed, can be very closely approximated from the vacuum produced in the smokebox. This of course is only a suggestion, and it may be that when the question is looked into more carefully a more desirable and accurate method of determining the required ash-pan air opening may present itself.

Lubrication

With our present high superheat the proper introduction of oil into the cylinders and valves of a locomotive is worth serious consideration. In many cases oil has been provided to both the cylinder barrel and the steam chest of superheater locomotive, and in other cases it has been provided to the steam chest alone. Both methods have given apparent satisfaction, but it is a difficult matter to state which is the better.

It is common practice in European countries to provide a force-feed lubricator located very close to the cylinder, with a pipe to each end of the piston-valve steam chest. This oil supply opens directly over each end of the valve when it is in central position. In addition an oil pipe is supplied to the cylinder at its center. It is reported that by this method there is less carbonization of the oil than when it is fed into the steam pipes or into the center of the piston-valve steam chest.

In order to increase the tonnage which a locomotive can haul it is just as vital to decrease the resistance as to increase the power. Now it is not an impossibility to provide roller bearings for passenger cars, and there seems to be no reason why they cannot be used on freight cars. The reduction of rolling resistance and the better facilities for lubrication which would be provided would be sufficient in time to overcome the necessary expense.

This question of lubrication may as well apply to other parts of the locomotive. The proper grooving of side-rod and main-rod brasses, or the use of babbitt inserts, are questions that should be taken up in connection with lubrication of these parts.

Conclusion

In summing up the situation, it may be said that the use of the superheater alone has increased the capacity of locomotives when compared with saturated engines of the same design to such an extent that no one would think of building a large locomotive for up-to-date railroad service without the application of superheat. We must not content ourselves, however, with what has been done with this one device. What we need to do now is to avail ourselves of the opportunities offered in the application of many of the labor-saving and capacity-increasing devices which have already been worked out and are giving satisfactory service, and at the same time look forward to the possibilities of applying other devices which are yet in their infancy, but which have proved beyond doubt that they are well worth our consideration and are of sufficient importance to warrant their adoption. Without the capacity-increasing devices which have been mentioned the large locomotive of today would be impossible—it could not be operated satisfactorily. Our large engines are an absolute justification of these improvements. Further developments are ready at hand and in their use lie the possibilities of still more powerful and economical transportation units built to operate within our present limitations of clearance and permissible rail loads.

MID-WEST CENTRAL-STATION POWER

(*Continued from page 444*)

the highest tension in the Middle West—with some distribution at 70,000 volts.

In Wisconsin the important hydroelectric developments on the lower Wisconsin River at Kilbourn and at Prairie du Sac are connected by 66,000-volt lines to Milwaukee and to important manufacturing centers to the south, which are included in the Middle West system. The water powers of the Chippewa River and its tributaries have been developed largely by the Brewer interests. Much of this power goes to St. Paul and Minneapolis over a 120-000-volt line, and to other Mississippi River cities farther south. The distribution to the south and west from St. Paul and Minneapolis is over 66,000-volt lines and 110,000-volt lines owned by the Byllesby Company.

A study of the five principal states of the group represented in Fig. 2 indicates that when power is to be generated by steam it can best be done by central stations in the locality where it is to be used. For example, Chicago, with its large and efficient power houses, is surrounded by power houses of the Public Service Company of Northern Illinois and by those of the Middle West Utilities Company, with all of which it exchanges power, but which nevertheless generally supply the power needed in their immediate respective vicinities. Chicago is connected with Keokuk and Keokuk with Indianapolis and New Albany, and yet the power sent over these lines from its large power houses is small in comparison with that generated and distributed locally along the lines.

Formerly each small country town requiring 50 kw. or more had its own central station, using 20 lb. of coal per kw-hr. As there was no money in that, there came about consolidations of these isolated central stations into small groups, all supplied from the best-located plant of the group. It was found that with an improved load factor and larger units the coal consumption was by this means reduced to 15 lb. per kw-hr. The next step was to connect these groups into larger ones of 5000 kw. capacity, favorably located as regards condensing water and rail connections, having condensing turbines and capable of delivering a unit of energy for 4 lb. of coal. A plant of this size can reach out its arms and gather in all of the power within a radius of thirty miles or so. This is about the most efficient combination of station power and transmission lines, unless it happens that the power demands of the city in which the plant is located are such that the use of generating units up to 15,000 kw. is practicable, in which case a further material improvement in efficiency is secured and warranting the construction of longer lines to reach more remote groups of power, these large plants being interconnected over lines of sufficient capacity to permit them to be mutually helpful.

Such is the plan which is naturally developing, and although its progress must be as slow as the process of consolidation of the properties, it appears that the problem of cheaper power production is working out its own solution along conservative lines and that in time the present systems will merge into larger ones, with one general scheme for generation and distribution, so that areas equal to a state in extent and overlapping state lines shall be under one management.

What, then, about home rule? Many years ago, when "tariff" was the football of national politics, a candidate for the presidency, upon being asked to declare his position on this burning issue, replied that the tariff was a local question and had no place in a presidential campaign. It is by such reasoning that the interests of a utility, stretching for hundreds of miles across the country and supplying power to hundreds of scattered or contiguous communities and to thousands of industries, becomes a local question and properly subject to local regulation as a foreign monopoly by each of the various cities, towns and villages in which it renders service.

Fortunately it is becoming generally recognized that a state-wide industry of this character requires state-wide regulation andt hat for the state to abdicate its jurisdiction, cut it up into sections and parcel out the pieces to the police powers of the various localities in which the utility operates, subjecting it to the vicissitudes of local politics, cannot help that utility to develop and to most economically and efficiently serve those same communities.

Advantages of Large Freight Locomotives, Particularly the 2-10-2 Type

By ALBERT F. STUEBING,[1] NEW YORK, N. Y.

In this paper the author points out the more important considerations involved in a study of the economic value of various types of motive power and demonstrates the complexity of the problem. Probably, he holds, no absolutely correct analysis is possible, and surely no' practicable. The choice of motive power is of extreme importance because the characteristics of the power affect the earnings more than any other single factor and determine the efficiency of operation usually throughout the life of the engine. For this reason the choice of the locomotive should be made with extreme care. The final decision should be based on a definite knowledge of the economies that can be realized, not on unsupported opinion. Engineering methods are essential in working out the solution, and the study of the problem offers a field for constructive coöperative work by the members of the engineering societies.

PROBABLY the briefest presentation of the advantages of large locomotives is that made by James J. Hill: "Receipts are by the ton- and passenger-mile; expenses are by the train-mile." It is not to be expected that such a general statement will hold good in all particulars, nevertheless it is true that a large proportion of operating expenses decrease as the train load increases, although not in the same proportion as the decrease in train-miles. Under the operating conditions existing on most of the main-line mileage of this country, the greatest possibilities for economy are probably still to be found in the adoption of locomotives of high capacity.

The large locomotive, designed merely for high rated tractive effort, is not a panacea for operating troubles. The first requisite is a design suited to the conditions of the operating territory, the traffic, and the service. The relative advantages of specific designs are a problem in the economics of operation that must be solved by the application of engineering principles. It is a question of adapting the design to the operating and economic conditions and then coördinating the motive power with other facilities.

The adoption of improved power should be only one part of a coördinated program. Every appropriation for larger engines should carry with it, as an integral part, provision for facilities to insure the maximum utilization of the power. Engine terminals, shops, yards, the rolling stock and the track structure itself should be prepared to assist in obtaining the proper operating results. The coördination of facilities deserves careful study. Much better results will be obtained by the use of locomotives adapted to existing conditions where the related facilities cannot be adapted to the locomotive.

The choice of motive power is of extreme importance because the characteristics of the power affect the earnings more than any other single factor and determine the efficiency of operation usually throughout the life of the engine. The problem of introducing new locomotives is similar to the problem of reducing grades and should be studied as thoroughly. The interrelation between the various factors affected affords large opportunities for savings and also for losses. Many investigations have been held up during the past few years and the rapid changes in prices have made earlier data inapplicable. It would seem, therefore, that there is a large field for research in the economic problems of operation when normal conditions are restored.

Most of the available reports on the economic value of heavy locomotives consider comparatively few of the items affected. The comparative costs of wages of train crews, of fuel and water, and of repairs to locomotives are often the only items considered. In some few cases the comparative mileage and fixed charges on the investment in motive power have been computed. This is not sufficient to determine conclusively the relative merits of various types of power. The locomotive has a direct or indirect influence on many items of expense in the maintenance of way, maintenance of equipment, and transportation accounts. The real problem in determining the value of a locomotive is to find the effect that its operation will have on the sum total of these accounts, and the results of a thorough study should more than justify the labor involved.

It is the purpose of the following paragraphs to point out some aspects of the problem that apparently are deserving of attention. A search through the literature on this subject has failed to disclose fundamental data on these questions that are applicable to present conditions.

The Effect of Motive Power of Maintenance-of-Way Expenses

Some roads have reached adverse decisions on the adoption of 2-10-2 type locomotives on the ground that the increased cost of roadway maintenance resulting from their use would more than offset the savings in wages. Maintenance-of-way expenses make up about 17 per cent of the total operating expenses, but the greater part of the expenditures are independent of the character of the power. Much of the work of track maintenance is made necessary by the action of the elements, or by the necessity of maintaining the permanent way in suitable condition for fast passenger traffic. The expense which is most directly affected by heavy locomotives with long, rigid wheelbases is rail renewals. Other accounts that are affected to a lesser degree are ties, track laying and surfacing, roadway maintenance, and superintendence.

There is little or no information available as to the comparative effect of four and five pairs of coupled wheels on rail wear and the other accounts affected. The actual effect will vary according to the wheelbase, the curvature of the road, and whether the locomotive has one or more pairs of drivers equipped with lateral-motion devices.

The sum of the maintenance-of-way expenses which may be increased by heavy motive power is about 10 per cent of the total operating expenses, and if the effect is to increase these items considerably the saving will be difficult to make up in other accounts. However, if the wear and tear on the track is merely proportional to the weight of the engine, as is sometimes assumed, light and heavy engines would be on a par as regards these items. The difference of opinion on this question suggests the necessity for a careful investigation.

Maintenance of Equipment

The percentage of the total operating expenses falling in this classification has shown a fairly consistent increase over a considerable period. Locomotive repairs and renewals, which in 1898 amounted to 5.9 per cent, in 1918 had increased to 11.7 per cent. So many factors may influence this ratio that no definite conclusions can be drawn, but it is significant nevertheless.

The principal difficulties in maintaining large locomotives are due to the short life of driving-wheel tires, driving boxes and main-pin bearings. With the proper facilities and proper construction the work of caring for these parts becomes merely a matter of routine running repairs, but where the lack or inadequacy of terminal facilities hampers repairs, the loss of service due to these minor items may become serious.

While the foregoing remarks are confined to some of the more important items of roundhouse maintenance, they are equally applicable to the work of classified repairs. If the shops and shop machinery are not adequate for new power, repair charges will be high and the time out of service will be increased. The cost of these facilities should be considered when estimating the saving that may be effected by new power.

Wide differences of opinion appear to exist regarding the relative cost of maintenance and mileage of 2-10-2 type and Mallet loco-

[1]Associate Editor, *Railway Age*. Jun. Am.Soc.M.E.

Abstract of paper presented at the Spring Meeting, Chicago, May 23 to 26, 1921, of The American Society of Mechanical Engineers. All papers are subject to revision.

motives. While the field for each is to a certain extent distinct, there are districts where either might be suitable and roads that have sufficient data to permit a fair comparison could perform a service by furnishing information that would clear up this question.

A very serious problem in connection with the use of locomotives of high capacity is the effect on the cost of repairs to freight cars. The total amount spent for repairs and renewals is nearly as great as the repairs and renewals to freight and passenger locomotives combined. When the length of trains is increased beyond a certain point, break-in-twos, shifted loads, and damage to the cars in general may increase at a rapid rate. The effect of increasing the length of the train may be serious where the road cannot control the character of equipment in the trains, where the car load is light, the train long, and the lading is subject to damage or of such a nature that it may shift and damage the car. It is significant to note that a study made by N. D. Ballantine showed the time delayed due to car failures was more than twice as great with a Mikado engine, which had a tractive effort of 57,000 lb., as with a Consolidation of 39,000 lb. tractive effort.

A study of car failures in long trains may demonstrate that the trouble is largely due to equipment with weak underframes. If wooden underframes are a serious hindrance to the operation of long trains, the remedy can be applied with little difficulty. While the reinforcement of the remaining cars of this type still in service would require fairly heavy expenditures, it would no doubt be justified by the saving in repair costs and improved operation.

Transportation Expenses

Directly or indirectly, the locomotive affects items in the transportation expenses which amount to about 35 per cent of the total operating expenses. Two of the important items which are reduced almost proportionately as the tractive effort increases are wages of train enginemen and trainmen. The economies in these expenses are considerable and they can be predetermined with a fair degree of accuracy.

Enginehouse expenses likewise are affected by the character of the power to an extent depending on local conditions. The reduction in the number of units handled will probably cause a slight decrease in the cost per ton-mile unless the new equipment makes additional facilities necessary.

Several miscellaneous items of operating expenses are also affected to some degree, such as accounts affected by collisions and derailments, loss and damage, damage to live stock, clearing wrecks and injuries to persons. The effect of car failures on loss and damage has already been mentioned. In so far as these expenses are due to collisions and derailments, they are increased by an increase in train density rather than by an increase in the length of the train, and would therefore be reduced by the use of locomotives of high capacity.

Fixed Charges

The fixed charges on the motive power seldom exceed three to four per cent of the operating expenses. The difference between the fixed charges on a thoroughly efficient modern engine and a crude design that might be bought to make an insufficient appropriation cover a given number of locomotives, is negligible. However, the difference in the earning power of these two types is quite appreciable and serves to show what large returns can be derived from the additional capital expended for refinements and accessories that give increased capacity and efficiency.

At first thought it might seem that the additional investment for terminals, shops, and shop machinery would add greatly to the capital expenditure and the fixed charges. Under ordinary conditions, however, the cost of roundhouse space required properly to house a locomotive is a comparatively small proportion of the cost of the power. The cost of the shop buildings and machinery is even less important when the added efficiency and decreased cost of repair operations are considered.

Sometimes the introduction of heavy locomotives necessitates strengthening or replacing bridges or laying heavier rail over certain sections. The expenditures involved are often quite large, but the relatively long life of these structures decreases the fixed charges and the additional cost per ton-mile becomes comparatively small and is seldom an important factor in determining the most economical equipment. When new rail must be laid the additional expenditure is a more serious item and the charge would probably not be justified except on a line with relatively dense traffic.

The preceding discussion pointing out the more important considerations involved in a study of the economic value of various types of motive power demonstrates the complexity of the problem. Probably no absolutely correct analysis is possible; surely, it is not practicable. The question is of extreme importance because the possibilities of economical operation are circumscribed by the motive power. For that reason the choice of the locomotive should be made with extreme care. The final decision should be based on a definite knowledge of the economies that can be realized, not on unsupported opinion. Engineering methods are essential in working out the solution and the study of the problem offers a field for constructive coöperative work by the members of the engineering societies.

EFFICIENCY TESTS OF A 30,000-KW. STEAM TURBINE

(Continued from page 454)

$$F = \frac{MW}{C}$$

in which F = water-rate factor; M = minimum water rate obtained; W = mean load between one-half rated load and maximum load, which is the usual operating range; and C = average total steam consumption per hour covering the range between one-half rated load and maximum load.

Using the curves given in Fig. 4, substitutions may be made as follows:

$$F = \frac{11.03 \times 25{,}000}{280{,}100} = 0.985$$

This factor could be expressed by using the ratio between the minimum water rate and the average water rate over the range selected. However, the factor obtained in this manner would not take into account the fact that it is more desirable to obtain flatness in water-rate curves at the high loads than it is at the low loads. By using the total steam consumption as indicated in the expression given above, a fairer comparison is obtained.

Condenser and Auxiliary Tests

Tests were conducted on the condensers and auxiliaries. A summary of the condenser and dry-vacuum-pump tests, which were run simultaneously, is given in Table 2, while the relation between load and vacuum is shown graphically in Fig. 8. In examining the results of these tests and comparing them with the vacuum obtained during the turbine tests, it should be kept in mind that the temperature of the circulating water during the condenser tests, which were run during the summer, was very high, varying from 75.1 deg. fahr. to 78.2 deg. fahr. The methods used in determining the quantities given in Table 2 need no description, with the possible exception of the measurement of the air discharged from the dry-vacuum pump and the steam consumption. The air was measured by a gasometer connected to the discharge of the pump. The steam consumption was determined by condensing the exhaust steam in a small test condenser, after which it was weighed in the usual manner.

Table 3 gives the results of the tests on the circulating-water pump. It will be seen that two tests were conducted on these pumps, one being an economy test while the other was a maximum-capacity test. Only one of the two pumps was running in either test. During the economy test the discharge valve was adjusted to give the normal operating head which exists when two pumps are running, while in the capacity test it was left wide open. The quantity of water pumped was computed by the heat-balance method, which involved the measurement of the main-turbine condensate, its temperature, the temperature of the circulating water in and out, the steam conditions at the main-turbine throttle, load on main unit, etc. The steam consumption of the turbine driving the pump was determined by means of the small test condenser mentioned above. The results of the condensate pump test are given in Table 4.

Chicago Meeting of A.S.M.E. Sets New Standard

Excellent Technical Program Vies with Attractive Excursions and Delightful Entertainments in Largest Spring Gathering

DRAWN by the strong technical sessions, interesting social events and instructive plant visits listed on the program, 1235 members and guests of The American Society of Mechanical Eng'neers registered for the Spring Meeting at the Congress Hotel, Chicago, May 23 to 26. The attendance exceeded that of any previous Spring Meeting, but the large number was but one of the attributes of a successful meeting. The Chicago General Committee had worked hard in the planning of the event and their labors were rewarded by the pleasure of seeing a smoothly conducted affair. The program was full—fourteen sessions, numerous committee meetings and plant visits—but the schedule was rigidly followed and everything was completed in time.

The opening morning of the meeting was devoted to the Council Meeting and registration—the business session commencing at 2.30 in the afternoon, and the following mornings were devoted to professional sessions, the afternoons being reserved exclusively for plant visits. Tuesday evening was assigned to the session on Training in the Industries.

Entertainments

On Monday evening an informal reception was held in the Gold Room of the Congress Hotel. The Chairman of the Chicago Section and the President of the Western Society of Engineers with the officers of the Society greeted those attending the convention. A large number of Chicago members were on hand to assist in making the guests feel at home. The result was a right enjoyable evening.

On Wednesday evening an informal dance was held. The Gold Room was effectively decorated with flags and lights for an affair that was thoroughly appreciated from the first crash of an exceedingly competent jazz band. The floor was crowded and remained so during the evening, except for some few of the elders who drifted out into the corridors for a good chat.

Special attention was accorded the ladies at the Spring Meeting. Tours to the Marshall Field store and the Field Museum were conducted, and on Wednesday, following an automobile ride through the lake-front residential section of Chicago, they were guests at a charming reception at the home of Mrs. Robert W. Hunt.

Plant Visits

Chicago and its remarkable industrial surroundings furnished a fine opportunity for interesting plant visits. The Chicago Committee chose outstanding plants for these excursions and planned the details carefully, with the result that every one of them was faultlessly conducted. A definite number of visitors were assigned to each excursion and in every case the allotment was more than taken up. The plants visited included the Fisk Street Station of the Commonwealth Edison Company; Sears, Roebuck & Company; Illinois Steel Company; Pennsylvania Terminal; Crane Company; Mandel Brothers; Chicago Mill and Lumber Company; Western Electric Company; Pullman Company; Chicago Underwriters Laboratory, and the Yellow Cab Mfg. Company. The following plants were thrown open for inspection and many members availed themselves of this opportunity: Clementsen Company; Green Engineering Company; Hanna Engineering Works; Ilg Electric Ventilating Company; W. A. Jones Foundry & Machine Company; Link Belt Company, and the Joseph T. Ryerson & Sons Company. On Friday morning about seventy-five members visited the pulverized-fuel installation at the Lakeside plant of the Milwaukee Electric Railway and Light Company.

The Local Committee

The entire arrangement of the meeting was under the jurisdiction of the General Chicago Committee, made up of Robert W. Hunt, Honorary Chairman; Herbert S. Philbrick, Chairman; James D. Cunningham, Secretary; Melville S. Flinn, Treasurer; David Lofts, P. Albert Poppenhusen, Arthur L. Rice and Edward P. Rich. The enthusiastic and efficient work of this committee was responsible for a most successfully conducted meeting.

Proceedings of the Business Meeting

PRESIDENT Carman occupied the chair at this session. To promote discussion of a new Constitution, the first item scheduled at the Business Meeting was a paper by Morris Llewellyn Cooke entitled On the Organization of an Engineering Society. This paper was published in full in the May issue of Mechanical Engineering. By previous arrangement the discussion of the paper was placed in the Management Session the following day.

Members of the Chicago Local Committees Whose Enthusiastic Coöperation Contributed so Greatly to the Success of the Largest Spring Meeting yet Held

General Committee

Robert W. Hunt
Hon. Chairman
Herbert S. Philbrick
Chairman

Committee on Meetings and Program in General Charge of the Society's Convention

R. V. Wright
Chairman
A. L. DeLeeuw
W. G. Starkweather
J. W. Roe
L. B. McMillan

The President then introduced John L. Harrington, of Kansas City, Mo., Chairman of the Committee on Constitution and By-Laws, who presented the report of his committee.

Those participating in the discussion included Morris L. Cooke, S. N. Castle, Max Toltz, R. B. Wolf, D. S. Jacobus, P. F. Walker, Charles L. Newcomb, L. C. Marburg, R. L. Sackett, Fred Dorner, Roy V. Wright, W. H. Kenerson, D. S. Kimball, R. H. Fernald, George A. Orrok, L. B. McMillan, Messrs. Nelson, Case, and Jackson (Rock Island), L. P. Alford, R. T. Kent, Charles Penrose and Secretary Rice. The synopsis of their discussion will be published in the next issue in parallel with the Articles proposed.

Special Action on Juniors Voting

Morris L. Cooke, who has an amendment to the Constitution already pending to extend the privilege of voting to Junior Members, sought the sentiment of the meeting regarding this provision, and after considerable discussion the matter was put to vote and carried by a majority of one. This means that Mr. Cooke is entitled to again put his amendment at the Business Meeting next December, and the meeting will vote whether or not it should be submitted to letter-ballot of the membership next March.

Reports of Special Committees

The Standing Committee on Technical Nomenclature presented a progress report on Symbols in Heat Engineering. It was voted that this report be received and ordered printed in Mechanical Engineering for discussion.

The Special Committee on Standard Tonnage Basis for Refrigeration presented a report, already published in the January 1921 issue of Mechanical Engineering, defining the standard ton of refrigeration, the standard commercial ton and the rating of a refrigerating machine. The report was adopted.

The Joint Committee on Steel Roller Chains (with the Society of Automotive Engineers) presented standards for roller transmission chains and sprockets, which were adopted.

Fuel Session

Six papers were presented at the Fuel Session on Tuesday morning, namely: Recording Ash-Pit Loss from Chain-Grate Stokers, by E. G. Bailey; Boiler Tests with Pulverized Coal, by Henry Kreisinger and John Blizard; Limitations of Mechanical Stokers Utilizing Mid-West Coals, by E. H. Tenney; Capacity and Efficiency Limitations of Stokers Using Mid-West Coals, by John E. Wilson; Smoke and Its Relation to the General Health of the Community, by Dr. John Dill Robertson; and Latest Requirements of the City of Chicago in Furnace Design, with Special Reference to Hand-Fired Boilers and Limits of Each Design, by Frank Chambers. Joseph Harrington presided over the session.

The papers by Messrs. Kreisinger and Blizard and by Mr. Bailey were respectively printed in the May and June numbers of Mechanical Engineering; those by Messrs. Tenney and Wilson will appear in the August issue.

In the absence of Doctor Robertson, Commissioner of Health of Chicago, his assistant, Dr. Vernon Hill, spoke briefly on the importance of smoke-preventive measures in lowering the death rate from pneumonia and other acute respiratory diseases induced by the inhalation of dust-laden air. While admittedly an engineering problem, it had nevertheless been thought wisest in Chicago to entrust this work to the Department of Health.

Mr. Chambers' paper, which was read by R. H. Kuss, gave particulars of the requirements of the Chicago ordinance as regards fuel-burning equipment, together with data on draft losses through boilers, the rules employed in determining areas of stacks, height of furnace settings, etc.

Mr. Kreisinger supplemented his paper by particulars regarding the new Lakeside Plant of the Milwaukee Electric Railway and Light Company. This plant contains eight boilers, each with 13,060 sq. ft. of heating surface and burning about seven tons of coal per hour when operated at 300 per cent rating. In one 24.5-hr. test recently made at 136 per cent rating, the remarkably high thermal efficiencies of 85.6 and 90.2 per cent were respectively obtained for the boiler alone and for the boiler and economizer combined. In this test the CO_2 at the boiler uptake averaged 16 per cent, and in the gases leaving the economizer, 13.2 per cent. The gas temperatures were 432 deg. leaving the boiler, 392 deg entering the economizer, and 205 deg. leaving the economizer.

Frederick K. Scheffler[1] submitted a written discussion of the paper by Messrs. Kreisinger and Blizard, in which he said that the authors' tests confirmed other previously carried out and made it safe to state that a boiler and furnace efficiency of 80 per cent can be obtained with any kind of coal properly pulverized when burned in a plant designed to suit the operating loads and conditions.

H. G. Barnhurst[2] wrote that he believed the customary limitation of 85 per cent through a 200-mesh screen should be generally followed, but just how any particular coal should be prepared depended to a great extent on the amount of volatile and ash it contained. Granulation would not give really efficient results. Inherent moisture should not be confused with surface moisture, and the latter should be reduced to approximately 3 per cent. Coal should be dried before preparation—primarily to make transporting, storing and feeding easier.

Guildford Greig[3] wrote describing results obtained with a 400-hp. water-tube boiler at the Erie City Iron Works. The equipment was extremely simple, consisting of but a magnetic separator for removing tramp iron from coal before pulverizing, and a combined coal pulverizer and fan. The furnace had a water-cooled refractory lining, making it possible to burn coal with only 5 to 10 per cent of excess air. Neither drying equipment nor extreme fineness of grinding had been found necessary.

G. E. Pfisterer[4] in a written communication said that the tests were in the proper direction, for if the cost of drying and pulverizing could be reduced the field of usefulness of pulverized coal could be greatly extended. Since the heat absorption of the furnace coil mentioned in the paper was very large per square foot, it might be advisable to put it in circulation with the boiler.

Victor J. Azbe[5] said that Mr. Kreisinger had established a record of great economic importance in getting 90 per cent boiler efficiency. Now that this had been shown to be possible, an end should be made of the practice of operating boilers at between 50 and 60 per cent efficiency.

C. C. Trump[6] said that he had obtained an efficiency of 90 per cent with large boilers, underfeed stokers and economizers, and with at least 12 per cent CO_2 and with care in operation these figures might be exceeded. One advantage in burning fuel in suspension was the radiant quality of the flame, and part of the efficiency attained by burning fuel in pulverized form might be accounted for by the efficiency of heat absorption by direct radiation.

R. Sanford Riley[7] said that the results stated by Mr. Kreisinger set a new standard for possibilities in combustion. One limitation to the use of powdered fuel that might be mentioned was the high cost of the equipment as compared with that for stokers.

E. W. Wagenseil[8] called attention to the practically flat efficiency curve obtained in the Lakeside plant tests with pulverized coal for ratings from normal up to around 300 per cent, and said it was worth while noting that this was also possible with modern forced-draft types of stokers with a proper zone system of air control.

John A. Stevens[9] said that abroad the practice now was to preheat the combustion air, resulting in a gain of something like 2 per cent in the overall efficiency. A boiler efficiency of 90 per cent meant a kilowatt-hour on a pound of 14,000 B.t.u. coal, and this high value could be increased still more by preheating with steam drawn from the second or third stage of the turbine.

Mr. Kreisinger, in reply to queries, stated that in the effiicencies he had given no deductions were made for the economizers; and

[9] Cons. Engr., Lowell, Mass. Past Vice-Pres. Am.Soc.M.E.

that powdered coal was safe to handle if kept out of the boiler-room atmosphere. Replying to Mr. Stevens, he said that by preheating the atmospheric air fed to the furnace 280 deg. the boiler efficiency could be increased approximately 3 per cent.

Management Session

THE session of the Management Division, presided over by L. P. Alford, Chairman of the Division, was opened by the presentation of a report of the work of the Executive Committee during she first year of the organization of the Management Division. This report defined management as the art and science of preparing, organizing and directing human effort applied to control the forces and to utilize the materials of nature for the benefit of man. From this definition the following statement of the purpose or object of the Management Division was enunciated:

> Inasmuch as the problems of management are of the utmost complexity and difficulty, the Management Division of The American Society of Mechanical Engineers, in seeking to render disinterested service, therefore declares its purpose to be the formulation and declaration of the fundamentals of management, both regulative principles and accepted practice, and the dissemination of management knowledge. In working toward this object the Management Division can thus not only be of service to the other Professional Divisions of the Society, to the individual members of the Society and to all other societies of like aim, but also to all who are in responsible charge of human effort, and therefore through them of benefit to society at large.

The following activities of the Division in project were named: The standardization of management terminology, units of measurement, and methods of expression; the improvement and development of management education; the elimination of management wastes in industry; the elimination of unnecessary fatigue in industry and engineering; and lastly, management research. The report also listed the work of the Division in assisting local sections to conduct meetings during the past year. Two coöperative activities have been entered into, as follows: The joint committee on graphics with the Society of Industrial Engineers, the Taylor Society, and the American Statistical Association; and the joint committee on Management Terminology with the Industrial Relations Association of America, the National Association of Cost Accountants, the Society of Industrial Engineers, the American Institute of Accountants, and the Taylor Society.

Robert Thurston Kent presented a progress report of the Joint Committee of Management Terminology, of which F. E. Town is chairman. The report stated that the duties of the committee are the definition of management, the listing and defining of terms and phrases of management and the extension of the Dewey decimal system of classification to cover management literature. The Committee limited its field to management terminology applied (1) to production of basic materials for manufacture; (2) to manufacture, including products of public utilities; and (3) to construction of all kinds. In carrying out its work the Committee will request the submission of definitions of a tentative list of management terms from a great number of properly qualified persons and 98 colleges and universities. The definitions received will form the basis for the Committee's action in determining standards. Steps have been taken to form an advisory council composed of one representative from each of the large national trade or commercial organizations. In closing, Mr. Kent asked the membership of the several societies to assist by sending the chairman of the committee lists of management terms used in their shops.

A paper by W. C. Marshall, entitled Graphical Methods, was presented before the meeting. This paper will appear in a later issue of Mechanical Engineering. In a discussion of this paper, Morris L. Cooke pointed out that while the engineer is accustomed to the use of charts, drawings, tables, and blueprints, the general public is getting tired of these evidences of the engineer's technique. He stated it to be the duty of the engineers to make charts palatable and thereby greatly increase their effectiveness. L. W. Wallace further emphasized Mr. Cooke's remarks and stated his belief that education in graphics to catch and hold the eye and convey a lesson is a most important step in increasing public understanding of industrial matters.

In his paper on Industrial Waste, L. W. Wallace, Secretary of the American Engineering Council, presented some interesting facts resulting from the work of the Committee on Elimination of Waste in Industry. He pointed out that waste results from lack of planning, inadequate standards, faulty and uneconomic design, changes in style, and unfair practice; and predicted that the disclosures to be made in the report itself, which will be issued about September 1, will be interesting and vitally important. He gave a brief résumé of the work of the Committee from its appointment to the presentation of the report to the American Engineering Council on June 3, listing the problems solved, giving credit to the Committee members for their conscientious work, and outlining the final character of the waste report. He described the astonishment of the Committee upon finding after careful investigation that there was no known means or procedure for analyzing and evaluating waste, and pointed out the great value to management engineering of the method finally determined upon by the Waste Committee, the use and further development of which he commended to the Management Division. The difficulties experienced by the Committee because of the babel of management terms were explained by the speaker, who encouraged the Joint Committee on Management Terminology in their efforts.

In his discussion of Mr. Wallace's address, Morris L. Cooke pointed out the importance of the work done by the Committee in determining upon a method for waste evaluation and stated that the Management Division should utilize this method still further in the study of industry. Mr. Wallace emphasized the need of coöperation with other societies in putting this procedure to work.

Following Mr. Wallace's paper the meeting was turned over to a discussion of Mr. Cooke's paper on the Organization of an Engineering Society, presented at the Business Meeting of the Society on Monday, May 23. This paper, which was printed in the May issue, was prepared at the request of the Management Division and the discussion was held during the Management Session. This discussion will be abstracted in the August issue of Mechanical Engineering, which will also carry the proposed new constitution and by-laws of the Society, and should be given consideration by the membership of the Society in connection therewith.

First General Session

THE papers read at the General Session, Tuesday morning, Past-President D. S. Jacobus presiding, were Capacity Tests of Dry-Vacuum Pumps by the Low-Pressure Nozzle, by Snowden B. Redfield; and Report upon Efficiency Tests of a 30,000-Kw. Steam Turbine, by Herbert B. Reynolds. An abstract of Mr. Redfield's paper was printed in Mechanical Engineering for April; Mr. Reynolds' paper appears elsewhere in this issue. A brief résumé of the discussion follows:

Allen H. Blaisdell,[1] discussing the first paper, wrote that it seemed misleading to run tests on vacuum pumps using dry air rather than a mixture of air and vapor and then consider the results as indicating the actual capacity of the pumps.

Paul Diserens[2] said that the paper pointed out the ease with which a volumetric test of a vacuum pump or compressor might be made and emphasized the high degree of accuracy obtainable by the use of an orifice. He also called attention to the fact that the vacuum which a pump will develop on a closed suction gives a good indication of its volumetric efficiency throughout its entire working range. He then showed how closely calculated results and actual test results agree.

Wm. G. Christy[3] spoke of the length of the orifice beyond the curved mouth which the author had stated as ranging from 1/4 in. to 3/4 in. in length. He was under the impression that this should be as short as possible.

H. Boyd Brydon[4] said that a dry-vacuum pump should be tested under the conditions under which it was to operate, i.e., with moist rather than with dry air.

N. E. Taylor,[5] who presented the paper in the absence of Mr. Redfield, said that undoubtedly the moisture in the air influenced

[5] Engr., Ingersoll-Rand Co., Chicago, Ill. Jun. Am.Soc.M.E.

the results of the tests. The logical way to make the test, he said, would be to test the pump with dry air and then determine the effect of moisture.

The second paper was presented by H. Boyd Brydon in the absence of the author. The discussion was opened by the reading of the following communications here briefly abstracted.

O. H. Bathgate[6] noted that the water rates reported in the paper corresponded very closely to those obtained on another group of 30,000-kw. turbines reported by Messrs. Stott and Finlay, if proper allowance were made for difference in steam pressure and temperature. From this he concluded that it was hardly reasonable to expect any further increases in turbine efficiency for this size of unit unless obtained from units of radically different design.

W. S. Finlay, Jr.,[7] discussed certain ruling considerations such as the high price of New York real estate and the necessity and desirability of locating the turbines so as to secure their steam supply with proper distribution from the existing boiler plant. He stated the history back of the use of the spring supports for the condenser and many other details. He criticized the report for not being presented in metric as well as in English units.

Oscar F. Junggren[8] discussed the water-rate curve between 22,000 and 26,000 kw., saying that the secondary valve opened sooner than had been intended, resulting in a higher rate at this point.

Mr. Brydon asked a number of questions covering details of the installation and tests, which were answered by Mr. Junggren.

Frank R. Wheeler[9] said that he had used spring supports for condensers and had found them satisfactory. He had also used rubber expansion joints with copper thimbles to protect the rubber, with similar results. He called attention to the fact that about only half of the condenser surface was effective.

George A. Orrok[10] explained that condensers were designed for maximum conditions of steam and water temperatures, with the result that much of the time they were running at about half capacity. He also suggested hanging the condenser from the supports of the turbine so that a connection might be had between them without expansion joints.

T. E. Keating[11] mentioned the danger of overspeeding due to the admission of auxiliary exhaust steam unless the flow is under governor control. He asked for an explanation of the manner of determining the speed-curve corrections and the method of determining the heat transferred per hour in the condenser. He offered a tabulation of the heat-transfer coefficients as calculated from three of the tests and gave his assumptions in making the calculations.

Session on Education and Training

For the first time in the history of the Society a session was devoted to the subject of training for the industries at the Spring Meeting in Chicago. Dr. Ira N. Hollis, President of Worcester Polytechnic Institute and Past-President of the Society, called the meeting to order and introduced Dean Robert L. Sackett of Pennsylvania State College as presiding officer. In his opening remarks Dr. Hollis called attention to the importance of the problem of training for the industries as the phase of the present industrial crisis to which we have given least attention. The Society as a whole has no share in the establishment of schools and no responsibility for the training of men for the industries. Therefore the interest of the Society applies mainly to the dissemination of information to members and the public as to what is being done in remedying unsatisfactory conditions. Papers were presented by H. C. Smith, chairman of the Committee on Education of the National Metal Trades Association, on What the National Metal Trades Association is Doing and Intends To Do in Industrial Education; by Dugald D. Jackson, professor of electrical engineering, Massachusetts Institute of Technology, and Magnus W. Alexander, National Industrial Conference Board, New York, on The Requirements of Engineering Industries and the Education of Engineers; and by H. E. Miles on General Education and the Engineering Profession. The paper by Professor Jackson and Mr. Alexander appeared in the June issue of Mechanical Engineering. Those by Messrs. Smith and Miles will appear in the August issue.

Chicago Session

The Chicago Spring Meeting was noteworthy because of the policy of close coöperation carried out with the Western Society of Engineers. The session devoted to the consideration of the engineering problems of Chicago was given over to the city's transportation and terminal problems and the Chicago Terminal Committee of the Western Society presented its report at this session. F. K. Copeland, president of the Western Society of Engineers, was introduced as presiding officer by President Carman and the meeting was conducted throughout by that society. A considerable amount of valuable information was presented about the terminal problem in Chicago. The papers with their discussion will appear in the August issue of Mechanical Engineering.

Second General Session

Three papers were presented at the General Session, Wednesday morning, Manager C. Russ Richards presiding, namely: An Investigation of Oxy-Acetylene Welding and Cutting Blowpipes, by R. S. Johnston; Interpretation of Boiler-Water Analysis, by J. R. McDermet; and The Hydraucone Regainer, Its Development and Applications in Hydroelectric Power Plants, by W. M. White. Abstracts of the papers by Messrs. Johnson and McDermet appeared in Mechanical Engineering for May; Mr. White's paper was published in abridged form in the June issue. A very brief account of the discussion of these papers follows:

H. G. Knox[1] discusses some tests made on blowpipes at the Norfolk Navy Yard about a year ago. In these tests more attention was paid to the mechanical features and serviceability of the various blowpipes, and the interest was not so much in the theoretical gas consumption as in the general economics of field service. The blowpipes were examined from three viewpoints: design, performance and upkeep. Subdivisions under these headings were rated on a decimal basis, the weighted average representing the final merit of the blowpipe.

James W. Owens,[2] writing also on the above-mentioned tests, stated that the oxy-acetylene cutting tools were tested on metal up to 8 in. in thickness, this being considered the practical limit. Above 8 in. oxy-hydrogen should be used. In addition to the tests outlined by H. G. Knox, a six-month's service test was also made.

Alfred S. Kinsey[3] asked if the channel mentioned by the author and used under the welding specimens was for the purpose of preheating in order to increase the strength of the weld. The author replied that the channel was primarily used for convenience in bracing, but that it was noticeable in Table 6 that the second plate, which was subjected to greater preheating, was, in most cases, of higher tensile strength, which might indicate that preheating was valuable under certain conditions.

J. I. Banash[4] thought that the paper presented oxy-acetylene welding in too unfavorable a light. He brought out the importance of considering the personal element, and said that some of the criticisms were unjustified.

S. V. James[5] said that the safety of torches depended upon features of mechanical construction of far more importance than flashback, and thought that the author had overstressed this danger, which had never been of serious consequence in the industry.

Stuart Plumley[5a] thought the paper a serious indictment of the welding and cutting industry, and that the conclusions must have been based on a limited experience. The limit of depth of cut as set by the author was too low, while the tensile strengths reported were lower than those daily obtained in industry.

E. Wanamaker[5b] spoke of three primary features, economy of gas, quality of weld, and serviceability of the welding tool.

S. W. Miller[6] presented a written discussion of the paper in which he said that he considered the investigation of great value because it would do much to clear up erroneous and even foolish statements which had been made in the past. He pointed out that a tensile test on a non-uniform or non-homogeneous specimen must be interpreted with caution. It was too frequently assumed that the weld in a steel plate was of the same character as the plate itself. The weld, he pointed out, was a casting, of necessity more or less overoxidized, and metal in this condition had very different physical qualities from the original plate. These differences in quality he then discussed, and considered also the strengths of welds in general.

Mr. Johnston, in his closure, repeated the fact that the welders used in the tests were above the average and that none of the manufacturers of the blowpipes tested had complained of their skill. He hoped that the paper would not be considered as an indictment of the industry as it had been made as a scientific investigation to point out improvements which might be made.

D. S. Jacobus,[7] discussing the paper on The Interpretation of Boiler Water Analyses, spoke of the oxygen content of the water as affecting corrosion. Air can be removed from feedwater, he said, to the necessary extent by heating it in an open heater under atmospheric pressure at about 210 deg. fahr. Considerable economizer effect is thus lost due to the reduction of the temperature difference in the economizer, $1^1/_2$ per cent additional overall efficiency being secured, on an average, by allowing feedwater to enter the economizer at the lowest practical temperature rather than at 210 deg. fahr. aside from that which results through eliminating losses at the heater.

The author has not brought out the fact that he had been working on the development of the Elliott apparatus for the removal of air at ordinary feedwater temperatures so as to obtain the additional gain of $1^1/_2$ per cent in efficiency. Dr. Jacobus described the essential features of the apparatus.

Another reason for removing air from the feedwater was in order to increase the vacuum in the main condenser. This action may be obscured through leakage at the condenser.

G. E. Pfisterer[8] said that while the corrosion of cast-iron economizers due to oxygen was almost negligible, it was serious in economizers of steel. It was his impression that considerable experience might be gained from various installations of steel and cast-iron economizers now in use as regards the corrosive effects of oxygen and carbon dioxide. Comparisons would be difficult until figures regarding maintenance of steel economizers were available.

Discussion of Mr. White's Paper on the Hydraucone Regainer

The discussion of the paper on The Hydraucone Regainer was very voluminous and consumed so much time that an adjourned meeting was necessary in order to dispose of it. On account of limited space, it is possible to give only the briefest abstract of the discussion.

Geo. R. Shepard[9] surveyed the history of the tests which were made of draft tubes proposed by competing companies when the then Hydraulic Power Company was required by the Government in 1917 to proceed with the rapid development of additional power at Niagara Falls. The Hydraulic Power Company constructed a temporary laboratory with testing equipment substantially the same as shown in Fig. 19 of the author's paper and there were tested model draft tubes submitted by the competing companies. Some of the forms in addition to the hydraucone were (*a*) a straight draft tube as long as possible in the space available; (*b*) another form similar to this but flared partly at the end and fitted with a cone in the center; and (*c*) a curved draft tube very much flattened along the horizontal portion in an attempt to conform to the natural shape of the flow lines of the water. Finally an alternate design, Model "M," designed by Lewis F. Moody and of the symmetrically flared radial-discharge type was also adopted, and the hydraucone regainer used in the Allis-Chalmers units and the Model "M" in the others. The models were of 4 in. diameter of intake.

Tests of the models showed that Model "M" with the cone in the center, while not giving as high an efficiency as the model without the cone, seemed to have more uniform efficiency at greater or less velocities.

In addition to its efficiency, there is a practical advantage in the radial-discharge type of tube due to saving in excavation which is below tailrace water elevation and in most cases difficult and expensive.

Lewis F. Moody[10] denied the implication of the author that the draft tubes of Station No. 3 of the Niagara Falls Power Co., units 17 and 18, employ the hydraucone principle. These tubes, he said, were of the spreading-draft-tube type developed by him and were conceived along diametrically opposite lines to the tubes of the author. In this form of tube the water is received between two concentric surfaces of revolution in a direction tangent to both surfaces, and is guided along and not against the confining walls, being turned along curves having as large radii of curvature as can be conveniently adopted within the space restrictions of a plant, and deceleration of the flow is gradual and continuous at every part of the passage. The deceleration of the whirl components of velocity is made gradual and continuous by guiding all parts of the flow away from the axis along the central surface, and the deceleration of the meridian components is definitely controlled by the progressive enlargement of the annular cross-sectional area between the two surfaces according to a simple rule.

H. Birchard Taylor[11] wrote that the author confirmed his conclusions that in turbines of high specific speed, poor conditions of flow will exist in any form of draft tube which is not symmetrical with the axis of the turbine. In addition to this, he further stated that for best results in draft tubes the area through which the water flows from the runner to the tailrace should be enclosed between surfaces of revolution about the axis, and that both the axial and whirl components of velocity should be gradually and continuously decelerated. The author's tube did not meet this last requirement. The Moody tube, he pointed out, satisfied all three of the requirements.

Referring to Table 2 of the author's paper, the writer said that as an important consideration affecting the efficiency had been omitted, the assumptions given in columns 8 and 10 were extremely questionable and the results in column 12 incorrect.

In conclusion the writer stated that a free jet impinging on a flat plate or any other kind of plate involving in the jet pure streamline flow is a difficult condition to secure. It is a product of a laboratory and cannot be secured even there, except under ideal conditions, from a smooth orifice or nozzle attached to a reservoir. Although the author had demonstrated that by the use of a draft tube satisfying the conditions of symmetry it was possible to secure better results than in any form of draft tube which seriously violated these conditions, it must be clearly borne in mind that it is possible to design various types of draft tubes which satisfy these conditions without properly regaining all components of entering velocity. It was in the means for decelerating the velocity that the author and Mr. Moody were fundamentally apart.

F. Nagler[12] wrote that to his mind the remarkable feature of the hydraucone was found in the fact that the water can be turned abruptly at right angles in the conoidal chamber without appre-

ciable loss of efficiency. He was impressed by numerous instances of fairly close approach to the hydraucone principle but where the ultimate idea was not applied. Many tubes discharging against a flat plate have undoubtedly been investigated and numerous studies have been made in this country and abroad on the effect of a flat plate adjacent to the bottom of a vertical draft tube. These came under two heads:

a The work in question was done to overcome what was thought to be a positive disadvantage resulting from the proximity of the bottom of a tailrace;

b The work was performed to permit of some mechanical arrangement of cylindrical gate at the discharge of a wheel or in the attempt to apply a radial Boyden diffuser to some form of an axial-flow wheel.

The writer did not completely agree with the concluding paragraph of the paper. It could not be denied, of course, that any disturbance in the water at the exit end of a draft tube represents energy loss, but the extent of the loss was often overestimated.

L. F. Harza[12a] submitted a mathematical analysis of certain features of the author's paper and asked for additional data.

Arthur M. Greene, Jr.,[13] wrote that from Fig. 18 of the paper it seemed to him that the velocities recorded indicated a condition of disturbance, in that the various streams were moving at different velocities and were therefore moving one over the other and possibly permitting cross-flow.

Chester W. Larner[14] called attention to the fact that the author claimed to base his draft-tube design on the shape of a free jet impinging on a plate and that it was necessary to take into consideration the action of this free jet as it struck the plate if maximum recovery of velocity head was to be expected. This treatment was open to criticism for the following reasons:

1 A free jet presupposes straight-line flow, which does not occur in a draft tube;

2 The object of a draft tube is recovery of velocity head and there is no recovery of velocity head in a free jet, and

3 The author does not adhere to the free-jet principle in working out his own designs.

George F. Lovett,[15] who had been in direct charge of ten installations of the hydraucone regainer, wrote that it had been used in order to avoid the excavation of great amounts of ledge. The efficiency of the units had never been determined but their output had exceeded expectations.

Edward W. Burbank[16] wrote that as the design of the hydraucone can be changed as to its radius and as to volume of its conoidal chamber, the latter principally by placing cones of various sizes at the center of the bottom plate, it was not difficult to see that certain recently constructed regainers are in reality a variation of the hydraucone.

Arnold Pfau[17] wrote that the hydraucone regainer accomplished all that it should, namely—

1 Transforming the static suction head into pressure;

2 Transforming the kinetic energy of the discharging water into pressure, and

3 Transforming into actual head such energies as are latent in the disturbances.

Mr. Pfau added orally that he had found when in Europe recently that the turbine manufacturers there had not paid sufficient attention to the draft tube. American engineers, however, had fully realized its importance and had gone into its development far beyond those of other countries.

Joseph J. Ring,[18] writing of the research done on draft tubes and the development of the hydraucone regainer, said that the natural conclusion was that by using the hydraucone regainer with a runner of almost any specific-speed results could be obtained in the commercial power house as good as the best obtained at the Holyoke Testing Flume with the best possible testing equipment, without excessive excavation or prohibitive cost in the power house or in the hydraulic equipment used.

J. R. James[19] pointed out that the reduction of the depth of excavation was an important feature of the hydraucone regainer. He also suggested that the principle might be applied in steam plants in handling the water used in condensing. Water starting from the intake canal, passing up through the pump and through the condenser tubes and then dropping into the tailrace was in reality an inverted siphon. Therefore any method which would change velocity head into pressure head when the water enters the tailrace would help out the circulating pump to just that extent.

In the oral discussion Gardner S. Williams[20] referred to investigations he had made at Detroit and at the Cornell University laboratory regarding the flow of water and losses to pipe curvature. In 1899–1901 he had supervised tests of the hydraulic machinery of the Lake Shore Power Co. then being installed at Sault Ste. Marie and had conducted what was probably the most extensive investigation into the performance of water wheels attempted up to that time. After extended tests on a pair of wheels mounted on a single shaft and discharging horizontally in opposite directions, which was accepted practice in all low-head installations at that time, he decided to test the individual wheels with a vertical setting—something that had not hitherto been done—and the results showed a gain of 2 per cent in efficiency. He therefore felt a pardonable pride in having been the originator of the vertical setting for low-head installations. The curved draft tubes he had employed there were not very different from what had been recognized as standard elbow draft tubes for a number of years back. Along in 1912–1914 he had had an opportunity of designing a two-unit plant—the Argo Plant mentioned by the author—for a head of about 14 ft., and the draft tubes were designed by him following out his earlier investigations of the variation of velocity as water passes around a curve in a closed pipe. He had reason to suppose that the results obtained in testing that plant had made it possible for the author to carry out the experiments that had been described in the paper.

Later, in another plant, he had designed a draft tube in which four steel blades or fins projected about 8 in. beyond the wall of the draft tube, which checked the whirl of the water to a considerable degree. He felt entirely warranted in saying that for moderate heads it was possible to design an elbow draft tube that would give as high an efficiency as had yet been obtained by any other device. He did not wish to be understood, however, as saying that that was the best thing to do, the most economical or the most desirable, because it depended altogether on the conditions of the installation. The hydraucone called for a greater width than was required in the curved type of draft tube, and it was a matter of width of foundation versus depth. Conditions might be such that width would be cheaper. Generally, however, he thought that width would be less expensive, and therefore practical men would probably use the hydraucone or some similar device in the majority of cases.

C. B. Spellman[21] told of work he had done in redesigning a large, noisy centrifugal pump in which he had employed the Lorenz theory, one principal point of which was that in a right-angled bend the inner radius must be larger than the outer, which latter might even be a sharp angle. From the results of his observations in this work he believed that, referring to Fig. 18, the cone could be omitted and a sharp turn employed at the center where the velocity was very low and the pressure high.

The author in closing said that Mr. Taylor's point regarding one of the tables in the paper might be well taken; what he said regarding the whirl was true. Mr. Shepard's presentation was an unbiased statement of the facts. Mr. Moody had undoubtedly thought out and worked out his tube independently, but he had tested an identical one four years before. Fig. 18 of the paper had been developed to disprove a statement in Church's "Me-

chanics" to the effect that the formula $v^2 = 2gh$ is applicable to the pitot tube. He then showed several slides and concluded by saying that it should be borne in mind that the discussion was not on the relative merits of the hydraucone as compared with other devices. Competitors must and should have something of the kind, and the fact that 93 per cent efficiency had been obtained on the water wheel with the hydraucone and with another device showed that they were substantially the same thing. He would reserve extended comment until he had had sufficient opportunity to consider carefully the various discussions that had been submitted.

Power Test Codes Session

THIS session, held on Wednesday morning, Past Vice-President F. R. Low presiding, was a public hearing called for the purpose of discussing the proposed A.S.M.E. power test codes on General Instructions, Reciprocating Steam Engines, and Evaporating Apparatus. The first two codes were adopted with such slight verbal changes as the Committee might find were necessary to make them consistent with themselves and with other codes. The third code was referred back to the individual committee having it in charge for consideration at a conference to be held later with a similar committee of the American Institute of Chemical Engineers.

Railroad Session

THREE papers were presented and discussed at the Railroad Session on Thursday morning, namely: Advantages of Large Freight Locomotives, Particularly the 2-10-2 Type, by Albert F. Stuebing; The Design of Large Locomotives, by M. H. Haig; and The Necessity for Improvement in Design and Operation of Present-Day Locomotives, by H. W. Snyder. Mr. Haig's paper was printed in the May MECHANICAL ENGINEERING; the papers by Messrs. Stuebing and Snyder appear in this issue. In the absence of W. H. Winterrowd,[1] who had been selected as Chairman, Wm. L. Bean[2] presided.

In discussing Mr. Stuebing's paper, A. W. Bruce[3] wrote that it was practically impossible to compare engine maintenance costs on different roads because of the varying methods of accounting employed. It would be advisable, therefore, to adopt a uniform system which would also include electric installations.

O. C. Cromwell[4] said that in mountainous country the tunnel clearances made it necessary in designing heavy-powered locomotives to use limited bearing areas that contributed to increased cost of maintenance and kept down size of boilers. Probably more coal was burned because of lack of proper lubrication of cylinders than was wasted in any other direction. Further, machining of parts was not given the attention it should and formerly did receive.

P. R. Duffy[5] said that on eastern roads the Mallet and Mikado type engines did not appear to have as large tenders as they should have. Experience on his road for 16-hr. turn-about service had shown that the long, low tender carrying 15,000 gal. of water and 18 tons of coal was the most suitable.

Discussion of Mr. Haig's Paper on the Design of Large Locomotives

Mr. Haig's paper was also discussed by Mr. Bruce, who wrote that locomotives should be designed particularly for the work to be performed and then used for that class of work. Failures too often occurred from faulty pipe connections, fittings, etc. Proper maintenance of shoes and wedges, boxes and rods, etc., would go further toward keeping engines in service than anything else. Floating bearings if properly lubricated would give good service on main pins for main and side rods. Fireboxes should have crown and sides in one piece where possible. It might be well to consider cutting away the front part of the cab on large engines where no front door is obtainable to provide accessibility to the firebox staybolts.

Referring to the same paper, R. W. Brown[6] wrote that the New York Central had experienced more difficulty with cracks in spokes between the crankpin hub and the rim than between the hub and counterbalance. This difficulty was one for the steel foundries to remedy. There was a question whether the union link connected to the crosshead pin was as satisfactory as the long combination lever. Records of his road showed many breakages of piston rods just outside of the crosshead fit, as well as through the metal of the keyway. Rods should not have sharp corners or shoulders at the crosshead end. Cored pockets should be provided in braces where they bear against frames or other parts, so that when bolted together a full bearing area will be provided. To avoid cracking the shell, the New York Central uses a wearing plate around the boiler upon which the boiler brace angles can rest without rivets or other fastenings.

W. E. Symons[7] wrote that defects in steel castings for crossheads and other parts, shrinkage cracks, etc., could be detected by first immersing the part in benzine or kerosene, and then, after thoroughly wiping it, applying a coat of white paint or whitewash, following which the defects would be made apparent. Crosshead keys should not be driven home until given a preliminary test drive by a foreman and certified to over his signature. Forced feed for lubrication of cylinders and valves should be considered in view of the long life of packing rings in superheated-engine cylinders so equipped. It might be well to undertake an investigation to determine the relative values of grease and oil as locomotive lubricants.

C. J. Mellin[8] wrote that the Laird crosshead was suitable for slow-speed engines, but it had been almost entirely superseded by the alligator type. The introduction of the Walschaerts gear had made it possible to satisfactorily brace frames, but the design in Mr. Haig's paper seemed to him somewhat lacking in tram bracing for so large an engine.

J. G. Blunt,[9] in a written discussion, suggested that axles, boxes and bearings be standardized for the engine truck as they have been for the tender. Draw-pin bearings, center plates, side bearings and other working parts would respond surprisingly if supplied with lubricant, thus increasing hauling capacity and reducing maintenance. A frame to best resist combined stresses should follow as closely as possible the lines of a tube. It would be well to consider making the water column of steel tubing and placing all live steam pipes outside the cab.

J. E. Muhlfeld[10] wrote it was of the utmost importance to reduce weights of all reciprocating parts and that exceedingly large freight locomotives should be designed so that piston thrusts and stresses and the reciprocating weights will be distributed rather than centralized in order that excessive total rail pressures will not be produced by any pair of drivers. Locomotives should be able to double their present daily mileages. Certain means and methods that would increase locomotive starting power and hauling capacity and promote fuel economies without any considerable outlay were: Reduction of abnormal factors of adhesion by increasing working steam pressures from 5 to 20 lb.; increase in superheat; application of arched tubes in fireboxes; revision of locomotive ratings in order to utilize the increased capacity provided by the foregoing changes; distribution of locomotives over divisions and districts so as to insure maximum percentage of gross ton-miles hauled to locomotive rating ton-miles; purchase of most suitable materials for renewals and repairs; first-class enginehouse maintenance, packings, boilers, superheater, draft appliances, arches, etc.; establishment of adequate and effective central and field supervision.

F. E. Cardullo[11], who opened the oral discussion, said he felt that the developments in other lines of engineering had been such as to seriously raise the question of whether the design of locomotives ought not to be radically changed. The matter of condensation should be considered, for the arguments of 15 or 20 years ago no longer held. Radical designs should be put under way and tested to see if further advantages could not be had through rearrangement of some of the most important parts, counterbalancing, etc.

C. C. Trump[12] asked what the objections were to water-tube boilers and increasing the number of cylinders, and whether they were sufficient to offset the advantages they would give; and whether the advantages due to longer divisions and runs were sufficient to justify the use of superheaters, economizers, heaters, condensers and new methods of firing fuel.

H. Wade Hibbard[13] advocated the greatest possible rigidity in the frame, which he thought should be of box section throughout and all one steel casting. Castings of similar shape were now being successfully made.

O. C. Cromwell[4] said that if the steel castings used in locomotives were properly heat-treated their strength and durability would be increased and internal stresses largely eliminated, resulting in considerably lower maintenance charges. The location of cross-braces and brake rigging and the spring arrangement made it difficult to design a box-section frame. Broken frames could be largely reduced in number if the pedestal binders were kept tight and in place. The feet of the cross-braces should extend even further along the length of the frame than proposed by Mr. Haig in order to get more bolting in the frame to secure the casting.

E. B. Katte[14] said that he understood frames could be cast in steel integrally—the two sides cast with cross-transoms—and that in new locomotives constructed for the Paris-Orleans Railway of France these will be supplied.

Mr. Haig, in closing the discussion, said that the objection to additional cylinders was that they increased the cost of maintenance. The fire-tube type of boiler had been continued in locomotive service because it had been found to meet the conditions in a most practicable manner. With water-tube boilers wash plugs would be required at each end of each tube, the removing and replacing of which would add to the expense and would make it more difficult to clean the tubes. One-piece box-section frames had already been cast, but he did not know of any such frame actually having been applied to a locomotive. The leading objection to their use was the lack of facilities in the repair shops to care for them. The reinforcing features mentioned in the paper in connection with cylinders were intended to prevent their breaking when the heads were knocked out.

Discussion of Mr. Snyder's Paper on the Necessity for Improvement in Design and Operation of Present-Day Locomotives

A. W. Bruce[3] submitted a written discussion in which he said that the so-called floating bushing had been used on heavy-power engines on the main pin for both main and side rods, and when properly lubricated this loose bushing gave good satisfaction. The use of special steel for light parts, while desirable, was questionable until assurance could be had that the same steel would be carried in stock and used for replace parts.

H. B. Oatley[15] wrote that probably less attention had been paid to the more economic production of front-end draft than to any other detail connected with locomotive design; and that intensive work along this line was eminently desirable. There seemed to be no reason why 2 $^1/_4$-in. boiler tubes should be the upper limit in practical use. Long, small-diameter tubes unduly increased the resistance to flow of gases and would nullify to some extent the evaporative capacity unless the front-end draft was greatly increased. He had for several years advocated using 2-in. tubes when the length was from 15 to 17 ft. and up to 2$^3/_4$-in. for 30 to 33-ft. lengths, the shorter lengths being for soft coal and the longer for anthracite, oil and pulverized fuel. Domes had been gradually growing smaller and smaller. The absence of a dome however did not mean that practically dry steam could not be delivered to the superheater proper, but that the throttle, superheater (if any), dry pipe, etc., must be so arranged as to take care of the conditions. With long boilers on grades the rolling and surging would often cause slugs of water to splash up into the dome and pass to the superheater where they would deposit scale and produce deterioration.

C. J. Mellin[8] wrote that in regard to the matter of counterbalancing, the best method available appeared to be to use three cylinders and a single internal crank on the driving axle, which was a simple construction and provided room for parts of ample strength and bearings of ample size. While not giving as good a balancing effect as four cylinders, the method had the greater advantage of affording a better turning effect than any other means that might be suggested.

J. E. Muhlfeld[10] wrote that practically all of the 65,000 locomotives in the United States today were primarily improved enlargements and rearrangements of Stephenson's pioneer "Rocket," built in 1829. To improve their performance and efficiencies one of the simplest and most expedient means was to increase the boiler pressure and thus reduce the factor of adhesion. Superheaters, brick arches, feed heaters, etc., would increase sustained horsepower and promote fuel economy, but they did not materially affect the true capacity value of the locomotive, which was its starting power. With existing driving-wheel load limitations there was no reason for the factor of adhesion in freight locomotives to exceed 4 or 4.1 as a maximum when the limiting friction for dry sanded rail would allow a factor of 3 and for dry rail 4. Due to improper gas-area ratios, too few elements, or location of the superheater element rear return bends too far from the firebox flue sheet, many locomotives were being run with 50 to 100 deg. less superheat then would otherwise be obtainable. The use of 350 lb. steam pressure and 300 deg. superheat together with a more efficient boiler, improved combustion, better steam distribution and utilization of waste heat, would put the steam locomotive in a class by itself as the most effective and economical self-contained mobile power plant for the movement of fast and heavy rail tonnage.

Max Toltz[16] said that the water-tube boiler had been used by the French since 1903, particularly in Algeria They were now used on ships where in heavy seas the foundations similarly lacked rigidity. The simple engine was to be preferred to the compound, but steam pressures should be increased and superheaters employed.

W. E. Woodward[17] said that 20 years ago 70 hp. developed per five tons of locomotive weight was good practice. Now, however, 100 hp. for the same weight was common. The 3500-hp. engine at present used to pull fast, heavy trains weighed about 350,000 lb. If designed according to practice in 1900 to 1905 it would weigh at least 500,000 lb , could not be run on railroads, and would have a boiler so large that it could not be fired properly.

C. T. Ripley[18] thought that in future development work on the locomotive, the manufacturers, railroads, members of the mechanical societies and the universities with their faculties and equipment should be brought together, for their coöperative work would surely produce results quickly and at much lower costs.

In closing the discussion Mr. Snyder said that from his viewpoint the most economical railroad operation consisted in hauling the largest load possible. Capacity should be increased as it had been in marine practice, where no one would care to go back to the caravels of Columbus from the huge ocean liners of the present day.

Materials Handling Session

THE importance of machinery and its intelligent use in the building of roads furnished the topic for the first meeting session to be arranged and conducted by the Materials Handling Division. The subject was treated in the following papers which appeared in the June issue of MECHANICAL ENGINEERING: Planning and Organizing a Road Job for Mechanical Handling of Material, by C. D. Curtis; Road-Construction Plants, by B. H. Piepmeier; and Mechanical Needs in Highway Construction Methods, by R. C. Marshall, Jr. A lively discussion elicited from members and road-building contractors resulted in a successful session which laid the foundation for future coöperative gatherings between contractors and engineers.

In the written discussion William Ord[1] presented an analysis of the savings in investment and reduced overhead expenses when using one high-capacity plant instead of several smaller plants of the same total capacity as the large plant. He pointed out that with six months for actual mixing and six months for preparation twenty miles of 18-ft. road per year is a reasonable task for one plant if general conditions, such as labor, transportation and material supply, can be satisfactorily maintained.

William P. Blair[2] combatted the idea that standardization of road-improvement equipment is practical to a great degree in road-building machinery. He stated three elements of importance leading to the use of mechanical equipment, namely: reduced cost; elimination of rehandling; and proper scheduling so that no step will hinder the performance of any other portion of the organization or machinery.

In the oral discussion, E. H. Lichtenberg[3] emphasized the importance of standardization of equipment and methods of road building. He also spoke of the need for mechanical engineers to study carefully machine parts so that breakage might be eliminated as far as possible. Dean R. L. Sackett[4] compared the large road-building plant with the smaller plant, pointing out the ease of keeping up the supply of parts when a number of small similar machines were used. He also emphasized the need for protecting from grit bearings subjected to severe wear. Attention to such details of design should result in road machinery with a longer average life than four years.

Zenas Carter[5] quoted road builders of standing to the effect that proper drainage is by far the most important requirement for successful road building. Second, however, is the question of personnel, upon which he dwelt at some length. He also emphasized the need for awarding contracts to contractors who could do the work properly rather than to men who submitted the lowest bids. He stated the procedure in London, where the contractor who lays the road must keep it in condition for 15 or 20 years. Mr. Carter also advocated experimental highways in the building of which new mechanical devices might be tried out. O. B. Zimmerman[6] gave the results of his experience in the use of manufacturers' ratings in purchasing road-building equipment for the Government, where lack of a sound basis led to confusion and dissatisfaction. He suggested that the Materials Handling Division take up the standardization of ratings and parts for road-building equipment.

The afternoon was spent in the showing of moving pictures, the titles of the films being as follows: Modern Concrete Road Construction, with explanatory remarks by E. H. Lichtenberg; Methods and Machinery Used in Constructing and Maintaining Earth, Gravel, Macadam and Rigid-Surface Roads, with explanatory remarks by William Ord.

Forest Products Session

THE Forest Products Session was arranged by the organizing committee of the newly formed Forest Products Division. Robert B. Wolf, a member of this Committee and Vice-President of the Society, presided.

One paper, on the Paper Industry of America Dependent upon a Permanent Wood Supply, was presented by Hugh P. Baker, executive secretary of the American Paper and Pulp Association and formerly dean of the Forestry School at Syracuse University.

In his paper Dean Baker outlined the history of paper manufacture and showed the increase in the use of wood pulp for paper until today only 2 per cent of paper is made from pure rag stock. He spoke of the old methods of pulp grinding and pointed out that the chemical methods of reducing wood to pulp have been the basis for the rapid growth of the industry and a considerable price reduction.

Dean Baker listed the kinds of woods most desirable in the manufacture of pulp. The conifers are especially profitable because of the fiber length and ease of reduction to pulp. Hard woods have large possibilities in the paper industry.

Having shown how important a permanent wood supply is in the paper industry, Dean Baker stated that at the present time less than two-fifths of the timber in the original forests of 820 million acres is left for our industries and for constructive purposes. The traditional feeling on the part of the early settlers that the forests were a hindrance and a menace to their safety has logically developed the present attitude of indifference or opposition to forest conservation. Various estimates during the past 20 years have been made of the supplies of timber left. There are still fine forests of considerable extent, and with proper protection from fire these forest areas reproduce rapidly. Increased use of forest products makes it absolutely essential that forests be protected from fire and that progress be made in forest renewal.

The paper industry is interested in the stand of timber east of the Mississippi, for that is where the paper mills are. Of the 2215 billion board feet still standing, less than 900 billion are in this region. Of the wood taken out of the forests it is estimated that two to three per cent of the total quantity is used by the paper industry. Twenty-two per cent of the pulp used in the United States paper mills during 1920 was imported from Canada and Europe. Spruce is the most popular wood for pulp, 58 per cent of the total used being of this species.

The discussion of Dean Baker's paper centered around the utilization in the pulp mill of sawdust, shavings, sawings, short lengths, etc. Consensus of opinion seemed to be that because of the dirt always present, such waste, unless cleaned, which is an impossible process in the case of sawdust, is used with difficulty. Moreover sawdust packs, gets soggy, and therefore does not adapt itself to the process of paper making. The presence of knots in wood introduces an added difficulty. Waste wood can be rendered available only by very careful sorting. Furthermore all present were agreed that the economic utilization of wood waste was not so important an item as that of getting waste out of the way. In lumber-using factories it was therefore generally better to burn the waste, even though in some cases it might be necessary to install special apparatus for the purpose. A number of those present told of practices in the more economical use of wood waste which had considerably reduced the fuel bills of their factories. It was stated that sawed blocks of mixed woods, after having been thoroughly cleaned, might be used in the soda process of pulp making. The chairman pointed out that the largest waste in a paper mill is waste in the utilization of the intelligence of the workman, due primarily to lack of proper provisions for showing him the best methods and to lack of records so that intelligent work may be properly rewarded.

A resolution was presented to the meeting in which it was recommended to the Council that the Society go on record as in favor of a systematic forest policy promulgating definite plans by means of which, with the coöperation of public and private agencies, a prompt solution may be found for this extremely important national problem.

At the closing of the meeting the following executive committee of the Division was elected:

Group of A.S.M.E. Members at Rock Island Arsenal

Grant B. Shipley, president, Pittsburgh Wood Preserving Company, Pittsburgh, Pa.

Thomas D. Perry, vice-president and secretary, Grand Rapids Veneer Works, Grand Rapids, Mich.

Sern Madsen, mechanical engineer, Curtis Companies, Inc., Clinton, Iowa

Charles E. Paul, consulting engineer, National Lumber Manufacturers Association, Chicago, Ill.

Carle M. Bigelow, chief industrial engineer, Cooley & Marvin, Boston, Mass.

O. H. L. Wernicke, vice-president, Pensacola Tar & Turpentine Company, Gull Point, Fla.

Power Session

At THE Power Session, Thursday morning, Samuel Insull[1] presiding, two papers were presented: Location and Distribution of Central Station Power in the Middle West, by W. L. Abbott, and Future Power Development in the Middle West, by C. W. Place. Mr. Abbott's paper is printed elsewhere in this issue. Mr. Place's paper, which will appear later in Mechanical Engineering, dealt with certain phases of the question of power production and use. In it he outlined a system in which the fairly efficient steam power plants in the 100 odd cities of over 25,000 population in the 14 central states would be interconnected, not by heavy high-voltage lines, but by lines which would pick up the small town and village load to the point where its next larger neighbor would take its share; hydroelectric plants would be installed on the streams near the towns and villages, each with a small pondage; the steam stations would carry the steady continuous load above the maximum stream flow and the hydroelectric plants would automatically come on to carry the peaks. On the off-peak period the hydroelectric plants would restore the pondage and carry local load. The quickness with which the latter could get on the line (12 to 30 seconds) would enable the steam stations always to work at maximum efficiency. Mr. Place took occasion to urge engineers to use their power of straight thinking to assist the civic, political and financial interests in arriving at right conclusions.

In opening the discussion Chairman Insull pointed out that the great interest developed recently in the subject of the location and distribution of central-station power in the Middle West was undoubtedly due mainly to the taxation of transportation facilities during the war. It took that war to convince the country that concentration of production of energy was in the interests of the whole people. The superpower scheme as presented in the East was very good in itself, but he believed that if engineers would pay more attention to similar projects in their immediate localities they would accomplish more than by considering the matter as a general proposition. It was seldom that there were ample supplies of feed and condensing water where coal was produced economically. A proper location of power stations and economic tying up of existing facilities would relieve the railways of some of their burdens, hasten the day when their power would be furnished more economically than by steam locomotives, and afford an opportunity of supplying electrical energy to every hamlet and farm as cheaply as it was done in large cities.

W. E. Bryan[2] said that the United Railways of St. Louis used about half of the energy generated at the Keokuk hydroelectric plant. In order to insure continuity of supply, however, they felt it necessary to have installed in St. Louis considerably more steam-generating equipment than was needed to care for the loads day in and day out.

Geo. A. Orrok[3] said that the point had not yet been reached where an electric transmission line could be built that was proof against the direct stroke of lightning. It was therefore necessary to have practically a full steam reserve if dependence was to be placed on a long-distance line and where continuity of service was the desideratum.

As to the use of spare hydro power to pump water up to a storage reservoir to be used through a turbine and generator at the time of the peak load, this was practicable if a natural storage pond was available near by, but to build a reservoir of any considerable size would cost more than could be gotten out of it.

John A. Stevens[4] spoke of interconnection of stations in England, where under the rulings of the Electricity Commission it was allowable to draw on the less efficient stations only when their capacity was required. In Italy provision was made by the government for the protection of the investment in those stations in an interconnected system where the cost of producing energy was higher than in the others.

Chairman Inull in closing the discussion told of the development of interconnection in Illinois and neighboring states. Already there was practically a continuous system of distribution extending from Minneapolis southward to St. Louis and Louisville save for gaps totaling about 120 miles. The diversity of demand existing between city and country would go a long way toward providing a load factor that would amount practically to continuous use. No concern should be allowed to generate energy that would cost more than it could be bought for. He had advocated regulation for 25 years and believed that the various state utility commissions should be empowered to regulate the industry much more drastically than formerly along economic lines, for it was just as interstate in character as the railway and the telephone.

Aeronautic Meeting at McCook Field

The visit of the Society to the McCook Field Air Service Station on May 21 was something more than a sight-seeing pilgrimage to a point of engineering and patriotic interest. It was a plan instituted by the new Aeronautic Division of the Society to develop the interest of the membership, and the engineering profession in general, in the national aviation policy, both govern-

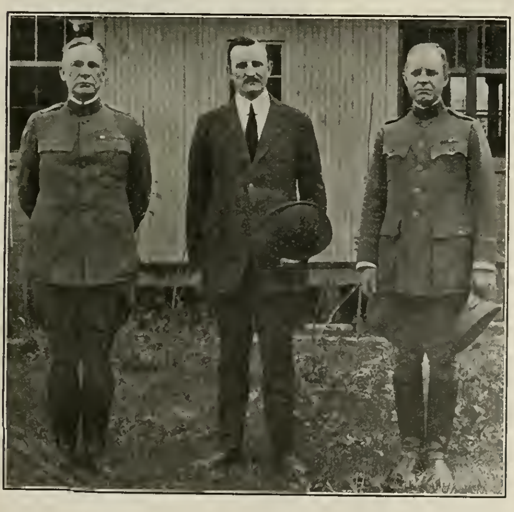
Airplane View of McCook Field

mental, through the Air Service, and commercial, which latter should be of especial concern to all of us.

The Air Service officers at Dayton, as well as their superiors in Washington, were successful in stimulating the engineers who participated in the trip to the realization that progress in the art from now on was to a large extent dependent upon their sympathy and support, and that if the United States wished to develop an efficient defense arm in the air, coöperation between governmental and industrial agencies should be developed as rapidly as possible.

The Society of Automotive Engineers, which has done so much valuable work in this field, participated in the visit. The S. A. E. members were on their way to their own spring convention at West Baden, Indiana, just as ours were to our Chicago convention. The registration at McCook Field was 203; twelve states were represented. There were of course large contingents from Dayton, Cincinnati, and Springfield, Ohio.



From left to right—Col. C. L'H. Ruggles, Chief of Technical Staff; E. S. Carman, President A.S.M.E.; and Lt-Col. Harry B. Jordan, Commanding Officer, Rock Island Arsenal.

The Air Service had prepared an elaborate program, which was carried out to the letter, with the result that ample time was available for all events.

The arrangements at the Field were in charge of Major Thurman H. Bane, Commanding Officer; Major George E. A. Hallett, Mr. Glenn Martin, and Mr. Joseph A. Steinmetz, chairman of the A.S.M.E. Aeronautic Division. The officers at the Field all assisted; of these Lieut. E. E. Aldrin is secretary of the Executive Committee of the Society's Aeronautic Division.

Distinguished visitors were Messrs. F. Handley-Page and Griffith Brewer of England, and Orville Wright and C. F. Kettering.

Promptly at ten in the morning the visitors assembled and Major Bane outlined the program of the day. The forenoon was given over to inspections of the materials laboratory, the shops, and the power-plant laboratory—all splendid examples of engineering practice embodying many features of interest.

A unique feature was the armament-testing laboratory, at which exhibitions of synchronized firing attracted much attention.

Then came an inspection of airplanes on the line—thirty-one machines in all, ranging alphabetically from Caproni to Thomas-Morse, and from bombers and pursuit to honeymoon express in type. Sixteen of these machines were flown.

Following a splendidly served lunch at the Field's cafeteria, there was a professional session in the Auditorium, with papers by E. H. Dix, S. D. Heron, Bayard Johnson, C. F. Taylor, Gerald P. Young, O. E. Marvel, G. W. Stevens, and A. O. Russell, all of the Air Service Station. The respective subjects were Aluminum Cylinder Castings; Air-Cooled Airplane Motors; Airplane Radiators; Carburetor Problem on Aircraft Engines; Color Camouflage; Radio Apparatus, Including Direction Finders; Aerial Photography; and Machine-Gun Synchronizers. These papers will be abstracted in a later issue of Mechanical Engineering. Chairman Steinmetz presided at the professional session.

In the evening the visitors and their ladies enjoyed dinner in the beautiful building of the Dayton Engineers' Club. Messrs. Kettering, Handley-Page, and Steinmetz were the speakers, and the trend of their remarks was the necessity for the development of commercial aviation. Mr. Handley-Page recounted the developments in Europe along this line, while Mr. Kettering urged the production of a reasonably priced commercial machine, without which the public could not be expected to take up flying.

The last event on the program was a military ball given by the officers of the Field and held at the Miami Hotel.

The thanks of the Society are due to all the officers of the Air Service who contributed to the success of the day at McCook, which was acknowledged by everyone as a pleasurable as well as a profitable opportunity to show our interest in the magnificent work the Air Service is doing.

Rock Island Excursion

About forty of those attending at the Chicago meeting went to Rock Island on Thursday night, joining with some sixty engineers from the Tri-Cities Section for the events at Rock Island and Davenport. They started with a trip of inspection through the Rock Island Arsenal where Col. Harry B. Jordan, Commanding Officer, conducted the party through the modern shops in which

SURVEY OF ENGINEERING PROGRESS

A Review of Attainment in Mechanical Engineering and Related Fields

First Motorship with Double-Acting Two-Stroke-Cycle Engines

By R. DREVES

THE present article is of interest not only as describing an important project in motorship construction but also as illustrating the German method of going about the job of solving technical problems where experiments on models are not feasible.

The years 1909 and 1910 were signalized by a rapid growth of interest in Diesel engines, owing to the expiration of the life of the original Diesel patents. At that time the Augsburg-Nuremberg Engine Co. and the Blohm & Voss Shipbuilding Co. in Hamburg jointly formed a research corporation to develop large oil engines for ship use, and, in particular, for use on warships. It was decided at that time that the Diesel engine best suitable for this purpose would be of the double-acting two-stroke-cycle type.

As the first step in this development it was decided to build comparatively small units so as to keep within bounds the cost of experimentation. At the same time, in order to test the engine not merely on the testing stand but under actual conditions of operation, the Blohm & Voss Co. decided to lay down in its yards for for its own account a double-screw experimental freighter to be equipped with double-acting two-stroke-cycle engines. The actual work started in 1910—the ship to have an overall length of 106 m. (347.6 ft.) and a deadweight of 3083 registered tons.

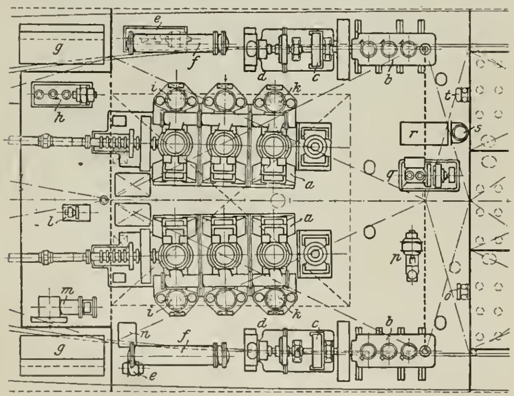

Fig. 1 Engine Room of the Motorship *Fritz*

The first three-cylinder unit could not be put into the ship because while on the test stand cracks appeared in the cylinders. Its engine was, however, used for experimental purposes and as a basis for the design of a new unit. This latter had working cylinders of 480 mm. (18.9 in.) bore by 710 mm. (27.9 in.) stroke, with an output at 120 r.p.m. of 830 s.hp. The fuel-injection compressor built as a three-stage unit was driven by a crank from the extension of the main crankshaft, an arrangement which since has become fairly universal. This compressor has bores of 510, 445 and 115 mm. (20, 17.4 and 4.55 in.) and a stroke of 350 mm. (13.75 in.).

The three scavenging pumps of 650 mm. (25.60 in.) bore and 500 mm. (19.6 in.) stroke were driven from the crossheads of the working cylinders, while the six-cylinder fuel pump of 11 mm. (0.43 in.) bore and 60 mm. (2.36 in.) stroke was driven by an eccentric from the camshaft.

Furthermore, the bilge pumps and fresh-water pumps for the piston cooling were driven by means of a rocking lever from the first and third cylinder.

In designing the engine the question of reliability was made paramount, while weight and cost of construction were secondary and even fuel consumption was treated as being subordinate to reliability. As regards weight, it was decided that the Diesel engine should weigh about as much as a steam engine of similar output. Because of this, not only the bearings but bedplates, foundations and other parts were made of unusually generous size. If it had been desirable to keep down the weight many parts

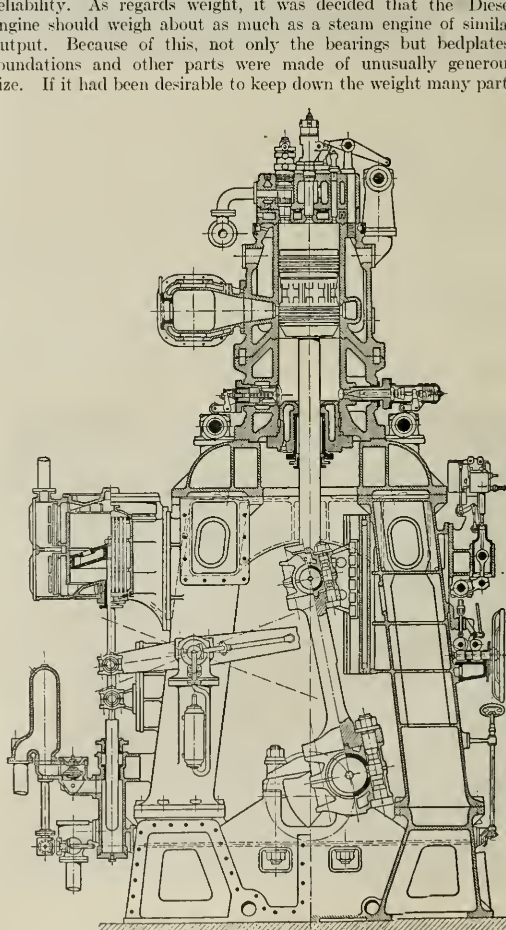

Fig. 2 Cross-Section of Main Double-Acting Two-Stroke-Cycle Diesel Engine

could have been made at least 50 per cent lighter. No effort was made to keep down the length of the engine since this was so small anyway that the size of the engine room was determined not by the dimensions of the engine but by the location of the auxiliary machinery, as may be seen from Fig. 1. This, for example, made it possible to design a crankshaft in the manner usual with marine engines, namely, in three parts with two bearings between each two crankshafts. This tended to make the loads on the bearings extremely light, which was further assisted by the fact that in

double-acting engines the variations of pressure on the bearings are more favorable, giving them a longer life than is the case with single-acting engines. As a result of this, it proved to be possible to operate the bearings just as in steam engines—without forced lubrication, and this, in its turn, permitted making the engines open-type and thoroughly accessible in all their parts, which was particularly desirable as it made it easy to inspect the stuffing boxes on the piston rods. It may be mentioned in this connection that during the entire period of very extensive series of tests these stuffing boxes have never given any trouble. Fig. 2 shows a cross-section of this engine.

The working cylinders are made up of two parts. At the bottom of the cylinder, which constitutes the upper part of the columns and reinforces it crosswise, is located the lower part of the double-acting working cylinder which is closed at the bottom by a special head.

In the upper head the valves are set in the usual manner and comprise one starting valve, one fuel-injection valve, two scavenging valves and one safety valve. In the lower cylinder head there are two fuel-injection valves, two scavenging valves, a starting valve and a safety valve.

The arrangement is such that the valves are easily accessible to the engine personnel and can be withdrawn in a very short time without disturbing any other part of the engine mechanism.

The starting valve is built as a balanced valve and is operated by compressed air. Fig. 3 shows the starting valve for the upper half of the double-acting cylinder. The valve opens with air admission to, and closes through air exhaust from, the air chamber over the distributing piston, the air being governed by means of the starting throttle. Each starting valve is equipped with two starting throttles located in the same housing, one being intended for forward and the other for reverse running of the engine. The needle of the fuel valve opens into the cylinder, but can be adjusted without trouble from the outside.

The working pistons are in two parts. The lower part is attached

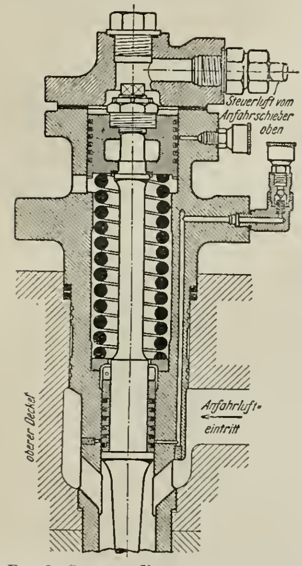

Fig. 3 Starting Valve of the Upper Part of the Cylinder of the Double-Acting Two-Stroke-Cycle Engine

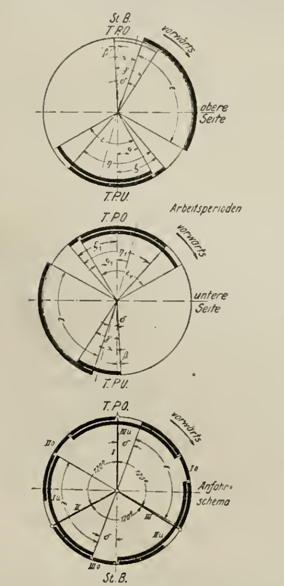

Fig. 4 Valve Diagrams of the Double-Acting Two-Stroke-Cycle Diesel Engine

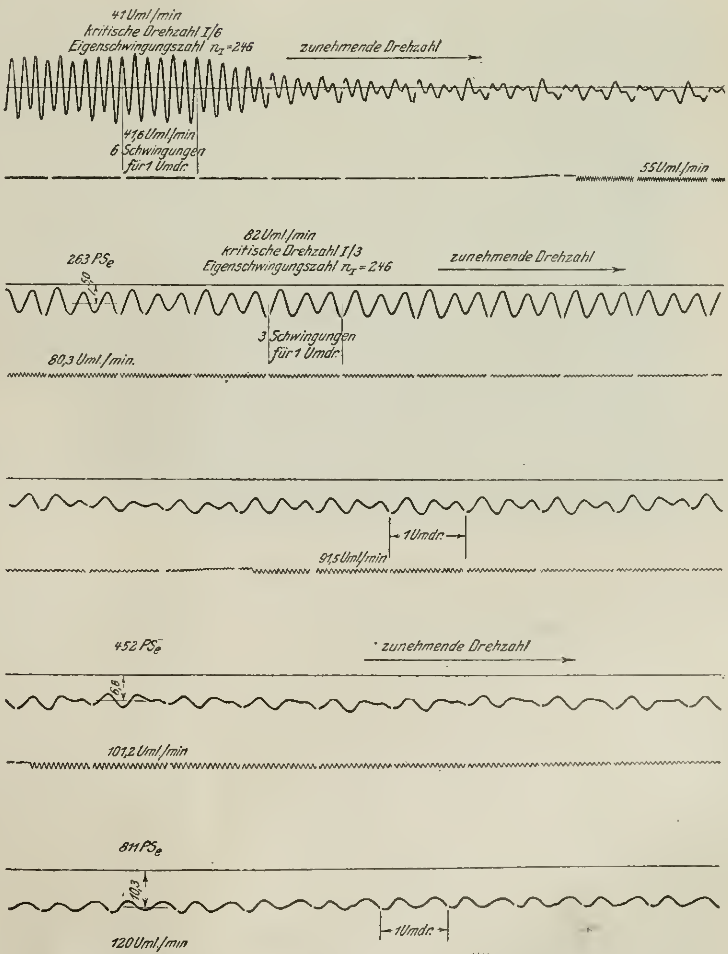

Fig. 5 Torsion Diagrams of the Reconstructed Diesel Engine Taken by Means of a Frahm Torsion Indicator

to the piston rod and carries a cast-iron upper section from which it may be separated by sheet-iron disks, the volume of the combustion space varying with the number used. The piston in each half of the cylinder is equipped with five cast-iron rings held so as to make their rotation impossible.

The valves are operated by cams. The upper valve set is operated by means of a single camshaft, while in the lower set there are two camshafts—one in front and the other back of the cylinders, all three camshafts being driven by gear wheels in the same manner as other Diesel engines built by the company, generally referred to as "MAN," its German name being the Maschinenfabrik Augsburg-Nürnberg.

The engines were very extensively tested both on the testing stand and in the ship. Before the first of the two engines was put into the ship it was subjected to a test equivalent to six days of uninterrupted travel, then 12 hr. of maneuvering, 3 hr. of reverse

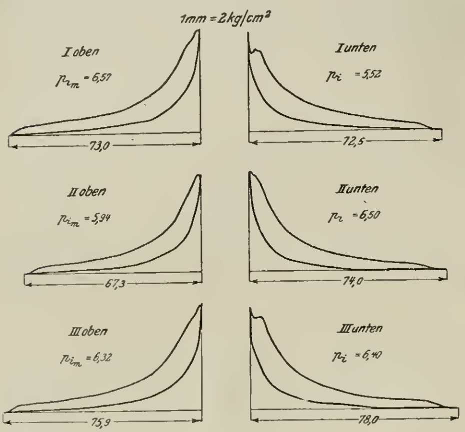

Fig. 6 Indicator Diagrams Taken During the Second Trial Run

running, and 4 hr. of slow-speed travel. The second engine was tested in the same manner. (It is not quite clear, however, how the first engine was tested in this manner *before* it was installed on shipboard.)

The fuel consumption proved to be 225 grams (0.48 lb.) per hp-hr. with an overall efficiency of 72 per cent. The mechanical efficiency, taking into consideration the indicated output of the scavenging pump and compressor, was 89 per cent. It would be difficult to expect anything better from a comparatively small engine. When the engine was tested on shipboard important disturbances appeared through the rise of oscillatory motions with amplitudes which previous experience did not lead one to look forward to. In fact, certain speeds of rotation could not be employed at all without endangering the entire installation and could be obtained only with unusually heavy fuel consumption. The conditions were made still worse through the fact that the cruising speed of 120 r.p.m. happened to be within the critical range of the engine. Important alterations had to be made in order to get away from this situation.

After the engine was rebuilt measurements were made by means of a Frahm torsion indicator developed in the meantime and some of the torsion diagrams are shown in Fig. 5. From these can be seen the uniformity of running at the higher speeds. At 82 r.p.m. and 41 r.p.m. are located the two critical speeds of the third and sixth order. Further measurements were carried out on submarine engines both on the testing stand and on board a submarine, and data collected in this way are now used by Blohm & Voss in the design of their commercial heavy-oil engines. So that while it is still impossible to compute the oscillatory disturbances which may arise at certain higher speeds, sufficient data are available to make it possible to design engines in such a manner as to keep on the safe side.

The first experimental run on the motorship *Fritz* was undertaken on the River Elbe in May 1915, lasted 8 hr. and was free from any trouble. The fuel consumption proved to be 160 grams per i.hp-hr. (0.35 lb.) with an average output of 1093 i.hp.

The next test run could not be undertaken until September 1919. During these test runs the diagrams of Fig. 6 were taken showing the operation of the upper and lower ends of the various double-acting cylinders.

In accordance with the Peace Treaty the motorship was surrendered to England. It is of interest to note that the firm of Blohm & Voss called the attention of the British Government to the fact that the ship was of a merely experimental character and that at least a few more sea trips ought to be undertaken to determine the reliability of the various apparatus. The firm therefore made a proposal to the British Government that a few more runs should be undertaken in the Baltic. The British Government accepted this proposition and in November 1919 an acceptance run was undertaken. The ship encountered very heavy weather but reached England safely.

Since that date the two German concerns working in coöperation have undertaken and executed the construction of marine engines of the type described here, but of very much greater dimensions. Centrifugal Casting Processes

HUME CENTRIFUGALLY MADE CONCRETE PIPE

DESCRIPTION of a process for the manufacture of concrete pipe by centrifugal deposition as carried out by a company in South Africa. The pipe is reinforced with steel and the first step in its manufacture is the preparation of the reinforcement. As the plant is located not far from the gold-mining district of the Witwatersrand, it is able to make use of the discarded mine-haulage cables for this purpose.

The cables are delivered at the pipe works in coils and are first degreased, which is necessary as cement will not adhere to any material that has a greasy surface. The grease is burnt out in a wood fire, the wire being somewhat annealed at the same time.

After a coil has cooled down it is unraveled with the help of specially designed machines. This is followed by spooling the wire, the spools being then transferred to the machine on which the reinforcement cylinders are made.

A spool of wire is placed on a spindle, set vertically, and fixed, a few feet from the machine. The end of the wire is drawn forward and threaded through a series of three pulleys on a traveling feeder, these pulleys serving to keep the wire tight. The feeder itself is part of the reinforcement machine, along the base of which it is drawn by chains in a direction parallel with the cage core.

The reinforcement or "cage" is built on a round horizontal core consisting of four radially collapsible sections.

The molds are two-piece cylinders made of galvanized iron and are greased inside to prevent the cement from adhering. The reinforcement is then inserted and the end caps bolted in position. These end caps are broad, flat rings, the inside diameter of which is the inside diameter of the pipe to be made, the desired thickness of the pipe wall being exactly secured by the use of rings or end caps of the proper dimensions.

The pipe-making machines each make six pipes in one operation, the duration of which may be anywhere from 12 to 20 min. according to the size of the pipe.

In making the concrete for low-pressure pipe, Pretoria cement is used with sand and specially selected $^1/_4$ to $^1/_2$-in. grit in the proportion of 2 to 2 to 1; for high-pressure pipes sand and cement are used in the proportion of 2 to 1. The material is prepared in rotary

into the mold. When the molds have received sufficient concrete the speed of the machine is increased. This speed varies with the size of the pipe and, for instance, for a 4-in. pipe is 360 r.p.m., while for a 6-ft. pipe it is 48 r.p.m.

One of the important features about the Hume pipe is the great denseness of the material. The following tests have been made to prove this. An ordinary 12-in. mold without reinforcement was filled with concrete and rammed in by hand as tightly as it would go. In other words, the same process was followed as one might use to make a solid concrete column. The mold was then placed in the machine and rotated for a period at the speed required for the making of an ordinary Hume pipe. The mass was then examined and was found to have developed itself into a pipe with an internal diameter of $3^1/_2$ in., which would mean that the 12-in. column as originally made had a volume of air-filled spaces between particles equivalent to a pipe $3^1/_2$ in. in diameter and that by the centrifugal action this was packed solid.

The pipe has also a rather unusual joint. The end of each pipe is so molded that instead of a flat surface a groove of a peculiar shape is produced, this groove being such that its deepest portion lies toward the inner periphery of the pipe, while it becomes shallower as it reaches the outside periphery. When two pipes are brought together their edges enclose a cone-shaped space, the apex of the cone being toward the outside of the pipe, and this space is filled by the pipe layer with a special plastic compound.

A sleeve of concrete also goes over the joint and its inside diameter is a little larger than the outside diameter of the pipes. The annular space thus formed is filled with a mixture of sand and cement, which is calked or rammed into position exactly as lead is used for jointing iron and steel pipes. The practical effect of this system of jointing is that the greater the pressure of water in the pipes, the more resistant to leakage becomes the joint.

It is claimed that the Hume pipe never bursts and that when the pressure is increased beyond a certain point the pipe merely begins to "weep." If the pressure is further increased sprays of water appear, but there is no burst; moreover, when the water pressure is reduced to normal the pipe is just as efficient as it was before. In other words, the strain does not cause any deterioration. (*The South African Journal of Industries*, vol. 4, no. 3, March-April 1921, pp. 224–235, illustrated, *dA*)

the works of the George C. Clark Metal Products Company, Detroit.

The process appears to be one which requires a high grade of skill and knowledge at practically every stage. Beginning with the handling of the metal, it would appear that positive methods must be employed that will permit the band to be cast at the most desirable temperature, as otherwise the physical properties of the compound will not be right.

The metal is cast in down-draft melting furnaces of 3000 lb. capacity each, and from the furnaces is poured into ladles of a capacity sufficient for three bands. It is hauled to the casting room by means of an overhead trolley system and extra precaution is taken that the metal does not oxidize while on its way there.

The casting machine is shown in Fig. 1. Its principal parts are the die and die holder, the movable spout and the metal-pouring attachment. The holder is made of plain carbon-steel wire; the die or liner is a specially heat-treated forging. A hinged cover plate of the same diameter as the holder and having an opening large enough to accommodate the pouring spout is made to open and close on the side of the die and holder. It is said that the life of a liner is such that about 250 bands may be cast before it is burned out and replaced.

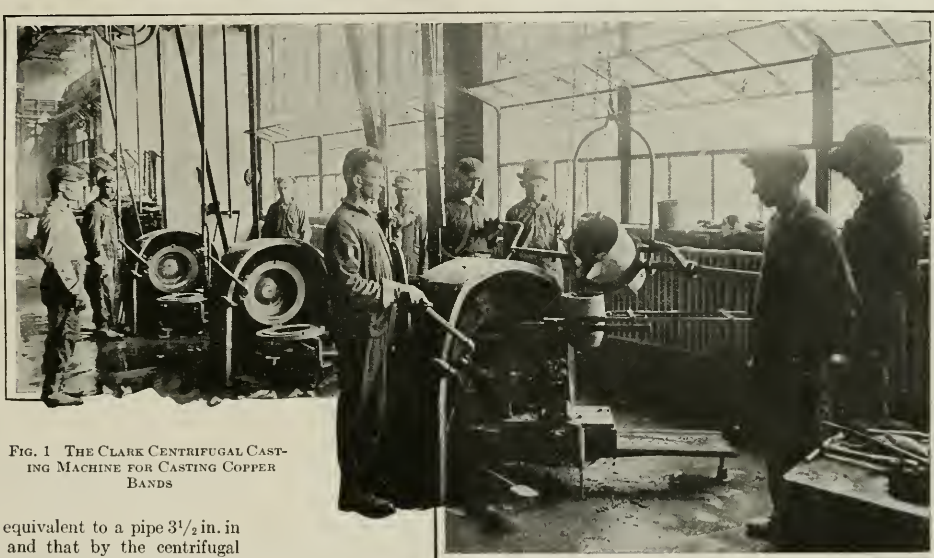

Fig. 1 The Clark Centrifugal Casting Machine for Casting Copper Bands

It is obvious that all revolving parts must be in absolute balance, as otherwise the band will not come out true. The metal is poured through the spout so arranged that it can move in and out of the die. Pouring is done by tilting the small crucible in the machine so that the metal will flow through the spout into the die. While the machine is still in motion the spout and crucible are pulled back out of the way, and when the band shows the desired color for annealing, a stream of water is turned on the band. After the band has sufficiently solidified and has received the proper annealing, the water pipe is taken back out of the way, the cover plate is unscrewed and the band removed from the die. After the band is cast it is necessary to keep the lip of the pouring spout clean as a certain amount of metal clings to its side and has to be removed by hand with a chisel. The bands themselves are then machined.

It is stated that the most successful bands made are of the larger

diameters, 10 in. and up, and that the percentage of rejected castings made by this process is small. (*The Iron Age*, vol. 107, no. 20, May 19, 1921, pp. 1289-1292, 4 figs. *d*)

TESTS OF CENTRIFUGALLY CAST STEEL

By Dr. Geo. K. Burgess

In an abstract on this subject printed on page 334 of Mechanical Engineering for May 1921, a statement was made that the distribution of carbon in the metal is not uniform, but the character of the lack of uniformity was not indicated.

In view of the importance of centrifugal casting as a recent development, Table 1, taken from the more complete publication

[1] Zones numbered from outside to inside of casting.

of the paper by Dr. Burgess, is of interest, as it shows that throughout the main part of the body of the centrifugally cast tube the distribution of carbon and other alloying elements is very uniform indeed, and it is only in the inner ring, which may be from 1/32 to 1/16 in. thick, that there is an increase of the lighter elements such as carbon or phosphorus, due evidently to the classification produced by centrifugal action. CENTRIFUGALLY CAST CAST-IRON PIPE

By Prof. Peter Gillespie

Description of the De Lavaud process of centrifugal casting of cast-iron pipe as carried on commercially in Canada.

The pipe is cast on the inside of a horizontal water-cooled rotating cylinder revolved on its axis by an impulse water wheel integral with itself and flared at one end to give the proper contour to the bell. The mold revolves in a cylindrical stationary casing and is supported at two points in its length by two pairs of friction rollers which are carried on the inside of this casing. In the manufacture of 6-in. water pipe the speed of revolution is about 550 r.p.m.

The molten metal is introduced into the mold by a cantilever spout which receives its supply from a tilting ladle operated by hydraulic pressure. The iron for the bell end is first supplied, immediately following which the casing and mold are moved backward by hydraulic means on horizontal ways away from the ladle and spout, thus enabling the latter to supply the metal continuously from the body of the pipe right out to the spigot end. The mold continues to rotate for perhaps 15 sec. after the last of the necessary iron has been supplied.

As it comes from the mold the iron is chilled and must be annealed. This annealing in a special furnace takes from six to seven minutes, after which the pipes are allowed to cool in still air.

Centrifugally cast pipes are lighter than sand mold pipes of similar bore, and, for example, in 4-in. size the standard C class weighs 23.3 lb. per ft. and the centrifugal pipe 15 lb.

The metal in centrifugally cast piping is of a dense, homogeneous character and the pipes are smooth inside and out. Tests were carried out by the writer at the University of Toronto on pipes and pipe material made by sand casting and spinning and it was found that roughly the tensile strength of the specimens from centrifugally cast pipe was 2.3 times as great as that for specimens cut from sand-mold pipes. In every other test the centrifugal modulus of elasticity was 2.3 times greater for machine-made pipe than for ordinary pipe, and a 6-in. pipe with walls 0.28 in. thick was found capable of sustaining an internal hydrostatic pressure of 1250 lb. per sq. in. without failure.

The pipe is manufactured in Canada by the National Iron Corporation, Ltd., Toronto. (*The Canadian Engineer*, vol. 40, no. 19, May 12, 1921, pp. 454–455, 4 figs., *d*)

STEEL-TUBE CASTING

Description of a process for the centrifugal casting of pipe in which the metal is melted electrically in the same mold in which it is subjected to the spinning process.

The process is carried on in four stages, the first consisting of casting the metal in bars of approximately the same weight and length as the final tube. These bars, together with such additional metal as is necessary, are placed into the mold which consists essentially of an outside steel shell, a refractory lining, and a graphite lining. The molds with the metal inside are closed airtight at both ends and placed in a rack where electric current is supplied to the terminals from a bus bar. They are left on the rack until the metal inside has thoroughly melted, and are then transferred to the spinning machine.

The spinning continues until the metal has solidified, the time varying with the kind of metal and to a certain extent with its external temperature. When the metal in the tube has set, it is allowed to cool until the contraction of the diameter of the tube is sufficient for it to be pulled out of the mold. It is then subjected to such heat treatment as may be necessary.

The advantages claimed for this process are its practically automatic character, permitting the use of unskilled labor; ability to control very strictly the temperature and composition of the metal, and the absence of gases in the mold. (*The Iron Age*, vol. 107, no. 20, May 19, 1921, p. 1300, 1 fig., *d*)

The Failure of Metals Under Internal and Prolonged Stress

At a joint meeting of the Faraday Society, the Institution of Mechanical Engineers, the Iron and Steel Institute, the Institue of Metals, the North-East Coast Institution of Engineers and Shipbuilders, the West of Scotland Iron and Steel Institute, and the Institution of Engineers and Shipbuilders in Scotland, held in London on April 6, the subject of failure of metals under internal and prolonged stress was discussed. Abstracts of several of the papers presented were printed in the June Survey Section. Excerpts from others follow.

The Prevention of Season Cracking in Brass by the Removal of Internal Stress, H. Moore and S. Beckinsale. In a previous paper before the Institute of Metals the writers showed that in 70:30 brass the internal stresses could be reduced sufficiently to prevent season cracking by annealing at low temperatures, and this without sensibly reducing the strength of the material or appreciably softening it. For the experiments whereby those results were obtained the writers used cups spun from fully annealed brass sheets and employed mercurous nitrate solution as the test

for the presence of injurious internal stress. The actual value of the stresses induced in the material by the spinning process could not be determined, and to that extent the experiments were incomplete. In the present paper the writers describe similar experiments conducted with specimens, the stresses in which, before and after annealing, could be calculated. Each specimen took the form of a strip of cold-rolled 70 : 30 brass, 6 in. long, 1 in. wide and either 0.02 in., 0.015 in., or 0.01 in. thick. Such a strip was clamped by its ends to a former block of 7 in. diameter. On the clamps being removed, the strip returned to the straight, showing that the elastic limit of the material had not been exceeded. The tension in the outer skin of the strip, when clamped, could therefore be calculated from the usual bending formula $p = Et/2r$. The strips, clamped to the former, were annealed at various temperatures for various lengths of time, and, on release, were found in all cases to assume a circularly bent form. If the radius assumed were r_1, then the stress in the material, after annealing and before release from the block, would be given by $p_1 = Et\ (r_1 - r)/2r_1r$. In this way the reduction of the initial stress effected by the annealing could be evaluated. Full data giving the results of the experiments are to be found in the original paper. In general the rate of reduction of the stress was found to increase as the annealing temperature rose, but in all cases it showed a marked slowing down after about one-half or two-thirds of the initial stress had been removed. For a brass of given hardness the higher the initial stress the higher was the stress remaining after a given heat treatment, while for a given initial stress and a given treatment the stress remaining after annealing decreased as the initial hardness of the material increased. The reduction in the internal stress is attributed to a slight plastic flow which occurs in the metal and which increases in amount with an increase of the annealing temperature, the duration of the annealing process and the magnitude of the initial stress. It is said that season cracking of brass can be eliminated in all cases by the application of a suitable low-temperature annealing to the manufactured article after the final cold-working operations. (*The Engineer*, vol. 131, no. 3408, Apr. 22, 1921, p. 427, *e*)

Intercrystalline Cracking of Mild Steel in Salt Solutions, A. J. Jones. Experimental study of the action of salt solutions on stressed mild steel. A number of riveted plates were prepared, the rivet holes in some cases being punched and in others drilled. The rivets were heated only to the minimum temperature necessary for the work, in order that comparatively high stresses might be induced. The plates were placed in a solution consisting of four parts of calcium nitrate to one part of water, at a temperature of about 145 deg. cent., and were examined at intervals. No corrosion or cracks could be detected on the outside surface of the plates after 23 days, but in 28 days two of the plates with punched rivet holes and one of the plates with drilled rivet holes showed a large number of distinct cracks. The other plates, including four with $^1/_2$-in. rivets, showed no cracks after 74 days; a number of these were then cut up, but no cracks were found on the inner surfaces. Plates produced in the same way, but normalized after riveting, showed no signs of cracks after 74 days in the calcium nitrate solution. The cracks produced as described above were examined and in every case were found to be intercrystalline. The microstructure of the plates was normal.

A second series of experiments was carried out on strips of mild steel $^1/_4$ in. thick, 1 in. wide and 4 in. long. Bolt holes were formed in pairs near the ends of the specimens, and the strips were tightened up and bent until their ends met. In calcium, sodium and ammonium nitrates and in potassium hydroxide the specimens developed intercrystalline cracks in from two and a half to five and a half days. No cracks were found after a number of days in specimens placed in sodium carbonate, ammonium sulphate, calcium chloride and a fused mixture of sodium and potassium nitrates. Specimens of bent plate identical with the above were annealed for one hour at 200, 300, 400, 600, and 900 deg. cent., respectively, after assembling and previous to placing in calcium nitrate and potassium hydroxide solutions. The plate annealed at 200 deg. cent. cracked in the calcium nitrate solution in 7 days. The specimen which had been immersed in the fused sodium and potassium nitrate mixture at 250 deg. cent. for 29 days cracked in the calcium nitrate solution in $8^1/_2$ days. The plate annealed at 300 deg. cent. cracked after 11 days in the calcium nitrate solution. None of the plates annealed at higher temperatures had cracked after 50 days. Two specimens similar to one another but bent through a smaller angle than the standard form cracked in 8 days and 6 days in calcium nitrate and potassium hydroxide solutions, respectively. (*Engineering*, vol. 111, no. 2885, Apr. 15, 1921, pp. 469–470, 7 figs., *e*)

Action of Internal Stress on Tool Steel, J. Neil Greenwood. Discussion on the failure of metals through the action of internal stresses, with special reference to tool steels. The opinion is advanced that internal stress falls into two main classes, namely, distortion of the equilibrium space lattice by cold-working, and suppression of an allotropic change as a result of rapid cooling. In the case of pure iron the change from the α form to the γ form is accompanied by a volume contraction of about 0.5 per cent. With the introduction of carbon another change takes place due to solution of iron carbide at and above 725 deg. cent., accompanied by transformation of the solvent iron to the γ state. This is associated with a volume change, which increases with the carbon content. The expansion due to solution of the carbide, however, does not equal the contraction due to the formation of γ iron even with 1.5 per cent carbon present. With 0.8 per cent carbon or more the contraction is approximately half of that due to the "α to γ" transformation in pure iron. The compressibility of steel is 0.62×10^{-6} per megabar, or 0.945×10^{-4} per ton per sq. in. In other words, a pressure of one ton per square inch causes a diminution in volume of 0.009 per cent; so that an external pressure of at least 50 to 60 tons per sq. in. would be required to cause a contraction equal to that resulting from the transformation from the α form to the γ form. A contraction of volume also occurs when α cementite is transformed into β cementite at about 200 deg. cent., but this contraction is very slight and only becomes appreciable in comparison with the other changes when there is about 2 per cent carbon present. In the process of hardening carbon steel internal stresses may be caused by the retention of iron in the γ form with a tendency to revert to the α form or by the suppression of the carbide phase change when this compression is accompanied with decrease in volume, or by the completion of the carbide phase change in the interior of the mass. (*Engineering*, vol. 111, no. 2887, Apr. 29, 1921, pp. 535–537, 1 fig., *g*)

Note on Phosphor-Bronze Bars, John Arnott. Examination of properties and behavior of phosphor-bronze hexagonal bars, presumably either cold-rolled or cold-drawn. Tensile tests on one bar gave: Yield point, 36 tons per sq. in.; tensile strength, 37 tons per sq. in.; elongation, 22 per cent on 2 in.; and reduction of area, 67.9 per cent. A similar bar was annealed at 600 deg. cent. for half an hour. Tensile tests on the annealed bar gave: Yield point, 7.2 tons per sq. in.; tensile strength, 21.12 tons per sq. in.; elongation, 81 per cent on 2 in.; and reduction of area, 80 per cent. It was evident that the very high yield point and tensile strength of the material could only have been obtained by excessive cold work. To prove this, pieces of the cars were immersed in mercurous nitrate solution. Cracks began to form in three minutes, and after an hour the bars showed both transverse and longitudinal cracks. The material, as received was apparently quite ductile. (*Engineering*, vol. 111, no. 2885, Apr. 15, 1921, p. 474, 2 figs., *e*)

The Spontaneous Cracking of the Necks of Small-Arm Cartridge Cases, W. C. Hothersall. Experimental study of the cause of cracking of the necks of small-arm cartridge cases during storage. Mercuric chloride and ammonia tests revealed the fact that the bulleting and necking operations, in which the mouth end of the case is swaged down to fit the bullet diameter, are most likely to originate the stresses causing the cracks. Of twenty cases placed in an acidified solution of mercuric chloride sixteen cracked immediately and all within forty-eight hours, while of a similar number suspended in ammonia gas all cracked in twenty-four hours. The cracks were similar to those which have been observed to form spontaneously, that is, mainly longitudinal, beginning at the mouth of the case and extending up the neck toward the shoulder. The presence of circumferential stress in the necks was confirmed by

withdrawing the bullets and measuring the diameter of the case close to the mouth. It was found that the necks were expanded by the withdrawal in some instances and were contracted in others. The former cases did not crack in mercuric chloride, while the latter did. Evidence was also found to the effect that the indenting process, under which the bullet is fixed in position by indenting the neck at three point to the circumferential groove in the bullet, can set up local stresses which will later cause the formation of cracks. The hardness of the neck of the case also influences the cracking, and it is possible that mercury derived from the fulminate of the cap composition acts as an accelerator. (*The Engineer*, vol. 131, no. 3408, Apr. 22, 1921, p. 427, *e*)

Experiences of Season Cracking During the Great War, Owen W. Ellis. Account of investigation undertaken during the war at the Metallurgical Laboratory of the Royal Laboratory Department of the Ordnance Factories, Woolwich, with a view to preventing season cracking of brass rods. After numerous experiments it was found that annealing for two hours at from 200 to 300 deg. cent. was quite sufficient to remove all internal stresses which would be likely to develop cracking. Since, however, the required mechanical properties of the material would not be affected by annealing at 400 deg. cent. and because annealing at 350 deg. cent. for about half an hour proved to result in the same beneficial effect as the annealing for a longer time at the lower temperature, this latter method of annealing was finally adopted as the standard workshop practice. (*Engineering*, vol. 111, no. 2885, Apr. 15, 1921, p. 474, *e*)

Short Abstracts of the Month

AERONAUTICS

Pulsating Wings for Aeroplanes, Harry Harper. An attempt to describe the theory and action of the wing said to have been invented by Prof. Raimund Nimfuhr of Vienna. It is stated that a full-sized load-carrying aeroplane is to be built and that the venture is to be financed by American capital.

In the Nimfuhr method an attempt is made to imitate the pulsating action of an insect's wing and it is stated that the Nimfuhr wing is hollow with air bags inside, the underneath section of the wing taking the form of a flexible membrane. This membrane can be set beating or pulsating by the action of pneumatic pumps which alternately fill or empty the air bags in the wing. These pulsations, extremely rapid, act powerfully on the cushion of compressed air which, in flight, is formed beneath the plane, and it is claimed that they will not only sustain but also propel a machine forward through the air, the air screw being eliminated entirely.

The Nimfuhr wing is also provided with flexible extremities at both ends, which, by pneumatic action, can be made to extend or contract in imitation of the "reefing" of a bird's wing. (*Motor Transport*, vol. 32, no. 843, Apr. 25, 1921, pp. 442–443, *d*)

[It may be mentioned in this connection that an unsuccessful attempt to build an aeroplane with pulsating wings was made in 1908 by a Russian engineer, Tatarinoff, working with the Russian War Dertm ent, in which the pulsations of the wing were to be produced by means of springs.]

AIR MACHINERY (See also Pumps)

Despatching Messages on Warships Pneumatically

Pneumatic Transmission of Messages on Warships. Description of pneumatic-despatch equipment extensively used on British warships.

Fig. 1 shows diagrammatically the layout of a ship installation. There are two electrically driven pumps situated respectively in the fan room and on the lower deck, and controlled from the main and auxiliary wireless-telegraph offices. Each valve has a reversing valve fitted above the silencers, by means of which the message pipes are put into connection either with the suction or pressure sides of the pipe, so that the message carriers may either be drawn from the far end of the tube or propelled in the opposite direction.

On the suction side there is an intake consisting of a simple bell-mouthed casting covered with wire gauze at the open end. The silencers are galvanized steel vessels with the internal baffle plates and are introduced to eliminate the pulsations of the air and deaden the sound of the exhaust.

The pumps in smaller installations have a vertical single-acting cylinder of 6 in. bore by 4 in. stroke running at 500 r.p.m. and driven by a $1^1/_4$-b.hp. motor. In larger installations horizontal pumps of a somewhat different type are used.

The brass tubes in which the condensers or carriers travel are of $1^1/_2$ in. internal diameter and are made in lengths of about 15 ft., the bands being of standard radius of 5 ft. with a minimum radius of $1^1/_2$ ft.

The type of carrier employed has an end pad of hard felt and a body of fiber. A light steel finger spring is fitted inside to prevent the papers being carried from falling out. The felt pad fits the tube and forms a piston against which the air pressure works.

The layout of Fig. 1 shows that a single transmission tube is carried from the installation in the main wireless-telegraphy room to the bridge, and that tubes are carried from the auxiliary wireless-telegraphy room to the main wireless-telegraphy room and

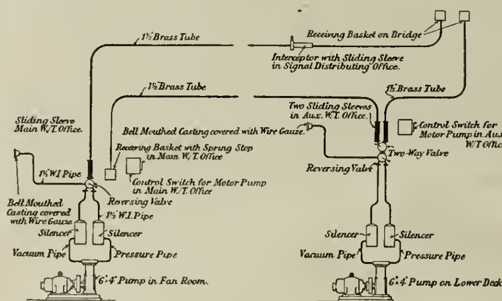

Fig. 1 Pneumatic Transmission of Messaoes on Warships (Diagrammatic Layout)

the bridge. On the tube leading to the bridge there is an interceptor in the signal-distributing office which consists of a sliding sleeve with a celluloid window and a valve or stop worked by a handle so that the carriers may either be stopped or allowed to pass through as desired.

The whole of this pneumatic-dispatch arrangement is simple and there is little or nothing to get out of order. It was very quick in operation and the time of transit on the longest tube on board ship is rarely more than 10 sec. (The speed at which the carriers travel in the tubes is approximately 30 m.p.h.). The original article describes also some of the secondary details of this apparatus. (*Engineering*, vol. 111, no. 2888, May 6, 1921, pp. 548–549, 10 figs., *dA*)

Pressure Losses in Compressed-Air Piping. Data of German experiences with various type of packing for compressed-air piping, taken from an investigation by a commission appointed by the German Board of Trade.

The test was made on a holiday. The piping of a large mine installation about 22 miles long with an average diameter of about 5 in. was kept under a uniform pressure of 6 atmos., all the underground workings being shut off. To maintain this pressure a compressor had to work continuously at 48 r.p.m., delivering roughly 3000 cu. ft. per min., which compensated for the leakage in the line.

As the consumption of the plant during the main shift amounts to 420,000 cu. ft. of free air, the loss due to leakage would be on an average of 30 per cent of the air delivered. A large part of this loss is attributed to the use of substitute packing instead of the standard rubber packing, as has been proved by additional tests. In these the air piping (60 ft. long, 3 in. in diameter, with 15 flange-packed joints) was put under the pressure of 6 atmos. The piping itself was absolutely tight and the pressure conditions in the line were recorded automatically. In these tests paper rings soaked in linseed oil and rubber rings were used for packing joints, with

the result that with an initial pressure in all cases of 6 atmos. the pressure with both plain paper rings and paper rings soaked in linseed oil at the end of 570 min. was 1 atmos., while with rubber rings the pressure from the same level only fell to 1.5 atmos. at the end of 1298 min., at which time the test was discontinued.

This would indicate that in the case of an installation of the size of the one tested the saving effected by using rubber packing rings is very material, indeed, and that the subject of packing rings is worthy of very serious attention. (Translated from the German engineer's report—source not specified. *The Compressed Air Magazine*, vol. 26, no. 5, May 1921, pp. 10092, *ep*)

FORGING

Friction Drop Stamp with Twin Brake Drums for Lifting and Holding Up

Twin-Drum Friction Lifter for Drop Stamps. With all its advantages the ordinary friction drop stamp has to overcome the handicap of considerable consumption of power together with heavy wear of brake linings. The new type built by a British concern is claimed to overcome some of these troubles through having two brake drums, one for lifting and one for holding up. As shown in Fig. 2, the flywheel is connected to the main shaft which runs at a speed from four to five times that of the ordinary lifter shaft. Connected to the same shaft is also a small central pinion of an epicyclic gear, the idlers of which mesh with an internal gear fixed to the rim

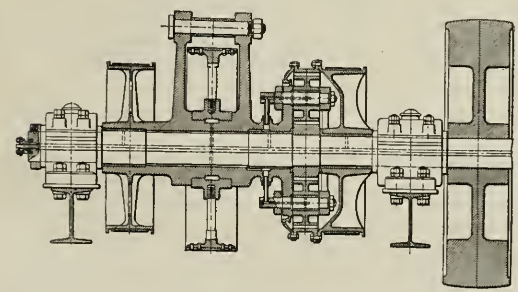

Fig. 2 Twin-Drum Friction Lifter for Drop Stamps

of a band-brake drum. The idlers themselves are mounted on a plate which is integral with the lifter, arms and pulley and also with the second band-brake drum seen on the left.

As regards the action, normally the central pinion revolves and the epicyclic gear causes the band-brake drum for the lifting movement to revolve also freely. If, however, this be arrested by the application of the right-hand brake, the idlers themselves revolve round the main shaft carrying the lifter, arms and pulley. The tup is held up by applying the band brake to the left-hand drum. The arrangement of the device is such that during holding up the only power used is that absorbed in gearing and the friction of the shaft and sleeve, whil no power is absorbed by slipping brake linings.

The design of the brake requires so little power to operate it that hand power can be employed without the introduction of any multiplying gear. The major portion of the braking load is taken on the brake drum attached to the lifting arms, so that the usual severe retarding loads on the gearing and motor are practically eliminated and the fluctuation of the load on the motor is greatly reduced. This is confirmed by data of tests given in the original article.

The brake linings used are pure asbestos and no water cooling is employed. (*Engineering*, vol. 111, no. 2889, May 13, 1921, pp. 584 and 588, 6 figs., *d*)

FUELS AND FIRING

Protection of Pulverized-Coal Plant from Dust Explosions and Fires, L. D. Tracey. Article based largely on data collected by the Bureau of Mines. Only the more important parts can be abstracted here.

The author, who is coal-mining engineer of the Pittsburgh Experiment Station of the U. S. Bureau of Mines, believes that it is practicable to install a vacuum-cleaner system in a coal-pulverizing plant, by means of which all parts of the building in which dust is liable to settle may be reached and cleaned. This has been done in some of the coal-crushing plants in France and Germany, and, in a few instances in our own country. Dust should never be brushed or swept up without first being thoroughly wetted down, and this applies not only to the pulverizing plant but also to the industrial portion of the operation.

The author strongly emphasizes the fact that accumulated dust and clouds of fine coal dust are highly dangerous when in close proximity to an open flame or mass of hot metal.

Excessively high drying temperature may result in explosion; moreover, as the author points out, coal dried at an abnormally high heat contains more moisture than when dried at a temperature of from 100 to 150 deg. fahr.

As regards some of the fires in the coal-conveyor lines between the bins and the furnace, the author believes that they oftentimes are due to spontaneous combustion in the storage bin. The coal in the bin becomes heated almost to the ignition point and the air current conveying it to the furnace supplies enough additional oxygen to bring it to incandescence. Because of this, whenever a plant has been shut down for a few days an examination should be made to ascertain the temperature of the coal in the bins before any pulverized coal is delivered to the transport lines.

Fine coal at a temperature of above 150 deg. fahr. should never be stored in a bin because of its liability to spontaneous combustion, and whenever a plant is to be shut down for a few days all storage bins should be emptied if possible. In the direct system of using pulverized coal the pressure of the distributing air should always be maintained well above that of the air supply for combustion purposes. Other recommendations of a practical nature are given in the original paper. (Paper read before the Engineers' Society of Western Pennsylvania, April 5, 1921, in Pittsburgh. Abstracted through *Coal Age*, vol. 19, no. 17, Apr. 28, 1921, pp. 746–749, *gp*)

INTERNAL-COMBUSTION ENGINEERING (See also Machine Parts)

Large British Gas-Driven Blowing Engine

1300-Hp. Gas-Driven Blowing Engine. Description of an engine to be operated on blast-furnace gas as built by a prominent British concern.

The power cylinders are 41.34 in. in diameter by 47.25 in. stroke and the bore of the air cylinder is 93.3 in., the engine being intended to deliver 30,000 cu. ft. of free air per minute. With the air compressed to 10 lb. per sq. in. normal blast pressure, the full load amounts to 1335 b.hp. The engine is chiefly interesting for the refinements of design which it embodies.

To eliminate casting and expansion stresses the power cylinders are cast in two halves and these are forced by hydraulic pressure over a cylinder liner of special cast iron and then bolted together. The water space is closed by a jacket casing of mild steel plate made in two halves, and a rubber joint between the jacket and the cylinder casting permits of relative motion caused by unequal expansion without stressing the cylinder castings.

The exhaust-valve box and valve seat (Fig. 3) consist of a separate outer casing and inner casing and valve seat, all of which are water cooled. The exhaust-valve seat is in the form of an inverted U-shaped ring of hard cast iron and easily renewable. The joint between the valve seat and the top of the inner casing is in the form of two concentric spigoted circular rings and is made tight by copper joint rings, the whole insuring efficient water cooling and ease of access for inspection.

The arrangement of the joint between the exhaust-valve box and the cylinder is such that any leak of gas at this joint or any leak of water at the joint of the valve seat becomes immediately visible, which is important as a leak in this joint may lead to cracking of a cylinder if allowed to continue.

The valve arrangement is somewhat different from usual, the inlet valve consisting of a main inlet valve and a gas valve flexibly attached to the spindle of the former; this permits both valves to close tightly, even if the seatings are worn unequally.

The pistons are water-cooled and have coned faces stiffened by pairs of internal diagonal ribs. Coned nuts are also provided at each side of the piston to permit of longitudinal adjustment so that the piston rings may work exactly edge and edge with the ends of the liner when running. Both pistons and piston rods are water-cooled, the cooling water being supplied at about 40 lb. pressure. The cooling water (Fig. 4) enters a bracket placed on the foundation below the middle distance piece. From this it passes by two short swiveling pipes into one of two pairs of long pipes, by which it is led up to the intermediate crosshead. Thence it passes by bent pipes, one portion flowing along the annular space between the piston rod and the internal pipe, through the piston and back by the internal pipe to the intermediate crosshead, from which it passes out into the swinging leg on the other side of the engine. The other portion of the water supply passes in a similar way through the second piston and rod.

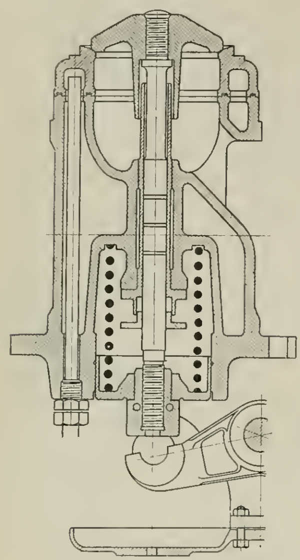

Fig. 3 Exhaust Valve of British 1300-Hp. Gas-Driven Blowing Engine

The cylinder barrels, covers, exhaust boxes and exhaust-valve seats are cooled by low-pressure water, while for the high-pressure piston water there are independent centrifugal pumps. The water from the pistons, cylinder jackets, covers, exhaust boxes and exhaust valve seats is discharged by separate pipes into open tun dishes mounted on the engine, so that the discharge from each part can be independently inspected, and the quantity and temperature individually controlled. (*The Engineer*, vol. 131, no. 3409, Apr. 29, 1921, pp. 451–454, 8 figs. and a 2-page supplement containing two more figures, *d*)

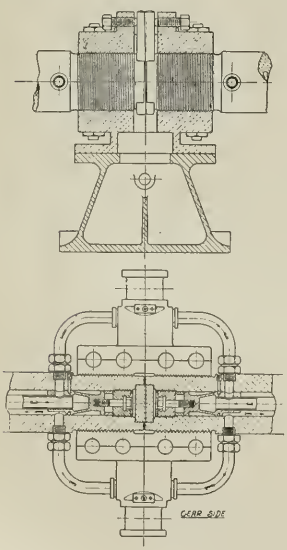

Fig. 4 Cooling-Water Arrangements for 1300-Hp. Gas-Driven Blowing Engine

A Unique Two-Stroke-Cycle Engine

"Silent Record" Internal-Combustion Engine. Description of an engine built by a British concern and working on somewhat unconventional lines. Essentially, the engine is a two-stroke cycle. Fig. 5 shows the arrangement of a two-crank engine. The cranks are at 180 deg. to each other and are connected to the charging-pistons C and D. These large pistons carry above them four working pistons A_1, A_2, B_1 and B_2. As the working pistons are about half the diameter of the charging pistons, the net area of the latter is about equal to that of the former. There is also a piston valve worked by the eccentric E. The action is as follows: On the down stroke the pistons C and D draw in explosive mixtures which are compressed on the up stroke and delivered to the inlet ports at the bottom of one of the working cylinders, the exhaust escaping through exhaust ports at the bottom of the other cylinder. The charging cylinders do not supply the working cylinders directly above them but those above the opposite crank, i.e., C supplies B_1, B_2 and D supplies A_1, A_2.

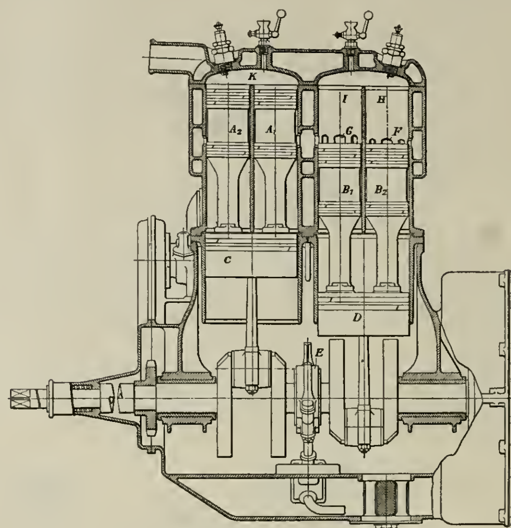

Fig. 5 "Silent Record" Two-Cycle Engine of Unconventional Design

Taking Fig. 5 in the position shown, the pistons A_1, A_2 have compressed the working charge into the combustion chamber K ready for firing. The charging piston C has also drawn in a charge and slightly compressed it in the space between the pistons. The pistons B_1, B_2 have finished their working stroke, and B_1 has fully uncovered the exhaust port G while B_2 slightly later uncovered the inlet port F. The piston valve now allows the charge compressed by the charging piston C to flow through the inlet port F into the cylinder H, from which it flows across the combustion chamber and down the cylinder I, pushing the exhaust out of the port G in front of it.

The charge in the combustion chamber K is now fired, and the pistons A_1, A_2, descend. As they do so the piston valve puts the space above C into communication with the carburetor and allows new mixture to be drawn in, while it puts the space above D into communication with the inlet port uncovered by the piston A_2. The charge in H and I is compressed and fired at the top of the stroke, while the pistons A_1, A_2, uncover exhaust and inlet ports corresponding to F and G, and the cycle recommences.

As compared with the ordinary two-stroke-cycle engine, the advantage of the design described above lies in the fact that crankcase compression is not used and also that positive distribution of the mixture to the charging cylinders is secured. It is also claimed that a more complete stratification is obtained.

The engine shown has four working cylinders equivalent to two cylinders 3 in. by $3^1/_2$ in., and develops 10 b.hp. at 1600 r.p.m. (*Engineering*, vol. 111, no. 2888, May 6, 1921, p. 565, 2 figs., *d*)

MACHINE PARTS

Aluminum Pistons. Frank Jardine and Ferdinand Jehle, Mem. Am.Soc.M.E. Discussion of performance and design of aluminum pistons.

According to the authors the most important function which the piston performs is that of converting heat into mechanical energy. Providing a path for some of the waste heat is a secondary duty, and it is of the utmost importance that the performance of this secondary duty interferes little or none with the performance of the first. Unfortunately, up to the present time there has been interference. The heat passing through the piston causes such undesirable effects as self-ignition of the charge and excessive expansion of the skirt which necessitates a large clearance when the piston is cold. The clearance trouble is aggravated when aluminum is substituted for cast iron, because of the greater expansion of the former.

As regards the design of aluminum pistons, the authors point out that it was Col. E. J. Hall who arranged the piston so as to provide a good path for the flow of heat from the head of the piston to the water jacket, but his design, while successful in aviation motors, did not prove adaptable to automobile engines.

The authors give their own formula for the head thickness of aluminum pistons.

The most interesting part of the paper, which, unfortunately cannot be abstracted owing to lack of space, reports tests in which the actual temperatures in pistons in operation in an engine have been measured at various speeds and horse-power outputs.

From these tests it was found that piston temperatures, especially those of the head, were very susceptible to changes in fuel consumption. Also, it was discovered that changes in cooling-water temperatures brought about a marked difference in the piston temperatures. Much of the heat was found to leave through the rings and the temperature immediately below the rings was found to be several hundred degrees lower than the head temperature. This brings up an interesting discussion of the influence of the temperature of the piston head on the expansion of the skirt, in addition to the thermal expansion due to individual temperature of the skirt. In fact, the authors come to the conclusion that separating the head from the skirt, in so far as this can be done mechanically, would relieve the skirt of mechanical expansion in certain directions and permit using a smaller clearance than would otherwise have been necessary. (*Journal of the Society of Automotive Engineers*, vol. 8, no. 5, May 1921, pp. 397–403, 9 figs., *ge*)

MACHINE TOOLS

Machine for Cutting Double-Helical Gears

Sykes Double-Helical-Gear Generator. Description of a gear generator based on the principle that the cutters take the form of pinions in gearing contact with the wheel being cut, and, with the latter, are rotated during the process of generation. The reciprocating motion given to the cutter is combined with the helical movement in order to secure teeth set at the required angle, in this instance the standard angle of 30 deg.

The reciprocating motion of the cutters across the face of the work is combined with two other movements. The first of these is an oscillating helical movement to make the cutters follow the lead of the gears to be cut, while the second is a continuous revolution to keep the cutters in unison with the revolution of the work blank. In modern types of Sykes generators the first movement is obtained with the bars and guides all to one side, one set having a hollow spindle through which the other is passed so that the guides can be placed close together on the left side of the machine.

The large guides and cast-iron housings with their two guiding faces are shown in Fig. 6. The fixed member is held in each case in a revolving housing and the reciprcoating members work to and fro in the same elements. This design permits of both members being machined in exactly the same way. The fixed part is in two sections, the joint between the two being straight and in line with the axis. This enables wear to be taken up, one section being fixed and the other capable of adjustment longitudinally.

The continuous revolution of the cutter is obtained by large indexing worm wheels driven by worms on vertical spindles. In order to obtain the greatest accuracy of pitch the two indexing worm wheels are made as large as possible.

The cutters have to register correctly together, which is insured by means of two toothed clutches. The work is set up to the cutters until they just mark it and then they are adjusted by the vertical worms, the clutches being afterward secured down so that the driving gears are engaged again.

The following is said to be a typical example of marine turbine gears cut on this machine: Transmitting 2500 hp. with the primary pinion running at 4800 r.p.m., the smallest pinion of the set was of 5 in. diameter, 14 in. face and 5 diametral pitch, while the largest was 50 in. in diameter, 18 in. face and 3 diametral pitch. A 0.5 per cent carbon steel pinion of 14 teeth 5 diametral pitch and 8 in. wide can be cut in 60 min. Wheels of cast iron of 5 diametral pitch, 6 in. wide and 45 in. in diameter, take 7 hr. Cast-steel wheels 50

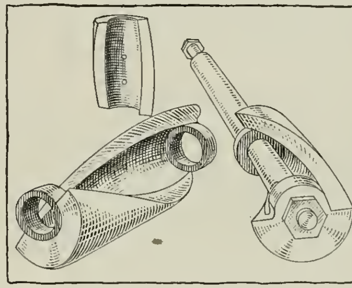

Fig. 6 Helical Guides for Cutter Spindles in the Sykes Double Helical-Gear Generator

in. in diameter, and of 16 in. face and 3 diametral pitch are cut in 14 hr. Rolling-mill pinions integral with 9-in. shaft, of 0.7 Mn and 0.5 per cent carbon steel, 25 teeth of $1^3/_4$ in. pitch, take about 9 hr. each; 48-in. turbine reduction gears with 18 in. face, of a maximum degree of accuracy, take about 24 hr. each. (*Engineering*, vol. 111, no. 2887, Apr. 29, 1921, pp. 520–522, 7 figs., *d*)

PRODUCER GAS

Water-Gas Apparatus and the Use of Central District Coal as Generator Fuel, Wm. W. Odell. Many gas companies are facing considerable financial difficulties as a result of the greatly increased cost of gas oil used to enrich water gas. Reconstruction of plants to manufacture coal gas instead of water gas is difficult, if not economically impossible, under present conditions. One of the economies by which an attempt is being made to meet the situation is the use of cheaper grades of coal to replace anthracite or coke, and the present paper presents certain preliminary studies bearing on the possibility of substituting Indiana and Illinois coal for coke in water-gas generator sets.

Prof. T. S. C. Lowe, of Norristown, Pa., appears to have established the basic principle of water-gas generation some 45 years ago.

Many attempts have been made to use bituminous coal as generator fuel with varying success, and the paper mentions eleven objections which have so far prevented the general use of coal in place of coke fuel. Several designs made to meet these objections are discussed, such as the Loomis, the Fahnehjelm, Rew, K & A, and Smith.

The distribution of heat in a water-gas set is discussed in detail and various heat balances presented. An interesting part of the paper is a list of the main requisites for the efficient production of good water gas in quantities from coke fuel and a discussion of coke and coal as generator fuel. From this latter it appears that successful utilization of central-district coal as a generator fuel seems to require the maintenance of the following conditions:

1 Higher temperatures in the fuel bed
2 Larger body of completely heated fuel
3 Increased production of blue gas per given amount of blast or an increased amount of blast with an auxiliary utilization of the excess combustible blast gas
4 A means of carbonizing the coal in the generator without the

formation of a mat or cake in the upper part of the fuel bed

5 The utilization of an increased air-blast pressure to offset the increased resistance of the coking fuel to the passage of air, or the equivalent by a change in design of the set
6 A means of control of clinker, particularly edgings
7 A means of properly distributing the fuel in the generator.
8 A means of thoroughly atomizing the oil
9 A generator so proportioned that the steam used during the run has ample time of contact with the incandescent fuel for the completion of the blue-gas reaction.

The principles of design of a generator set suited for central-district coal is discussed. It is stated, however, that although clinker difficulties may be partly eliminated by the method suggested, it is doubtful if they can be entirely eliminated in that manner. (Paper prepared under a coöperative agreement with the Illinois State Geological Survey and the Engineering Experiment Station of the University of Illinois through its Department of Mining Engineering, published as *Technical Paper No. 246, U. S. Bureau of Mines*, Washington, D. C., 1921, *gp*)

PUMPS

Air-Lift Pumping Plant with Remote Control

A Modern Air-Lift Pumping Plant, John Oliphant. Description of an air-lift pumping plant installed by the Philadelphia & Reading Co. at Telford, Pa. In this case the problem was to deliver the water from an artesian well into an elevated tank located at a distance from the well and to control the operation as to starting and stopping from another distant point, and at the same time to control the cooling water supplied to the water-jacketed air cylinder of the compressor, the pumping being at the rate of approximately 100 gal. per min.

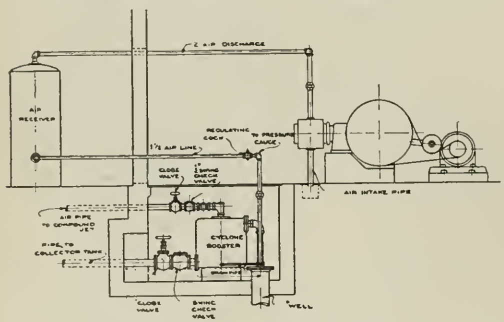

Fig. 7 The Compressor, Air Receiver and Well in the Air-Lift Pumping Plant of the Philadelphia & Reading Co., at Telford, Pa.

The well was equipped with a 3 in. air-lift footpiece having outside air connections and a multiple-orifice mixing tube located centrally in the mixing chamber and discharging the air through a number of small openings into a relatively thin sheet of ascending water. It is claimed that this design secures a complete emulsion of air and water in the footpiece.

In the pit around the well head and connected to the reduction pipe was located a Sullivan cyclone booster 30 in. in diameter by 30 in. high. The combined air and water was discharged into this booster and separator near the top and at one side at a tangent to the periphery under high velocity from the well, causing it to swirl and thus effect a perfect separation of the air and water. The water leaves the separator at the bottom, also at a tangent to the periphery, and the air passes off at the top. The air pressure in the booster is controlled by a valve set to maintain the pressure required by the head against which the booster is discharging, this head being caused by friction in the pipe (536 ft. of horizontal run, a rise of 14 ft. from the booster to the base of the elevated tank, and the elevation of 66 ft.). The arrangement of the compressor, air receiver and well is shown in Fig. 7. In addition to this the original article contains an interesting drawing showing the pipe layout for the air lift.

The regulation as installed is of considerable interest. As it was required to control the plant from a distant point, it became necessary to unload the compressor when it stopped, and in starting to permit the compressor to get up to speed before the load was thrown on. This was accomplished by means of a flyball governor on the compressor that acted as an unloader when it was at rest, and did not admit air to the compressor until the speed had elevated or extended the controlling balls. It was also necessary to shut off the cooling water to the air cylinder when the compressor was stopped, and turn it on again when started. This was accomplished by placing a balanced solenoid valve of the normally closed type in the cooling-water line controlled from the starting control at the switchboard.

A push button, together with a relay, were located at the pumping station. In the railway station, 3600 ft. from the plant, another push button was installed and an electric-connected pressure gage at the base of the elevated tank was connected to a bell at this latter point to give the alarm when the tank was full of water. Provision was then made for starting and stopping the plant either at the pumping station or at the station 3600 ft. away. As the compressor is of the enclosed, splash-lubrication type, and is equipped with a McCord force-feed lubricator, it is safely manipulated from the station, where a push of the button by the station agent starts the pumping and when notified by the ringing of the bell that the tank is full, another push stops it. The air and water lines were laid so as to drain back into the booster, and a small connection with a partly opened valve was made from the bottom of the booster back into the well, so that all connections drain to obviate freezing in cold weather during idle periods.

A record is given of a test run, from which it would appear that with a total head of 149 ft. the theoretical horsepower required was 3.55 hp. while the actual electrical input was 12.5 hp., which would indicate an overall efficiency (wire to water) of 28.5 per cent. (*Railway Maintenance Engineer*, vol. 17, no. 5, May 1921, pp. 172–174, 3 figs., *d*)

Rotary Pump of Novel Design

Exeter Rotary Pump. The Exeter rotary pump built under the Feuerheerd patents is an application to pumps of the principle of the square-hole drilling device, in which a triangular bit functions inside a restraining square former of equal size. The irregular spaces increasing and diminishing in volume as the two rotate together are utilized to admit and eject the fluid.

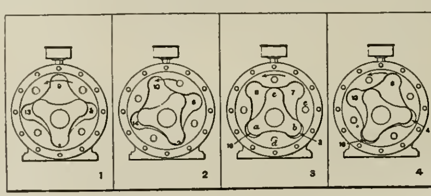

Fig. 8 Cycle of Movement of the Rotors of the Exeter Pump

Fig. 8 shows the cycle of movement of the rotors of the Exeter pump. One of the interesting features is that the pump is self-priming. It has, of course, no valves. As there are no surfaces rubbing against each other, this pump may be used to handle dirty and gritty water. The capacity of the pump per revolution is equal to three times the volume of space 9 in volume 1 of the illustration. (*The Nautical Gazette*, vol. 101, no. 19, May 7, 1921, pp. 597 and 609, 1 fig., *d*)

ENGINEERING RESEARCH

A Department Conducted by the Research Committee of the A.S.M.E.

Strains in Crankshafts Due to Vibration

The Special Committee of the Research Committee on the Strains in Crankshafts due to Vibration is about to begin its actual work. The tentative plan of investigation is given below. The membership of the Special Committee is as follows:

N. W. Akimoff, *Chairman*	Comdr. Wm. McIntee
B. A. Behrend	F. Hymans
Prof. A. H. Beyer	Lt-Comdr. M. W. Torbet
John E. Burkhardt	C. P. Wetherbee
H. C. Dickinson	Dr. E. C. Newcomb
Comdr. F. C. Cleary	Prof. Wm. H. Kavanaugh

General Object and Scope of Work

I Descriptive Part:
Shaft failures:—Description of circumstances and conditions
Vibrations:—Description of circumstances and conditions

II Design:
Usual principles of, in marine, land and automobile practice
Illustrations
Counterweights
General remarks on lubricating systems

III Elements of theory of elasticity required for this investigation

IV Dynamics of the reciprocating mechanism in its relation to subject at hand

V Elements of the theory of vibrations with special reference to torsional vibrations

VI Theory of damping devices

VII Methods of measuring amplitudes of vibrations and strains in crankshafts

VIII Outline of an analytical method of finding torsional "periods"

IX Synopsis of conclusions.

Research Resume of the Month

A—Research Results

The purpose of this section of Engineering Research is to give the origin of research information which has been completed, to give a résumé of research results with formulas or curves where such may be readily given, and to report results of non-extensive researches, which in the opinion of the investigators do not warrant a paper.

Automotive Vehicles and Equipment A6-21. Steering Knuckles. Report No. 265 of the Experimental Department of the Packard Motor Car Company gives a formula for the design of a steering spindle and steering arm for racing cars. The spindle is designed by the formula

$$D = \sqrt[3]{w\,d/12{,}150}$$

in which D = diameter of spindle at big end in inches, w = total weight on front wheels in pounds, and d = diameter of front tire in inches.

The material shall conform to specifications 6135 or 3435 of the S.A.E. and shall be heat-treated to give the following:

Elastic limit	110,000 lb. per sq. in.
Tensile strength	125,000 lb. per sq. in.
Elongation in 2 in.	17 per cent
Reduction in area	55 per cent
Brinell hardness	255–386

A steering arm shall be designed by the following formulas:

$$Z_b = \frac{w\ a}{18{,}000\ b}$$

$$D_b = \sqrt[3]{\frac{w\ a}{1765\ b}}$$

$$u = \sqrt[3]{\frac{w\ a}{3000\ b\ k^2}}$$

in which Z_b = minimum section modulus at point of lever arm a
w = total weight on front wheel in pounds
a = distance from center plane of wheel to spindle pin axis in inches
d = distance from spindle-pin axis from center of gravity to steering arm section in inches
D_b = diameter at section of arm
u = width of rectangular section with thickness v in which $k = u/v$

The width u shall be the dimension measured in the horizontal plane. The maximum value of k shall not exceed 2. Material used for the steering arm is the same of that of the steering spindle, but the heat treatment gives elastic limit at 100,000 lb. per sq. in., tensile strength 120,000, elongation in 2 in. 18 per cent, reduction of area 55 per cent and Brinell hardness 228 to 269. Packard Motor Car Company, Detroit, Mich. Address L. M. Woolson, Experimental Engineer.

Chemistry A1-21. Soda Glass. A soda glass of 30 per cent sodium oxide is produced as a by-product of one of the processes of refining nickel. This may be used as a black glass suitable for counters or table glass, and by leaching this glass a soluble alkali can be recovered with a residue which has the same properties as the water softener permutit Address John F. Thompson, Manager Technical Department, International Nickel Company, 43 Exchange Place, New York.

Hydraulics A1-21. Centrifugal Pumps. The measurement of hydraulic losses due to centrifugal pumps has been studied at the University of Michigan. Six propellers have been used and the effects of various dimensions have been carefully studied. The effect of air leakage in the suction line has been studied as well as the effect of this on capacity. Address Prof. J. E. Emswiler, University of Michigan, Ann Arbor, Mich.

Hydraulics A2-21. Reservoir Pipe Connection. An investigation has shown that the velocity head in the pipe line at the entrance to a reservoir is not entirely lost. Address Prof. J. E. Emswiler, University of Michigan, Ann Arbor, Mich.

Internal-Combustion Engines A2-21. Flame Propagation in Automobile Engines. For a graduating thesis at Rose Polytechnic Institute, R. J. Owen and M. G. Flesher determined the rate of flame propagation in an automobile engine in the following manner: One spark plug was removed and a special casting made which permitted the attachment of an ordinary indicator suited for gas-engine testing, together with a spark plug having extended plug removed. An electric motor through suitable reduction gearing drove at constant speed a drum which communicated motion to a continuously moving strip of paper. The strip of paper was carried across the drum of the indicator so that a continuous card was traced. At the same time a standard tuning fork of 250 vibrations per second traced a sinuous line which formed the measure of time intervals. The experiments were made on an Atlas-Knight engine fitted with a Stromberg carburetor. The auxiliary air was closed off and a pipe extension fitted to the main air intake. A pitot tube in this pipe extension served to measure the air used. The gasoline used in a definite time was also determined, so that from a combination of the two readings the ratio of air to gasoline could be found. Tests were made with different makes of gasoline and different proportions of air to gasoline. As was anticipated, the rate of flame propagation is much more rapid for these mixtures than for mixtures of gas and air as determined by previous experimenters. The time interval between ignition and the attainment of maximum pressure varied from 0.004 sec. to 0.014 sec. Each grade of gasoline showed a maximum rate of combustion for a definite ratio of air to gasoline, either side of which ratio the combustion was slower. Various trade gasolines gave the most rapid combustion at ratios of 12 to 1 or 13 to 1. A mixture of gasoline and benzol containing about 40 per cent of benzol showed most rapid combustion with a mixture of 16 to 1. Address Prof. F. C. Wagner, Rose Polytechnic Institute, Terre Haute, Ind.

Metallurgy and Metallography A10-21. Losses in Aluminum and Aluminum Alloy Melting. Report No. 2239 of the Bureau of Mines by Robert J. Anderson discusses the losses in melting non-ferrous metals. The factors to be considered are:

1. The type of furnace
2. The melting temperature
3. The length of time for melting and superheating to pouring temperature
4. The length of time during which metal remains in the furnace at pouring temperature
5. The constitution of furnace atmosphere in contact with the metal
6. The volume of air and products of combustion passing over the metal per unit of time.

The fuel consumption depends on furnace design, air supply fuel used relation of fuel to air, design of burner, and method of removnig waste gases. The domestic output of aluminum was 225,000,000 lb. per year for the year 1918 as primary metal. The amount of aluminum produced in the form of alloy amounts to 30,000,000 lb. The average recovery from remelting borings and scrap amounts to 65 or 70 per cent and the borings amount to 15 per cent of the casting. The average recovery from furnace dross containing 30 to 60 per cent metallics is not over 80 per cent. All aluminum is melted at least twice and much of it at least several times. The principal loss is due to oxidization, the average loss being about 2 per cent. The great fuel loss in melting aluminum is due to the fact that the furnaces used for this purpose utilize probably from two to eight per cent of the heat of the fuel. The probable loss in melting aluminum amounts to about $3,000,000 per year. Address Director, Bureau of Mines, Washington, D. C.

Metallurgy and Metallography A11-21. Volatilization Process. The Research Department of the School of Mines and Engineering of the University of Utah is publishing in connection with the U. S. Bureau of Mines a bulletin on the volatilization process of abstracting metals from their ores. Patents have been issued as a result of this research which have been assigned to the University for the use of the public. The Bulletin will appear in about six months. School of Mines and Engineering, University of Utah, Salt Lake City, Utah.

Properties of Engineering Materials A4-21. Mill Scale in Pipes. The National Tube Company has found that mill scale on the inside of pipes accelerates pitting and they have devised a mechanical means for its removal. This is an improvement in one of the operations of galvanizing and gives a better appearance to the pipe. Address F. N. Speller, Metallurgical Engineer, National Tube Company, Pittsburgh, Pa.

Pumps A1-21. Centrifugal Pumps. An improved form of centrifugal pump which gives equal efficiencies at varying heads. Address Prof. J. E. Emswiler, University of Michigan, Ann Arbor, Mich.

Welding A2-21. Oxy-Acetylene Welding and Cutting Blowpipes. R. S. Johnston of the Bureau of Standards has recently made a report which is printed in Mechanical Engineering for May 1921. The results of the investigation show that blowpipes in which oxygen is delivered at pressure in excess of the acetylene are subject to flashbacks. All blowpipes are subject to flashback phenomena on account of inherent defects in design. Conditions producing flashback are those existing within the blowpipe tip and head which choke off the flow of one of the gases. This back pressure is due to the confining or restricting the volume flow at the tip end. A blowpipe that cannot maintain under all operating conditions a neutral flame cannot be expected to produce sound welds. All blowpipes tested were incapable of maintaining a neutral flame under all conditions. The average operator checks the acetylene gas flow too much and actually develops an oxidizing rather than a neutral flame. A more satisfactory instrument than the blowpipes investigated will be necessary before the possible limiting strength, ductility or efficiency of welds may be determined. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

B—Research in Progress

The purpose of this section of Engineering Research is to bring together those who are working on the same problem for coöperation or conference, to prevent unnecessary duplication of work and to inform the profession of the investigators who are engaged upon research problems. The addresses of these investigators are given for the purpose of correspondence.

Air B4-21. Air Through Orifices. Experiments to show the coefficients used in determining the flow of air through orifices. Mason Laboratory, Sheffield Scientific School, Yale University, New Haven, Conn. Address Prof. E. H. Lockwood.

Aircraft B1-21. Air Propellers. Prof. W. F. Durand and E. P. Lesley are making a general survey of the tests made on 86 model air propellers tested during the past three years and reported on in progressive parts. The present investigation has for its purpose the general comparison and analysis of all results, reduction to non-dimensional coefficients and representation in tabular and graphical form with nomographic charts for purposes of design. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Apparatus and Instruments B5-21. Observation of Explosion within Gas-Engine Cylinder. See *Internal-Combustion Engines B5-21.*

Automotive Vehicles and Equipment B2-21. Tire Friction. Rolling friction of automobile tires. Mason Laboratory, Sheffield Scientific School, Yale University, New Haven, Conn. Address Prof. E. H. Lockwood.

Automotive Vehicles and Equipment B3-21. Dynamometer Tests. Dynamometer tests of automobile power plants. Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Automotive Vehicles and Equipment B4-21. Radiators. Tests of automobile radiators, including description of types with their construction and the heat transmission. Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Automotive Vehicles and Equipment B5-21. Farm Tractors. A bulletin is being prepared by the Engineering Experiment Station of Purdue University on the tests of six farm tractors and one army caterpillar. These tests are made independently of soil conditions. Address Dean A. A. Potter, Purdue University, Lafayette, Ind.

Chemistry B1-21. Nickel Compounds. An investigation of the properties of nickel compounds for commercial uses such as for paint and printing pigments, body colors for ceramic wear and soluble nickel compounds for fungacides. The study so far made indicates that black nickel sulphide, black nickel hydrate, and black nickel chromate would be valuable as pigments for paint and printing, while nickel oxide with zinc oxide seems to offer promise in the production of body colors in ceramic ware. Address John F. Thompson, Manager, Technical Dept., International Nickel Co , 43 Exchange Place, New York.

Fire Prevention B1-21. Fire Possibility of Locomotive Cinders. An investigation covering three years of work to determine actual fire hazard of locomotive cinders. Cinders of different sizes heated to known temperatures of 2000 deg. fahr. were dropped on various kinds of roofing with artificial wind velocities varying from 5 to 30 miles per hour. Cinders used so far have come from anthracite and bituminous coals. North Dakota lignites are now being examined. Address Prof. G. A. Young, Purdue University, Lafayette, Ind.

Fuel Utilization B1-21. Oil Torches and Furnaces. The design and performance of oil torches and oil heating furnaces operated on a vacuum system in place of the ordinary pressure system. University of Minnesota, Minneapolis, Minn. Address Prof. J. J. Flather.

Heat B15-21. Heating Boilers. Tests on two low-pressure heating boilers with various kinds of fuel have recently been made at the Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Heat B16-21. Steam Radiators. A study of heat transfer through radiators. University of Minnesota, Minneapolis, Minn. Address Prof. J. J. Flather.

Heat B17-21. Heat Transmission. A study of the physical properties of hydrocarbons which bear upon the problem of heat transmission is being made by W. R. Eckart. The study will include a review of all published data available. An attempt will be made to make this of practical use. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Heat B18-21. Heat Transmission. An experimental investigation of heat-exchange apparatus with fluids of different physical properties and under varying rates of flow is being continued by W. R. Eckart. Experimental work previously reported has been continued and in addition an extended series of tests with varying mixtures of steam and gasoline vapor on one side and water and oil on the other side are being made. The pressure and rates of flow are varied. Address Prof. W. F. Durand, Leland Stanford Junior University, Stanford University, Cal.

Internal-Combustion Engines B3-21. Hot Spot. An investigation by Prof. O. C. Berry and C. S. Kegerreis to determine the rate of vaporization of various fuels including kerosene at various temperatures and atmospheric pressure. Address Dean A. A. Potter, Purdue University, Lafayette, Ind.

Internal-Combustion Engines B4-21. Factors Affecting Exhaust Temperatures. In order to properly utilize the hot spot it is necessary to know limits of temperature range in the exhaust gases from internal-combustion engines. Prof. O. C. Berry and C. S. Kegerreis have investigated this problem in connection with the effect of cooling-water temperature, inlet air, ignition timing, gasoline-air ratio, speed and load. A bulletin is being prepared on this matter. Address Dean A. A. Potter, Purdue University, Lafayette, Ind.

Internal-Combustion Engines B5-21. Observation of Explosion within Gas-Engine Cylinder. The Bureau of Standards has developed a glass window attached to the spark plug and observed by means of a stroboscopic disk so as to observe the ignition flame during different times of the stroke. The device will probably be of value in permitting observations on the duration of luminous flame during the power stroke. The characteristic differences of color and brightness at different phases of combustion and their averages with changes in ignition timing, mixture ratio, compression pressure and other quantities. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Lubricants B2-21. Lubricating Oils. A set of tests on various lubricating oils in connection with gasoline motors to determine the best oil under operating conditions. These oils are also being examined for their physical and chemical characteristics. New tests are being devised to determine the value of an oil without making a breakdown test on an engine. University of Minnesota, Minneapolis, Minn. Address Prof. J. J. Flather.

Lubricants B3-21. A conference was held in Philadelphia at the Philadelphia Electric Company and attended by a large number of representatives from various industrial concerns and the Bureau of Standards to discuss the possibility of preparing uniform specimens for steam-turbine oils. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Machine Design B2-21. Friction in Ball Bearings. Tests on the friction in ball bearings are contemplated at the Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Machine Design B3-21. Fatigue and Machinability of Metals. A research on the fatigue and machinability of metals is being planned at the Mason Laboratory, Sheffield Scientific School, Yale University. Address Prof. E. H. Lockwood.

Metallurgy and Metallography B8-21. Mechanical Treatment of Steel. Elaborate study of the effects of the mechanical treatment on the properties of steel through rolling is being made at the Bureau of Standards. After rolling the steel the specimens are prepared for various mechanical tests including metallographic examination. An endeavor will be made to measure the effects of the various factors which enter into the mechanical treatment of metals. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Petroleum Asphalt and Wood Products B1-21. Prevention of Evaporation Losses in Lease Tanks. Report No. 2236 of the Bureau of Mines by J. H. Wiggins gives the results of tests performed in Oklahoma. The tests showed that by making the tanks gastight losses can be prevented which will soon pay for the cost of capping the tanks. The present method of handling oil shows that about $3^1/_2$ per cent of production is lost on the lease, of which a larger part could be saved by gastight tanks. Bureau of Mines, Washington, D. C. Address Director.

Properties of Engineering Materials B1-21. Monel Metal. An investigation on the mechanical properties of monel metal, dealing especially

with repeated stresses, alternating stresses, torsional stresses, and impact. Recent tests with the Izod machine indicate that monoi metal has a higher degree of toughness than any known metal or alloy. Address John F. Thompson, Manager, Technical Dept., International Nickel Company, 43 Exchange Place, New York.

Refrigeration B1-21. Refrigerating Constants. The Bureau of Standards is continuing its program of determining the constants used in refrigeration. So far the Bureau has determined the specific heat of brine, the specific heat and latent heat of ice, the properties of saturated ammonia, and heat transmission through certain insulating materials. Work is now being done on the properties of superheated ammonia and after this the properties of other refrigerants will be undertaken. These will include carbon dioxide, ethyl and methyl chlorides, and possibly sulphur dioxide. Bureau of Standards, Washington, D. C. Address S. W. Stratton, Director.

Road Material and Equipment B1-21. Bituminous Pavements. A bulletin is being prepared for the Engineering Experiment Station of the A. and M. College of Texas by Prof. Roy M. Green on the bituminous pavements in Texas, with exception of the bithulithic. Professor Green is now connected with the Western Laboratories at Lincoln, Neb.

C—Research Problems

The purpose of this section of Engineering Research is to bring together persons who desire coöperation in research work or to bring together those who have problems and no equipment with those who are equipped to carry on research. It is hoped that those desiring coöperation or aid will state problems for publication in this section.

D—Research Equipment

The purpose of this section of Engineering Research is to give in concise form notes regarding the equipment of laboratories for mutual information and for the purpose of informing the profession of the equipment in various laboratories so that persons desiring special investigations may know where such work may be done.

Julian Simsohn and Associates D1-21. The laboratory of Julian S. Simsohn, Chemical Engineers, of Philadelphia, Pa. is equipped for research in water purification, fuels, and combustion in connection with power-plant operation. The work of this corporation is covered by yearly contracts with weekly inspection and tests of plant operation. The service was established in 1912. Address Julian S. Simsohn, Chemical Engineers, Philadelphia, Pa.

E—Research Personnel

The purpose of this section of Engineering Research is to give notes of a personal nature regarding the personnel of various laboratories, methods of procedure for commercial work or notes regarding the conduct of various laboratories.

Cornell University E1-21. Research Activities. The Department of Experimental Engineering of Sibley College, Cornell University, has been active during the past year along several lines. Investigations made are not reported by printed bulletins and therefore printed matter is not available. The work completed includes the following:

1 Investigation of various makes of hand tire pumps for efficiency and capacity

2 Tests on a new vertical Una-Flow engine

3 Study of the effect of oversize tapping of nuts on the strength and character of the failure of bolts

4 Effect upon the strength of railroad rails of various ways of anchoring

5 Comparative tests of cast iron and of steel radiators

6 Investigation on the mechanical efficiency of a Ford engine

7 Investigation of the forces required to drive staples through paper

8 Study of the proper heat treatment for cotton bailing wire and clips.

The Leather Belting Exchange has moved its belt-testing laboratory from Pittsburgh to Cornell University and a number of experiments are now being made on belts. In addition to this the other work in progress is as follows:

Standardizing the instrument called "Microcharacter," devised for measuring the comparative hardness of crystals in bearing metals

Comparative properties of bolts with cut and rolled threads

Application of the Midgley indicator to a Continental engine

Investigations on the efficiencies of a 45-hp. Diesel engine operated on various fuels

Properties of lubricants under high pressures and low speeds

Design of a friction test machine to investigate the effect of centrifugal forces on the friction losses

Investigation on the tractive resistance of soils in connection with the use of the farm tractor

The theory of the flow viscometer

Address Prof. H. Diederichs, Head of Department of Experimental Engineering, Sibley College, Cornell University, Ithaca, N. Y.

WORK OF THE A.S.M.E. BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York, N. Y.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval after which it is issued to the inquirer and simultaneously published in Mechanical Engineering.

Below are given the interpretations of the Committee in Cases Nos. 335 and 347 to 350 inclusive, as formulated at the meeting of April 19, 1921, and approved by the Council. In accordance with the Committee's practice, the names of inquirers have been omitted.

Case No. 335

Inquiry: (*a*) Are manhole frames when of the flanged type, considered reinforcing rings and so necessitate their thickness to be at least that of the shell plate, or are they not so considered, so that they can have a thickness less than the shell plate provided their strength meets the requirements of Par. 260?

(*b*) As no method of calculating the strength of flanged manhole frames is given in the Code, would the following method be acceptable? From twice the median line, *ABCDE*, in Fig. 11, subtract twice the rivet-hole diameter and multiply the result by the thickness of the frame and this by the tensile strength.

Reply: (*a*) The thickness of the shell plate referred to in Pars. 259 and 260 is that required by Par. 180 and the thickness and strength of manhole frames and reinforcing rings shall conform to those required for such a shell-plate thickness. When the shell plate is made of greater thickness, such excess thickness shall be given no consideration in the calculations in these paragraphs.

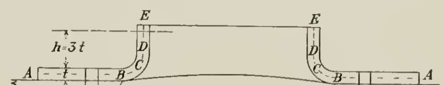

Fig. 11 Cross-Section of Flanged Manhole Frame

(*b*) It is the opinion of the Committee that safe results will be obtained by using as a reinforcement to the ring the flange height (h) up to three times the flange thickness (See Fig. 11).

Case No. 347

Inquiry: Does the requirement of Par. 195 of the Boiler Code for an increase of $^1/_8$ in. in thickness of a dished head fitted with a manhole opening, apply only to concave heads, or to both concave and convex heads?

Reply: It was the intent of the Committee that the increase in thickness of $^1/_8$ in. for dished heads with manhole openings shall apply in all cases whether the heads are concave or convex.

Case No. 348

Inquiry: Would the attachment of a forged-steel manhole neck to a convex head, as shown in Fig. 16, be considered the equivalent of a flanged opening supported by an attached flue and thus be exempted from the requirement for the $^1/_8$ in. increase in thickness specified in Par. 195 of the Boiler Code?

Reply: The manhole neck shown in Fig. 16 is not supported in the sense that it assists the convex head in withstanding the stress due to the steam pressure, and accordingly it is the opinion of the

Committee that it cannot be considered that the head there shown is "supported by an attached flue," and therefore it cannot be exempted from the requirement for the $^1/_8$ in. increase in thickness.

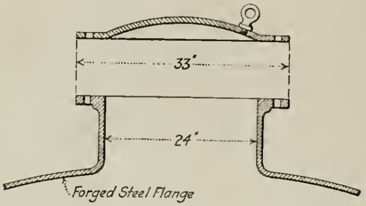

FIG. 16 DISHED HEAD WITH FORGED STEEL MANHOLE NECK

CASE No. 349

Inquiry: Is it permissible, under the requirements of the Boiler Code, in fitting dished heads to the ends of air cylinders or steam drums, to so form the convex head that its flanged edges fit over the outside of the end of the shell, as shown in Fig. 17, instead of within the shell as is usual, in order that a tighter joint may be obtained by calking the edges of the flange to the outer surface of the shell?

Reply: It is the opinion of the Committee that the form of construction proposed is entirely in accord with the requirements of the Boiler Code.

CASE No. 350

Inquiry: Is it permissible, under the rules of the Boiler Code, in fitting different courses of the shell of a boiler at the ends of butt-strapped joints, to weld them together autogenously, in order to avoid the use of plugs or "dutchmen" to render the joints tight?

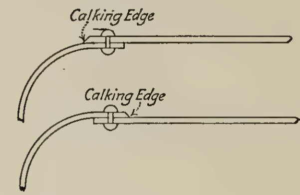

FIG. 17 FORMS OF JOINTS FOR DISHED HEADS IN CYLINDRICAL SHELLS

Reply: It is the opinion of the Committee that if the stress upon the joint is fully carried by the butt straps, the use of welding to render the ends of the joints tight is fully in accord with the requirements of Par. 186 of the Code.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Department of MECHANICAL ENGINEERING are solicited. Contributions particularly welcomed are discussions of papers published in this Journal, brief articles of current interest to mechanical engineers, or suggestions from members of The American Society of Mechanical Engineers as to a better conduct of A.S.M.E. affairs.

Engineering Appraisement

TO THE EDITOR:

Many years have elapsed since the need for the establishment of the value of a property was first recognized. In recent years many conditions have arisen which have necessitated the application of a great deal of engineering skill in properly establishing property values. With the development of the science of appraisement, many technical terms have been introduced for the purpose of explaining the various property conditions which are met with in establishing correct values.

"Property," as the word is commonly understood, may be broadly divided into two classes: one, physical or tangible property; and the other, non-physical or intangible property. Physical property may include such items as land, buildings, machinery, equipment, patterns, drawings, furniture, fixtures, etc. Non-physical or intangible property may include such items as patent rights, trade marks, trade names, good will, business values, etc.

"Value" and "Worth" are nearly synonymous when applied to the inventory of a property. Many conditions, however, are involved in establishing the value of a piece of property. Among these considerations is the use to which this value is to be put, when once determined. In establishing a value of the inventory of a property for insurance purposes, for instance, we have to consider only the present or reproduction value of that property. But if the appraisement is made to establish correct depreciation charges for cost purposes, an altogether different basis of value must be considered.

"Depreciation" signifies a reduction in worth and results, usually, from one or more of several causes. These causes may be, first, wear and tear; second, physical decay; third, inadequacy; fourth, obsolescence.

"Reproduction" Cost, or reproduction value, is the term usually applied to the value which is placed upon an inventory of a property for insurance purposes. In establishing reproduction value, the cost of a machine, as of the date at which the appraisal value is established, must be first obtained. To this must be added an allowance for freight between point of purchase and point of use, and the cost of installation. Reproduction value should never be used as a basis for determining annual depreciation for either cost or tax purposes. "Reproduction value," "cost to replace new," "replacement costs," and "cost of reproduction" are synonymous and are used in reference to an assumed value based on the estimated cost of reproducing the property.

"Cost Value" is the value established at the time used, on the basis of the prices which indicate the actual purchase cost plus freight allowance and cost of installation as shown by the company's books and records. This cost value is subject to a ruling of the Internal Revenue Branch of the Treasury Department which modifies the application of cost values to the extent that where property has been purchased or acquired prior to March 1, 1913, the cost value applied to the appraisement will be the purchase cost as of that date. For all property acquired subsequent to March 1, 1913, actual cost values as shown by the books and records of the company may be used. It is upon this original cost, or purchase value as of March 1, 1913, that depreciation rates are applied in order to determine proper depreciation charges for cost purposes or for tax purposes. Further, it is in the proper establishment of original cost figures and proper depreciation allowances that the careful and scientific appraisement influences the profit showing of the business.

From the standpoint of the engineer, there is probably no other portion of the work involved in making an appraisement which requires more engineering knowledge and skill than that which has to do with the average life of the particular piece of property under consideration. Values may have been properly established, either with respect to cost or with respect to reproduction. Depreciation may have been accurately figured and extensions accurately made. Totals may have been properly summarized and the value of the property carefully shown. All of these elements, however, may grossly misrepresent the going value of a piece of property

if the depreciation study has been improperly made and the average life of a machine has been improperly determined.

No prescribed rule may be laid down to indicate the average lives or depreciation rates of various kinds of property. The Treasury Department recognizes this principle in determining the average life of a piece of equipment under various conditions and kinds of use, in prescribing that the burden of proof as to correct property values and correct depreciation rests with the taxpayer.

After a complete inventory has been made of all of the various classes of property which are to be appraised, and after reproduction costs of these various classes of property have been established, actual cost figures must be applied to the various items as shown on the inventory in order to set up a correct cost value. Idle equipment must be separated from equipment and machinery in use. Depreciation must be applied upon the estimated average life of the particular piece of equipment. Present depreciated costs must be computed by deducting the amount of estimated depreciation from the cost value of the property.

After these various steps have been completed and the appraisal properly summarized to indicate totals of various classes of property by units for insurance purposes and by departments for cost and tax purposes, provision must be made for maintaining a complete record of all purchases of additional machinery and equipment which may take place in the future. For when an appraisal has been properly made and provision has been made for taking care of additions of property, a true record may, with very little trouble, be maintained so that it will show at all times a very close approximation of the cost value of the property as it exists. A proper statement of reproduction values may not be readily established without the assistance of a competent engineer trained in the methods of making such an appraisement.

In establishing the value of a property by means of an appraisal, two broad classes of business may be considered: namely, industrial property and utility property. Utility valuation in recent years has called for a great deal of engineering knowledge and technical skill, and the natural result of the application of this talent in utility appraisement has been to bring it to a high standard of perfection, while up to the time that federal income-tax requirements necessitated a more exact statement of property values, industrial appraisement was not so exacting in its requirements and therefore had not reached the same stage of refinement.

Appraisals may be made for many special purposes, and in the case of the appraisements of utility properties the outright sale of the property or an application for a readjustment of rates for service may be involved. There are five prime purposes for which appraisements of industrial properties may be made: First, for the proper determination of reproduction values for insurance purposes; second, for determining proper annual depreciation charges for cost purposes; third, for determining proper annual depreciation charges for federal tax purposes; fourth, for the determination of invested capital; and fifth, for financial purposes.

In briefly explaining these various uses of a report of appraisement, we will take them up in order as follows:

First, reproduction values of property vary with market conditions. It is therefore necessary to have a property revalued from the reproduction standpoint frequently so that proper and ample insurance protection may be maintained at all times. In the case of a serious fire loss a complete inventory of property is always on hand for adjusting fire losses, and insurance is maintained on an ample basis to cover such losses.

The second use to which a report of appraisement of a property may be put is in determining proper annual depreciation charges for the purpose of making provision for depreciation in charges to production cost. A report of an appraisement should be summarized departmentally, where departmental burden rates are being applied, so that after depreciation charges have been calculated on the basis of original cost or reproduction value as of March 1, 1913, they may be distributed to the various departments within the establishment to which they apply. These departmental values may also be used in connection with the distribution of other fixed charges such as insurance, taxes, etc. It has been the part of good business and the maintenance of a conservative policy in the past to use liberal depreciation rates. The result of this has been to depreciate the purchase cost of equipment in a plant more rapidly than the depreciation has actually taken place. With present conditions, and a heavy tax facing business, in a great many cases it is desirable to revise this past method of applying depreciation, in order to approach more nearly the actual condition. Again, in many cases of old and conservative companies many items of equipment and machinery which may be properly capitalized have been written directly into expense. This procedure naturally eliminates the possibility of applying depreciation to these values and therefore lowers correspondingly the amount of depreciation which may be written into costs and therefore deducted from profits. This condition may be remedied only by means of a proper engineering appraisement.

Third, much the same conditions prevail with regard to ascertaining the proper amount of annual depreciation for federal tax purposes as apply to the requirements of proper cost accounting. Overdepreciation precludes a proper statement of the affairs of a business, and in many cases an overstatement of profits. Charges to expense account of capital items reduce the capital asset account and reduce the amount of depreciation which should have been charged to production cost and therefore deducted from profits. The Internal Revenue Branch of the Treasury Department has placed the burden of proof of a proper statement of fixed assets and proper depreciation charges upon the taxpayer, and each business must therefore show a proper statement of its affairs in order to make a proper return of its income to the Government. Imperfect records of plant accounts preclude the possibility of proper deductions being made from fixed-asset accounts and from depreciation accounts when machines or equipment are sold or otherwise disposed of. Again we have a condition where it is impossible to make a proper statement of fixed-asset values or depreciation amounts without an appraisal.

Fourth, for the determination of invested capital. There are a number of items which may enter into the determination of invested capital. As we have stated, the assets of a business are divided between tangible and intangible assets according to their nature. From the standpoint of tax exemption these are again divided as between admissible and inadmissible assets. In establishing the amount which may be claimed for exemption under the 8 per cent clause of the Treasury ruling, a correct inventory of all plant items must be established. This inventory may also include other items which are usually subject to appraisement, and which may be included as a portion of invested capital. This inventory should be valued at cost prices, and when properly established forms a part of the schedule upon which the amount of invested capital is based. The method of establishing this value differs from that used in the reproduction or usual cost appraisement and requires considerable knowledge of the application of the law.

Fifth, a clear statement of property values in the shape of an engineering appraisement may be very beneficial in cases where additional stock certificates are to be issued, where bonds are to be issued, in the case of mergers or consolidations, in the case of purchase, sale or lease of property, in the extension of bank credit, etc. While it is true that a banker will scrutinize more carefully the current assets and current liabilities than he will the other items on the statement of a business, it is equally true that where he finds a proper statement of fixed assets backed up by detailed statement of appraisal, he will have more confidence in the report of the affair of a business than he might otherwise have. As a basis for making a loan a banker must be able to judge of the potential capacity and productivity of the business. One of the factors to be taken into consideration is the true statement of the valuation of the property. Where many intricate problems present themselves, the skill and technical knowledge of an engineer are required to properly handle these problems.

Chicago, Ill. L. V. Estes.

The *Technical Review*, quoting from *Industritidningen Norden*, states that a Norwegian firm has succeeded in constructing special electric furnaces from which ferrochrome steel free from carbon can be turned out at a cost slightly higher than that of ordinary steel. An English firm has ordered 25,000 tons of the new steel, to be supplied during the next five years.

Lubrication and Hot Bearings

To the Editor:

The editorial by C. H. Norton in the May issue of Mechanical Engineering on the subject of lubrication and hot bearings is very interesting and contains some valuable ideas. However, it appears that Mr. Norton has been unduly influenced by the results of his experiments with a pair of journal boxes and that his final deductions and conclusions may not be safe in their entirety. Nor does it necessarily follow, assuming his data to be correct for a given condition, that they are safe for all conditions of operation.

Mr. Norton has not very completely described the journals and bearings used in his test, and such data as length and diameter of journal, pressure per square inch of projected area thereon when being operated, character and kind of metal used in the bearings—whether babbitt, bronze or brass—are not given. Inasmuch as the behavior of bearings under varying conditions of operation as well as under certain fixed conditions is very largely dependent upon a number of factors other than speed and lubrication, a complete description of bearings under test should accompany the records of results if it is desired that the data resulting from such tests are to be complete.

It is noted that during a test at a speed of 1000 ft. per min. most of the oil was scraped from the journal into the recess. This no doubt shows what may be expected to take place under the conditions obtaining during the test, but so far as the writer can see, there is no similarity between the conditions where a bearing is being continually supplied with oil, as is done in actual everyday practice, and where the oil supplied is managed as was done during the test described.

Regarding the value of oil grooves in bearing shells, it would appear that actual experience has shown that a bearing properly and carefully grooved is safer than one not grooved. So far as the grooves' effecting a reduction in the net bearing surface is concerned, any bearing so limited in wearing surface as not to permit of the cutting of small oil channels will not likely be a safe bearing to use, since any properly proportioned and designed bearing will permit of the use of suitable oil channels and still be liberally on the safe side so far as bearing surface is concerned.

In general, it may be stated that it is better to run any bearing reasonably cool rather than at high temperatures, even though such high temperatures may be considered safe; and, further, even though the internal friction of the oil may be less at the higher temperatures, because of the fact that after a bearing reaches a certain degree of heat only a small additional increase in temperature is required to develop serious trouble, which may result in a damaged bearing and the loss of the machine from service. It may be said also that thin oil for hot bearings is not by any means always the correct oil to use, for it often happens that a medium and sometimes a heavy oil is the only lubricant that can be safely used on bearings to reduce the temperature after they have gotten too warm for comfort.

Atlanta, Ga. C. T. Baker.

Diesel Engines in Kansas

To the Editor:

The fact that the manufacture of Diesel engines has been steadily increasing in the United States may be verified in many ways. One impressive instance that bears out this conclusion is that prominent manufacturers who formerly were engaged in steam-engine construction are now giving more of their time to the production of Diesel engines. One or two cases are reported in which manufacturers have discontinued steam-engine construction and are now devoting their entire attention to the Diesel engine.

In turning to Diesel-engine installations, it would be natural to assume that these were proceeding more or less uniformly, no locality being especially favored. Kansas, however, is a typical locality in which conditions are favorable for their use. Most of the towns in the state are small and well separated, a condition that is favorable to the small central station in each locality. Steam plants find it impractical in most cases to operate condensing because of the scarcity of water, and few of them make any attempt to improve the economy by utilizing exhaust steam for heating purposes. Furthermore, coal prices are comparatively high, and while Kansas is blest with an abundance of fuel oil, its cost for steam generation exceeds that of coal. Kansas could thus be considered a state that would be more than interested in the Diesel engine as a means of better economy in the production of power.

In studying the various installations of full-Diesel engines in Kansas some interesting facts are disclosed. On January 1, 1920, authoritative data show that the total installed rating of the central generating stations in the state was 138,000 kw.; 13.4 per cent of this power was generated by hydroelectric plants, 21.6 per cent was developed by the steam engine, 55.0 per cent by the steam turbine, and 10.0 per cent by gas and oil engines.

Since water power and steam turbines are confined to the large plants in the state, we can reasonably assume that the 21.6 per cent or 41,900 hp. developed by the steam engine and the 10.0 per cent or 19,300 hp. developed by the gas and oil engine are representative of the small central station. If this be true, 32 per cent of the power generated in the state by the small central station is gas or oil power, and 4100 hp. or 21 per cent of this is generated by full-Diesel engines.

To appreciate fully the work that the Diesel engine is doing in Kansas, it is necessary to go beyond central generating service. There are approximately 30,000 hp. of Diesel engines installed in the state for all classes of service. Only 10 per cent of this power is utilized by the small central station, however, the remainder being used in such service as irrigation projects, pipe-line pumping, flour mills, grain elevators and refrigerating plants. The first engine was installed in the state about 1912. Thus, in approximately ten years the total rating in horsepower of Diesel engines has increased so that today it is practically equal to that developed by the state's water power.

Manhattan, Kan. J. P. Calderwood.

Efficiency of Centrifugal Pumps

To the Editor:

The writer was particularly interested in the excellent paper, The Present Trend of Turbine Development, by L. F. Moody appearing in the April issue of Mechanical Engineering. One might, however, take a slight exception, to one of the curves of Fig. 13, namley, Curve *Q*, showing pump efficiencies attained up to the year 1920.

Referring to this curve, the writer would be greatly interested to learn if such high efficiencies as 65 per cent have been obtained with runners of as low a specific speed as 20. If such is the case it certainly is a very remarkable and creditable performance and data on such pumps would prove very interesting as the usual experience with pumps of that low specific speed is rather disappointing and the efficiency is much more likely to be between 40 and 50 per cent than 65 per cent.

A further study of the curve shows that for a specific speed of about 50 an efficiency of 80 per cent might be expected. This, too, is very unusual and much higher than is generally realized for runners of that specific speed; 60 to 70 per cent is more usual and corresponds rather closely to present American practice. It would be of interest to learn whether this curve was plotted from points actually obtained or constructed from theoretical analysis.

It should be stated here that curves as drawn in Fig. 13 applied to centrifugal pumps are a little misleading. The same applies to a lesser degree in regard to water turbines. The reason for this is that the efficiency is not entirely a function of the specific speed alone but is affected to a considerable degree by the capacity for which the pump is designed.

It is possible to design pumps of equal specific speed but of widely different capacities and each will show in general a different efficiency, usually increasing somewhat with the capacity. For this reason a pump having a specific speed of 50 would show an efficiency of 80 per cent only if the capacity were such as would permit it, and in the experience of the writer this is not usually obtained at discharges much less than 3000 gal. per min.

Ann Arbor, Mich. Allen F. Sherzer.

[The foregoing discussion of Mr. Moody's paper was referred to the author, who in reply has submitted the following communication.—Editor.]

To the Editor:

Prof. A. F. Sherzer's discussion of the writer's paper in the May issue on The Present Trend of Turbine Development has been read with interest.

In regard to Professor Sherzer's reference to Curve Q, in Fig. 13 of the paper, showing pump efficiencies, it should be explained that this curve was drawn tangent to the Curve M, representing pump efficiencies up to the year 1911. The latter curve was intended to be reproduced from Fig. 461 on page 603 of Pumping Machinery, by Prof. A. M. Greene, Jr., edition of 1911. The latter curve terminates at a specific speed of about 30, and the curve shown in Fig. 13 has been extended slightly beyond the original point, and in this extended portion does not represent actual results. I agree with Professor Sherzer's remarks regarding the poor efficiencies usually obtained in this part of the pump field. The highest result of which I have any record at hand in this part of the pump field is an efficiency of about 73 per cent at a specific speed of about 34, shown on the upper part of page 603 of Greene's Pumping Machinery.

The great dependence of pump and turbine efficiencies upon the dimensions of the machine has been alluded to in the article. Thus Curve H was stepped up in efficiency from Curve G, to allow for the increase in efficiency obtainable in larger turbines as compared to the small models from which the test results were obtained. As comparison of Curves J and K shows actual results on two turbines geometrically similar, but one of which was about double the size of the other. It is also stated in the article with regard to the generally lower efficiency of pumps as compared to turbines that "much of the difference the writer believes to be attributable to the generally smaller dimensions of pumps," and this point probably counts in some measure for the low efficiencies which Professor Sherzer mentions in connection with pumps of very low specific speeds, since such pumps are seldom built in large sizes.

Professor Camerer has formulated the effect of difference in size, etc., upon turbine performance, in the section beginning on page 299 of his book Vorlesungen über Wasserkraftmachinen (1914), and the same principles would apply to pumps as well as to turbines. The Camerer formula is not strictly correct, for the reason that it assumes all of the loss to be of the nature of pipe or channel friction, thus neglecting the portion of the losses in turbines or pumps due to loss of velocity head in turbulence, eddies, or final discharge. The Camerer method, however, does give us some idea of the effect of change of size upon turbine and pump performance

Philadelphia, Pa. Lewis F. Moody.

Measurement of Energy Used in Impulse Machines

To the Editor:

When considering the problem of arranging a motor for a machine of the impulse type, such as a punch, shear, etc., about the first thing to be determined is how many foot-pounds of energy are used up during each cycle of work. The plants which are fortunate enough to possess the laboratory equipment for determining this are very few in number, and the writer of this article believes that a simple and very accurate method developed and used by him may be of interest to engineers dealing with the problem of motor drives for such machines.

Machines of this class are usually equipped with a flywheel which stores up energy from the motor during the period in which the machine is inoperative, and which gives out this energy to the machine when a clutch is thrown in. Between strokes the flywheel is simply running loose, and if the motive power were shut off, it would gradually be brought to rest by its own friction on its bearings. When stopping in this way its deceleration is constant. The writer has plotted revolutions per minute against time for a number of flywheels coming to rest in this way, and has in each case found a straight-line law. Since the deceleration is constant, we know that the retarding torque is constant, because torque equals moment of inertia multiplied by angular acceleration (or deceleration) and the moment of inertia for any given flywheel is of course always the same. We also know that work equals torque multiplied by angle turned through (in radians), so that if we knew the angular deceleration o a flywheel, and counted the number of turns which it made in coming to rest from any given speed, we could tell the amount of work originally stored in it by the product of moment of inertia × angular acceleration × angle turned through in stopping. This last would be number of revolutions $\times\ 2\pi$. This formula can be more compactly written as $I\ \alpha\ \theta$.

Let us now consider an impulse machine with a flywheel large enough to give the machine sufficient energy to make a stroke. It must be possible to cut off the source of energy from the prime mover at will. This is done most conveniently by a motor with a switch, but other forms can be used. When the flywheel is up to speed, throw out the switch and simultaneously apply a revolution counter to the flywheel shaft. The flywheel wil now stop by its own friction and the number of turns it makes in stopping can be read from the revolution counter.

Now get the flywheel up to speed again and throw in the clutch so that the machine makes a power troke. The switch should be thrown out at the same time as the clutch is thrown in, so that this stroke is made by energy taken from the flywheel. The revolution counter should be applied at the *completion* of the stroke and the number of revolutions made by the wheel in stopping should be noted. Two or three men are of course necessary to perform these operations simultaneously.

If θ_1 be the angle turned through to stop when no stroke is made, the original energy in the wheel is

$$I\ \alpha\ \theta_1 \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

If θ_2 be the angle turned through to stop after a stroke is made, the energy remaining in the wheel is $I\ \alpha\ \theta_2$ and the energy given to the machine is the difference between the two or

$$I\ \alpha\ (\theta_1 - \theta_2 \quad \ldots\ldots\ldots\ldots\ldots [2]$$

We have yet to find α, the angular deceleration. We can get this as we know the original angular velocity of the wheel, which we call ω, from the formula

$$\tfrac{1}{2}\ I\ \omega^2 = \text{original energy in the wheel}$$

which is also given by [1] so that

$$\tfrac{1}{2}\ I\ \omega_2 = I\ \alpha\ \theta_1$$

or

$$\alpha = \frac{\omega_2.}{2\,\theta}$$

Substituting this in [2],

$$\text{Energy given to machine} = \tfrac{1}{2}\ I\ \omega^2 \left(1 - \frac{\theta_2}{\theta_1}\right)$$

This can be written in a more convenient form

$$W = \tfrac{1}{2}\,I\,\frac{(\text{r.p.m.})^2\pi^2}{900}\left(1 - \frac{N_2}{N_1}\right)$$

or

$$W = \frac{I\ (\text{r.p.m.})^2}{182}\left(1 - \frac{N_2}{N_1}\right)$$

where

I = moment of inertia of flywheel
= (weight in lb./32.2) × (rad. of gyration in ft.)^2

r.p.m. = rev. per min. of flywheel when running light between strokes

N_1 = number of revolutions to stop from full speed by friction alone

N_2 = number of revolutions to stop after a stroke has been made by energy in flywheel

W = energy in ft-lb. given to machine in one stroke.

The above formula gives the amount of work given to the machine for one stroke. If we know the number of strokes per minute, we can multiply W by this, divide by 33,000 and get the horsepower. If we have a speed-torque chart of the proposed motor and we know the allowable drop in speed during a stroke, it is obviously quite easy to work out the proper combination of motor and flywheel for any given machine. Of course, *any* flywheel which is large enough can be used for getting the work done during one working stroke.

The writer has used the above method in selecting motor drives for a large number of impulse machines, and has found that, with reasonable care, perfectly satisfactory results can be obtained.

The Need for Research

ARTHUR M. GREENE, JR.

THE word "research" may seem to some to be overworked in these days. When one stops to think of the many thing which have been developed during the last two decades from the results of research, we must realize its importance even more than before. One need only think of the gas-filled lamp, of long-distance telephony, of wireless telegraphy and telephony, of oil cracking, of the air brake, of the modern hydraulic turbine and centrifugal pump to prove what we have said. Many of the new inventions have come as the result of research in pure science where the application was not considered in the research, many have come from investigations to determine the facts for the development of a desired result. In any case the world has benefited; in any case we have extended the frontier of knowledge; in any case we have contributed something to the comfort of man and usually we have conserved nature's energy by more economic applications.

The problems of research which interest the mechanical engineer and which require solution are very numerous, and a few which are receiving the attention of the Research Committee of the A.S.M.E. will be mentioned in this short statement.

Few realize the great loss resulting from the inefficient use of gasoline in an efficient engine. The mechanical engineers of Great Britain have made several valuable reports on the gas engine and its action, and from these our knowledge has been greatly extended. The United States Bureau of Mines has very recently made an investigation of automobile action for the purpose of obtaining data for the proper ventilation of the new vehicular tunnel under the Hudson River at New York. This investigation has shown the inefficiency of the mixing devices used on the engines and points clearly to a great saving by careful and continuous inspection of the exhaust gases from the engine and adjustments of carburetors. The investigation points to the possibility of a development of some other type of mixing device to secure proper proportions of gas and fuel.

The use of steam at high pressure and high superheat in the new or projected power houses calls for a further study of the properties of saturated and superheated steam, as there are differences in these regions which must be harmonized. The research must be faced with absolute integrity and with no bias. Personal, reactional or commercial prejudices must be completely removed and the truth aimed for.

The researches devoted to the elimination of waste from friction are important, as this is present in all moving machinery. Two special committees of the Society are at work on this matter, one endeavoring to study lubricants and the other bearing metals. What are the peculiar properties of oils which reduce friction? What are the properties of metals which make a good bearing metal? Why is the friction loss what it is? The answers to these questions will help us reduce this great source of waste.

Meters for the measurement of flow of fluids have been known for many years, but the peculiar features of installation and maintenance, the limitations of different types, the proper care in operation and the correct theory underlying various types have not been stated clearly and collectively. A special committee of our Society is caring for this matter, and their preliminary report will appear at the Annual Meeting. At the present time they are engaged in studying the problem of pulsating flow.

The rupture of marine shafting subject to driving forces which do not stress it excessively, is due to the fact that the force is a periodic one and vibration is set up. The special committee of research on this subject is taking up another phase of research in collecting all information relating thereto and presenting it to the Society for the benefit of the profession. They will present it in a form which may be of use to the engineer—not only do we need investigation of natural phenomena but the work of research includes the presentation of complete data when this is scattered through technical literature extending over years.

Another phase of research for the mechanical engineer is that undertaken by our Mid-Continent Section, the investigation of the commercial development of industries near the supply of raw materials or near the points of consumption for the purpose of eliminating transportation costs and consequent waste.

The preliminary report of the Committee on the Elimination of Waste in Industry of The Federated American Engineering Societies represents another research of the mechanical engineer. This study has revealed many surprising facts not known before, and even facts which are contrary to accepted beliefs of the past. This mention is made to call attention to this type of research.

What can the profession do to help in this great activity?

First, we should insist on having data for our work. When not known we should investigate and determine the data.

Second, we should be willing to give our data to the profession after we have used it for our development work. Many data are buried where they are doing no work and their publication would not damage our business and would help the proiession.

Third, financial support can be given to those who are equipped to work for the profession in securing data as the result of research.

ARTHUR M. GREENE, JR.

The Waste Report

AS this issue of MECHANICAL ENGINEERING reaches the reader, the edited manuscript of the report of the American Engineering Council Committee on Elimination of Waste in Industry will be ready for the printer. Advance information indicates that the report will be notable for its contents, for the development of fundamental methods for evaluating waste, for the speed with which it was executed, and for the wonderful spirit of coöperation and sacrifice evidenced by the members of the Committee and the managers of the industries considered in the document. In itself it is an example of what can be done with a purpose, a plan, a schedule, and the highest type of unselfish team play.

The Committee proposed to analyze industrial waste, evaluate it, ascertain the causes and suggest measures for getting rid of it. One fact should be constantly borne in mind, however. The report is but preliminary in character, and this has been emphasized again and again by the Committee. It is the message brought

back by a reconnoitering party sent out to determine the best points for a concerted attack on waste in industry, the national economic problem of great magnitude. As expressed by one member of the Waste Committee, it corresponds to the preliminary assay of the metallurgist, the preliminary survey of the civil engineer or the estimate of the designer, all of which must be completed and digested before the actual engineering work can be started.

To conform to this avowed purpose it was important to obtain concrete information quickly. The work actually began on January 3, 1921, and five months later the findings were submitted to the American Engineering Council. The printed report will give the results obtained from intensive investigations of 75 plants in 5 industries, (Building trades, men's clothing, shoe manufacturing, printing and metal trades) and extensive reports on unemployment, strikes and lockouts, sales and purchasing policies, and health and accidents.

After thorough investigation the Committee, to its great surprise, found that there was no standardized method of analyzing and evaluating waste. The first duty was therefore to determine upon an analysis procedure and to set up standards by which waste might be measured. Arduous work was required, but the resulting method, which will be described in the report, is a monument to the Committee's efforts.

In its endeavor to determine the cause and place the responsibility for waste, the Waste Committee faced a severe problem. Obviously waste is not waste unless its wastefulness is known and appreciated. Responsibility for waste cannot be accepted by any individual or group if the waste itself is not acknowledged. The greatest value of the report, therefore, will be its indication of the whereabouts and extent of waste and its assignment of responsibility for waste elimination. This is a far different thing from assigning responsibility for the waste itself.

We can look forward, therefore, to the appearance of a document which will point out broadly the wastes in industry, evaluate them according to a scheme developed by the Committee, and definitely assign the responsibility for their abatement. The elimination of industrial waste is a fundamental requisite for the advancement of our civilization and the work started so ably by the Committee must be carried on coöperatively by commercial, industrial professional and technical societies and associations.

As the society of the industries, The American Society of Mechanical Engineers will devote its entire 1921 Annual Meeting program to the main topic of the Elimination of Waste in Industry, and each of its Professional Divisions will hold sessions which will treat of some definite technical phase of the problem in a thoroughly constructive way. This will be the first organized attack on the waste problem.

Dr. A. E. Kennelly the First French Exchange Professor

The scheme of regular annual exchange of professors between individual universities in France and the United States in academic fields has been extended into engineering and applied science. After negotiations started by Dr. MacLaurin of Massachusetts Institute of Technology in 1919 and consummated finally through the Institute of International Education, a relationship has been established between the French University Administration and a committee representing seven American institutions which goes into effect in the fall of 1921. The French have selected for their first representative, Professor J. Cavalier, rector of the University of Toulouse, and a well-known authority on metallurgical chemistry. He will divide his time during the ensuing academic year among the seven coöperating institutions, namely, Columbia, Cornell, Harvard, Johns Hopkins, Massachusetts Institute of Technology, Pennsylvania and Yale. Although it would have been impracticable to have included a larger number than seven in the American plan, yet it is hoped that other institutions may also derive benefit from the incoming French professor's visit.

The American representative will be Dr. A. E. Kennelly, professor of electrical engineering at Harvard University and the Massachusetts Institute of Technology. Dr. Kennelly has already left for Europe.

The methods of teaching engineering and applied science vary widely in the two countries and the increase in mutual understanding of each other's ideals and viewpoints will be especially fruitful in broadening the engineering profession of America. It is hoped that the plan will operate favorably and lead to an exchange of advanced students to further increase mutual study and mutual friendship.

Eugene Schneider Awarded John Fritz Medal for 1922

The John Fritz Medal for 1922, awarded to Charles Prosper Eugene Schneider, distinguished French engineer and scientist, for "achievement in metallurgy of iron and steel; for development of ordnance, especially the 75-mm. gun, and for notable patriotic contribution to the winning of the war," was presented to him at a meeting of American and British engineers in Paris on July 8.

M. Schneider heads the great Creusot engineering and steel works and shipbuilding plants of France, which with their subsidiaries have 100,000 employees. The remarkable achievements of France in the steel industry during the war were due largely to the genius and energy of Eugene Schneider and his associates in Le Creusot Steel Works. Within two and one-half years France nearly tripled the number of her blast furnaces and increased the number of her open-hearth furnaces by 60 per cent. During the war she increased her production of rifles 290-fold, of machine guns 70-fold, of 155-mm. shells 225-fold, and of 75-mm. shells beyond reckoning.

M. Schneider not only has led in the technical and commercial development of the great and varied steel and other engineering industries of France, but has also given effective attention to the well-being of his men and their families. His schools for workmen, foremen and engineers are among the best in the world. As early as 1877 his company introduced a pension system, antedating similar action by the French Government. He has done much to raise the standards, broaden the outlook and bind the loyalty of his men.

M. Schneider is a member of a number of French clubs and societies. He has received many honors in his own and of the countries for his achievements, among these being the award or the gold medal of the Mining and Metallurgical Society of America, presented to him in 1919.

Dr. Ernest Fox Nichols New President of M. I. T.

The Massachusetts Institute of Technology has selected Dr. Ernest Fox Nichols to succeed the late Dr. Richard C. MacLaurin as president of that institution. A close personal friend of Dr. MacLaurin, he is a full believer in the theory first enunciated by the latter that an engineering school is not doing its complete duty to itself unless it establishes the closest possible relations with the industry of the country. Under Dr. Nichols' guidance, therefore, M. I. T. will continue its plan of organized service to industry.

Dr. Nichols was born in Leavenworth, Kan., in 1869, and was graduated from the Kansas Agricultural College in 1888. He spent several years at Cornell University as a graduate student in mathematics and physics, receiving the degree of master of science in 1893 and doctor of science in 1897.

From 1892 to 1898 Dr. Nichols occupied the chair of physics and astronomy at Colgate University, during which time he was granted leave of absence of more than two years which he spent in study under Professors Planck and Rubens, at the University of Berlin. He was co-author with the latter of Certain Properties of Heat Waves of Great Wave Length, a research which gave physicists new methods of attack. While making this research he devised a new form of radiometer which he later used in this country in measuring the heat from the stars and planets.

In 1898 Dr. Nichols was appointed professor of physics at Dartmouth College, where he remained for five years. During this time he, with his assistant, Assistant-Professor Hull, discovered the pressure of a beam of light, and made accurate measurements of this force.

After a year as professor of experimental physics at Columbia University, Dr. Nichols went to England to lecture at the Royal Institution in London and the Cavendish Laboratory of Cambridge University. In 1905 he resumed his professorship at Columbia, remaining there until 1909, when he was appointed president of

Dartmouth, a position which he held for seven years. From 1916 to 1920 he was professor in physics at Yale. For the past year he has been director of the physical research at the Nela Park Laboratory of the National Electric Lamp Association, Cleveland.

Dr. Nichols has received honorary degrees from a number of colleges and is the author of many articles on scientific subjects.

Arthur M. Greene to be Dean of Enlarged School of Engineering at Princeton

During Commencement at Princeton University it was announced that the trustees of the University have planned to enlarge its School of Engineering for the purpose of giving courses in mechanical, chemical and mining engineering, in addition to those in civil and electrical engineering which have been offered for some years past. These courses will extend over four years, at the end of which time the bachelor's degree will be given. A fifth year will be required for an engineering degree. The plan of the school is one which will not compete with those of engineering schools giving a four-year course, the intention being to make each of the courses mentioned such that the student will secure sufficient engineering training in four years to become an assistant to an engineer, and so be self-supporting, and in addition receive a thorough grounding in physics, chemistry, mathematics, languages, literature, philosophy, economics and sociology to give him a broad outlook on everyday problems. The endeavor will be to make an engineer rather than a specialist.

The fifth year is to be devoted primarily to engineering subjects, including certain courses in engineering economics and possibly a limited amount of research.

Prof. Arthur M. Greene, Jr., of the Rensselaer Polytechnic Institute, has been called to become the dean of the new school and professor of mechanical engineering; he will take up his duties in the fall of 1922.

Professor Greene was born in Philadelphia. He was graduated from the University of Pennsylvania in 1893, receiving the degrees of M.E. and D.Sc. from that institution in 1894 and 1916, respectively. From 1894 to 1907 he was successively instructor in Drexel Institute, instructor in mechanical engineering at the University of Pennsylvania, and professor of mechanical engineering at the University of Missouri, where in 1906 he was Junior Dean of the School of Engineering. In 1907 he was called to the professorship of mechanical engineering at the Rensselaer Polytechnic Institute, where he planned, equipped and developed the present mechanical engineering laboratory. He also planned and equipped new mechanical laboratories at the Universities of Pennsylvania and Missouri.

Professor Greene has served as manager and vice-president of The American Society of Mechanical Engineers and at present is chairman of the Research Committee of the Society, a member of the Boiler Code Committee and chairman of its Special Committee on Steam Piping. He is one of the Society's representatives on the Engineering Division of the National Research Council and on the Executive Board of The Federated American Engineering Societies. He is a past-president of the Society for the Promotion of Engineering Education and the Society of Engineers of Eastern New York, a fellow of the American Association for the Advancement of Science, and a member of The Franklin Institute. He is the author of a number of important treatises on mechanical engineering subjects.

Bradley Stoughton Resigns Secretaryship of A.I.M.E.

After having discharged the duties of Secretary of the American Institute of Mining and Metallurgical Engineers since 1913, during which period the Institute has greatly grown in numbers and influence, Bradley Stoughton has resigned from this office in order to be at liberty to take up other professional activities.

Mr. Stoughton was graduated from Sheffield Scientific School in 1893, with the degree of Ph.B., and from Massachusetts Institute of Technology in 1896 as S.B. He was instructor in the latter institution the following year, and in 1897 became assistant to Prof. H. M. Howe at Columbia University. He was metallurgist for the Illinois Steel Company at South Chicago, Ill., during 1898–1899; chief of the cost statistical division of the American Steel and Wire Company, Cleveland, in 1900; and manager of the bessemer steel department of Benjamin Atha and Company, Newark, N. J., in 1901. From 1902 until his assumption of office in the A.I.M.E. he was in business as a consulting engineer. He was a member of the general engineering committee of the National Council of Defense in 1918–1919. He was for a time head of the metallurgical division and later vice-chairman of the engineering division of the National Research Council.

Mr. Stoughton is a member of the American Iron and Steel Institute, The Iron and Steel Institute (England), the American Society for Testing Materials, International Association for Testing Materials, and the American Electrochemical Society; a trustee of the American Civic Alliance; and a member of the Executive Committee of the N. Y. Association for Relief of the Blind. He is also a member of the Engineers' and Technology Clubs of New York.

He is the inventor of a converter for making steel castings, and a process for oil melting in cupolas. In 1908 he wrote a treatise on the Metallurgy of Iron and Steel which is a standard work on this subject.

Mr. Stoughton brought to the position of secretary a rare combination of abilities not only as a teacher, a designer, an inventor and a writer, but as a forceful speaker on all occasions, and he had an acquaintanceship with the best minds in the world, which he has greatly extended while secretary.

In accepting the resignation of Mr. Stoughton, the Board of Directors of the Institute issued the following words of appreciation:

> The Board of Directors of the Institute, having accepted with regret the resignation of Mr. Bradley Stoughton as Secretary, would put upon record its appreciation of his long and very efficient service to the Institute and further of his willingness to postpone an actual severance of relations with us until it may be convenient for the Board to elect a successor and even until such successor shall have had an opportunity of becoming acquainted with the details and routine of the office.
>
> The Board recognizes the fact that the duties of the office of Secretary have been greatly increased since Mr. Stoughton's first acceptance of this office eight years ago. Our membership at that time—in 1912—was 3500; today it is about 9900, which fact alone means a greatly increased correspondence. While Mr. Stoughton's predecessors in this office were not frequently called upon to travel, excepting upon the occasion of meetings outside of New York City, under the policy introduced some years ago of visiting the Local Sections or having the Institute adequately represented at the meetings of other scientific bodies, Mr. Stoughton has been called upon to travel, and the Board is pleased to believe that in his bearing and in his speeches he has worthily represented the Institute and has enhanced its appreciation among our many members who, for one reason or another, are not able to visit the headquarters frequently.
>
> The Board of Directors expresses the hope that in a new field of activity Mr. Stoughton may have the great success which his abilities deserve, and would put upon record its appreciation of the self-sacrifice with which he has devoted himself to the interests of our organization at the expense of his own professional preferment or financial advantage.

Franklin Institute Awards

At a meeting of the Franklin Institute held on May 18, 1921, honorary membership was conferred upon Gen. John J. Pershing and Frank J. Sprague, consulting engineers of New York City. Mr. Sprague was also presented the Franklin medal for his achievements in electric traction. He was the pioneer of the modern electric railway, inventing the multiple-unit system of electric train control, the constant-speed electric motors, the system of automatic braking train control, etc. He also inaugurated the high-speed electric elevator.

Another recent award of The Franklin Institute is that of the Edward Longstreth Medal of Merit to Jacob M. Spitzglass, vice-president and consulting engineer for the Republic Flow Meters Company, Chicago, Ill., "in consideration of the novelty of recording electrically the flow of liquids in pipes and the mechanical simplicity and excellence of this measuring apparatus." A description of the meter developed by Mr. Spitzglass was given by him in a paper presented before The American Society of Mechanical Engineers in 1919 and printed in the May 1919 issue of Mechanical Engineering, page 429.

William B. Cogswell Dies

William B. Cogswell, founder of the Solvay process and manager and vice-president of the Solvay Process Co., Syracuse, N. Y., died at his home in New York City on June 7, 1921. Mr. Cogswell was born in Oswego, N. Y., on September 22, 1834. He received his early education at Hamilton Academy and at a private school conducted by Professor Root of Syracuse. He completed his education at Rensselaer Polytechnic Institute, from which he was graduated in 1851.

For three years after leaving school Mr. Cogswell se·ved as an apprentice in a machine shop in Lawrence, Mass., and was then for a few years connected with a railroad as superintendent of machinery. In 1859 he became superintendent of the Broadway Foundry, of St. Louis, and in the following year organized the firm of Sweet Brothers & Co., Syracuse, which later became the Whitman & Barnes Manufacturing Co.

During the Civil War he was rated as a mechanical engineer in the Army and later was retained by the Franklin Iron Works to superintend the construction and operation of blast furnaces in Oneida County, N. Y. From 1874 to 1879 he was in the mining business. Three years later he became interested in the manufacture of ammonia soda. He went to Europe to make a study of the soda industry and was commissioned by Solway & Co., Belgium, to locate a plant in the United States in 1891. Through his efforts the Solvay Process Co. became famous.

Mr. Cogswell was a member of over a hundred scientific societies, social organizations and clubs, among which may be mentioned the American Academy of Arts and Sciences, the American Institute of Mining Engineers, the American Society of Civil Engineers, the American Chemical Society, N. Y. State Chamber of Commerce, Sons of the Revolution, and the Colonial Society of America. He belonged to many social clubs in New York City and in Syracuse.

He became a member of the A.S.M.E. in 1880 at the time of its organization and served as one of the managers until 1882.

Death of Charles Maples Jarvis

Charles Maples Jarvis, for some years president of the American Hardware Corporation, New Britain, Conn., and for 22 years before that prominently identified with fabricated steel work, died on May 21, 1921, after an illness of two years. Mr. Jarvis was born on April 16, 1856, at Deposit, Delaware County, N. Y. He was graduated from the Sheffield Scientific School of Yale University in 1877 as a civil engineer. He then entered the employ of the Corrugated Metal Co. East Berlin, Conn., as engineer and draftsman. Later he became chief engineer and president of the company and on its absorption by the American Bridge Co. became a director of the latter as well as a vice-president and member of the executive committee. He retired when the company became a subsidiary of the U. S. Steel Corporation. Mr. Jarvis became a member of The American Society of Mechanical Engineers in 1890 and served as vice-president from 1897 to 1899.

Death of Samuel E. Tinkham

Samuel E. Tinkham, connected since 1874 with the engineering department of the City of Boston, Mass., and with its successor, the Department of Public Works, died on April 21, 1921. Mr. Tinkham was born on March 3, 1852, in Taunton, Mass. He was graduated from the Massachusetts Institute of Technology in 1873 in civil engineering and began work in the engineering department of Boston in 1874. In 1914 and 1915 he was acting division engineer of the bridge and ferry division of the Department of Public Works of Boston, and later became engineer of construction of the division. He was prominently connected with the management of the Boston Society of Civil Engineers for more than forty years and was its secretary from 1880 to 1882, and again continuously from 1887 to date. He also belonged to various fraternal, patriotic and social organizations.

U. S. Industrial Waste Commission Proposed

A bill intended to continue and to amplify the survey of the elimination of waste in industry, made by the committee of the F.A.E.S., has recently been introduced in Congress by Senator Calder. The bill provides for the presidential appointment of a United States Industrial Waste Commission consisting of the Secretary of Commerce as chairman and six others, who shall make a study of waste in the utilization of the available supplies in the United States of timber, power, transportation, oil, coal, and essential minerals, and shall recommend improved methods for their utilization. The Commission is also to recommend measures for elimination of intermittent and seasonal production and of national waste. It is to serve without compensation, adopt its own plan of procedure and submit its report to the President on or before Sept. 1, 1922.

John Crerar Library in New Home

The John Crerar Library, Chicago, first opened to the public in 1897, has recently moved into its new building at the corner of Michigan Avenue and Randolph Street. This library is a free public reference library of scientific and technical literature, endowed and maintained by a bequest of John Crerar, a prominent business man of Chicago who died in 1889. At the time of its first opening it had 15,000 volumes ready for use and 7,000 more in the hands of cataloguers. Its report for 1920 shows a total of over 425,000 volumes and 177,000 pamphlets and over 4000 periodicals currently received. Its property is valued at nearly $6,000,000 and it was used during 1920 by nearly 50,000 people despite the fact that it was closed for four months of the year during removal. It is estimated that the property on which the new building is located will provide for the needs of the Library for 150 years. The dedication took place on May 28 and was attended by representatives of various scientific and technical societies.

U. S. Patent Office Relief

The Lampert bill for Patent Office relief has been reported out favorably in the House and the House Committee on Rules will probably make a special rule for hastening its passage. The federal trade commission section which was incorporated in the Nolan bill and which prevented its passage in the Senate in the last session, has been omitted from the present bill, which otherwise closely parallels the Nolan bill.

The Lampert bill provides for about fifty additional employees in the Patent Office at Washington and for an increase of approximately $500,000 in the Patent Office appropriation. This will greatly relieve the serious condition due to the resignation, on account of inadequate compensation, of over 100 examiners and over 150 of the clerical force in the past sixteen months. On account of this shortage of employees, work in the Patent Office has been greatly delayed so that some 46,000 applications for patents are now pending and work throughout the office is months behind.

Under the Lampert bill there will be increases in the salaries of the examiners, commissioners, and clerks ranging all the way from $150 to $2300, according to the character of the work performed, and there will also be various modifications in procedure made necessary by changing conditions during the last few years.

Registration at Engineering Colleges in U. S.

A census of the registration at engineering colleges throughout the United States was recently made by *Engineering News-Record*. Returns from 81 institutions located in 36 states show a total registration for the college year 1920–1921 of 48,312 students in all engineering courses as against 46,395 for the previous year. There has been, therefore, a gain of 4.1 per cent. The figures reveal that mechanical engineering is the most popular of the engineering courses. This year 12,159 students were registered in mechanical engineering and last year 11,693, a gain of 466. Electrical engineering runs mechanical engineering a close second, the figures for this year and last year being respectively, 12,118 and 11,285, or a gain of 833. Civil engineering comes third with 8592 undergraduates this year and 8469 last year. Chemical engineering, with about 6500 students for the past two years, takes fourth place, while the mining engineering course, in fifth place, shows a considerably smaller registration than any of the others.

News of the Federated American Engineering Societies

A.E.C. Sends Resolution of Thanks to A.S.M.E.

The following resolution to the officers and members of The American Society of Mechanical Engineers has been received from American Engineering Council's Committee on Procedure, acting for the Executive Board of the Council:

Whereas, The members and officials of the American Society of Mechanical Engineers manifested great interest and gave unsparingly of their time and effort to the preliminary arrangements and meetings leading to the organization of The Federated American Engineering Societies; and

Whereas, The office facilities and clerical force of The American Society of Mechanical Engineers were made available and extensively used by officers of The Federated American Engineering Societies during their organization period; and

Whereas, The executive and administrative officers of The American Society of Mechanical Engineers were always most attentive to every request for advice and help; be it

Resolved: That the Executive Board of the American Engineering Council in behalf of The Federated American Engineering Societies hereby express the deep appreciation of the engineering fraternity for the valuable, efficient and effective help which has been rendered by The American Society of Mechanical Engineers.

Elimination of Waste Report Made Public at Executive Board Meeting on June 3

THE fourth meeting of the Executive Board of the American Engineering Council was held at St. Louis on the first anniversary of the Organizing Conference which met in Washington on June 3, 1920. As a result of invitations to the leading engineering organizations in the vicinity of St. Louis, a number of representatives of these bodies were present at the meeting.

The outstanding feature of the meeting was the presentation and consideration of the preliminary summary of the report of the Committee on the Elimination of Waste in Industry. This was fully discussed and the report referred back to the Committee for publication. The Committee on Procedure was authorized to accept the offer of The American Society of Mechanical Engineers to arrange for the publication of the complete report in book form. Announcements as to when and where copies of this report may be obtained will be made later.

Upon the recommendation of the Committee on Membership and Representation the following organizations were admitted to charter membership in the Federation: Iowa Engineering Society, Jamestown Engineering Society, and American Society of Safety Engineers. Under the constitution the opportunity of coming in as charter members expired on July 1, but considerable sentiment has developed in favor of extending the time for this purpose and as a result the Executive Board has decided to bring the matter before the next meeting of the American Engineering Council, to be held in January 1922.

Following a discussion as to the possibilities of coöperation between the Federation and the American Association of Engineers, L. W. Wallace, Dexter S. Kimball, and Calvert Townley were appointed a committee of three from the F.A.E.S. to consider this matter with a committee of three to be appointed by the Board of Directors of the A.A.E. The committee was not given any specific instructions. It is to report its findings to the Executive Board.

Among the recommendations of the Public Affairs Committee which were given the approval of the Executive Board were the following:

That no action should be taken in legislation pertaining to the Federal Power Commission; and

That the American Engineering Standards Committee plan for obtaining coöperation with Government departments be sanctioned.

The Committee on Licensing submitted a report containing its new recommendations on the uniform law. After considerable discussion it was decided to send the report back to the committee with the request that a hearing be held at which all interested may have an opportunity to speak and that following this hearing the report be redrafted so that it may receive further detailed consideration at the next meeting of the Executive Board—to be held sometime in September.

The Board approved support for the present bill in Congress to give increased assistance to the topographic mapping program recommended by the Board of Surveys and Maps, on which L. W. Wallace is serving as representative of American Engineering Council.

The recommendations concerning coöperation with the Personnel Research Federation were carried over for further consideration and the question of representation on the National Conference Board of the Building Industry was referred to the Committee on Procedure with power in the event that this matter should again be brought up. Upon recommendation of the Committee on Procedure, J. P. Healy, of Washington, D. C., was appointed alternate to Rudolph P. Miller on the National Board of Jurisdictional Awards in the Building Industry.

The Committee on Foreign Relations reported that it had participated in the reception and entertainment of delegations of Italian and French engineers visiting in this country. A resolution to British engineers expressing admiration for their effective work during the war, and sympathy for the sacrifices in life, health, and property which their services involved, was approved by the Board and a special committee was appointed to draft a similar resolution to French engineers.

Important Amendment to U. S. Patent Laws Proposed

Legislation to require the compulsory working in this country of patents issued to or controlled by nationals of foreign countries has been brought to the front by the introduction of Senate Bill 1838, which carries the following amendent to that section of the patent statutes which deals with the patenting in this country of inventions previously patented in a foreign country:

> Any patent or patents issued to a person or persons not citizens of the United States shall contain a proviso to the effect that if such patent so granted is not worked or put in operation so as to result in actual production of the article in reasonable quantities embodied in such patent in the continental limits of the United States within the period of two years from the date of its issue, the United States reserves the right to license any person or persons for purposes of manufacture in the United States, and to use and sell the subject matter thereof.

The amendment subjects this provision to a further provision empowering the Commissioner of Patents to determine a fair royalty to be paid the foreign owner of the patent by the licensee in consideration of the license.

Under the present patent system, a foreign inventor has the right to manufacture, use and vend his invention in this country for seventeen years. But as each of these rights is a separate entity, inventors can take advantage of the economic conditions prevailing in foreign countries and manufacture their inventions in their own countries at less expense than in United States. Even the expense of transportation and import tariffs do not usually increase the cost to such an extent that it would be more economical to manufacture the invention in this country. It has therefore become almost universal practice for a foreign owner of a United States patent to manufacture the invention in his own country, and then take advantage of his right to its sale in the United States.

Supporters of the amendment state that by granting to a foreign inventor the exclusive right to sell his invention in this country entirely independent of the requirement that it also be manufactured in this country, the United States patent laws foster the development of foreign industries and retard the development of our own. An example cited is that of the dye industry, in which practically all developments are held by German inventors or their assignees. While the United States is one of the large users of dyes, her dye industry has not prospered, by reason of the German-held United States patents, while the dye industry in Germany has grown enormously.

On the other hand, there is strong opposition to the amendment by those who point out that it would have a tendency to force the

working of patents in this country which are owned by foreign capital, defeating Americam manufacturers who are trying to make this country independent of, for instance, the German dye and other industries. For if the foreign-owned American patent were of sufficient value to warrant competition here, its owner would be willing to comply with the provision, rather than allow the manufacturing rights to pass into American hands. But if it were an unimportant patent he would lose little and the United States gain little if the patentee failed to comply with the compulsory working provision.

It is further argued that to enact a compulsory working clause applicable only to foreign owners of American patents might easily pave the way for such a clause applicable to all United States patents, even though owned by American citizens. The objections to such a situation are so apparent as to need no enumeration.

The amendment is undoubtedly an extremely important piece of legislation, affecting both the tariff system and foreign relations, and merits the careful attention of all interested in the protection and development of the United States industries.

This amendment, which is known as the Stanley bill, was inaugurated by the War Department and is intended to apply especially to war materials. The Senate Committee on Patents has recommended its immediate passage without amendment.

Licensing of Engineers in New York State

Frequent inquiries as to the working of the New York State Engineers' License Law, passed May 14, 1920, and amended May 6, 1921, have resulted in the publication of the following brief summary covering the chief provisions of the law.

No engineer unless licensed may legally practice professional engineering or land surveying after May 6, 1923, that is, two years after the date the law was amended.

In a corporation, partnership, or joint stock association engaged in the practice of engineering the engineer in responsible charge of the work must be licensed. Subordinate engineers who report to such an engineer need not necessarily be licensed. It is to be hoped, however, that the prestige of a license will be such that all engineers who are eligible for license will apply for one.

Some exemptions are allowed non-resident engineers practicing in New York State. No license is required for:

1 Offering to practice when having no established place of business in New York State
2 Practicing when having no established place of business, provided such practice does not aggregate more than thirty days in one calendar year and provided such non-resident engineer is legally qualified for such professional service in his own state or country
3 Practicing professional engineering or land surveying, provided application for license is pending, and fee has been paid. Such exemption to continue only for such reasonable time as is required for granting or denying of application.

Further exemptions are made for engineers practicing as pupils or under the direction of a licensed engineer, or practicing on work solely for the United States Government, and further, practicing solely as an employee of the state from the time act becomes effective until the expiration of the then existing term of office of such employee.

The registration fee is \$25 for a license either as a professional engineer or as a land surveyor, or \$35 if the license be for both combined. The yearly renewal fee is one dollar if made prior to December 31, with a penalty of ten cents for each month's delay in paying renewal, accumulating to a maximum of two dollars.

An Opportunity for Hydraulic Research

Offers which have been made recently to the Engineering Foundation, if supported by financial assistance, will make possible an extensive research in hydraulics. One of the largest hydraulic power companies in America has offered to coöperate with the Engineering Foundation by making its valuable facilities available in any way in which they can be properly used, and an eminent hydraulic engineer has also offered his advice in conducting such a research. To take advantage of this opportunity, the Foundation states that it needs a special fund of not less than \$25,000 a year for a number of years. Further information may be obtained from Alfred D. Flinn, secretary of the Foundation, 29 West 39th Street, New York, N. Y.

NEWS OF OTHER SOCIETIES

National Electric Light Association

Convention in Chicago on May 31 to June 3. The broad aspects of public relations, finance, operation and business were discussed by leading executives and engineers and by public-service commissioners. An analysis of the fundamental economics affecting the service rendered by electric light and power companies was made by Martin J. Insull in his presidential address. Mr. Insull saw the industry in a strong position, but in need of large sums of money to take care of the program of expansion demanded by the public.

Henry J. Pierce, of Seattle, Wash., surveyed the progress made in the utilization of water power in the United States since the enactment of the water-power act in June 1920. Up to the present time 223 applications for preliminary permits and licenses for development of an aggregate of over 15,000,000 hp. have been made to the Federal Power Commission. According to Mr. Pierce, the difficulty of utilizing the hydroelectric resources of the country comes from the fact that 70 per cent of the primary power used for manufacturing purposes is east of the Mississippi River, while 70 per cent of the hydroelectric resources of the country is west of the Rocky Mountains. The total amount of primary power developed and used at present east of the Rocky Mountains for all purposes other than by railway locomotives is 37,000,000 hp. and the total available water power in that region is about 15,000,000 hp., so that if all of this water power available were developed there would still be a shortage of 22,000,000 hp. to be supplied by steam. On the other hand, 40,000,000 hp. can be developed hydroelectrically west of the Rocky Mountains, and but 5,000,000 primary horsepower is now used, of which 2,000,000 hp. is developed by steam and 3,000,000 hp. hydroelectrically. Guido Semenza, head of the Italian railway electrification commission, spoke on the development in the utilization of water power and interconnection of electric plants in Italy. The hydraulic power committee, which was organized at the convention in Pasadena last year, reported the results of its studies on the development of efficient draft tubes, the control of tailwater level, the relation between rainfall and stream flow, evaporation, and the operation of hydraulic plants for maximum output. Surveying recent developments in the utilization of water power, the report mentions the 55,000-hp. turbines designed to operate under 305 ft. head for the Queenston-Niagara station of the Hydroelectric Power Commission of Ontario, and the use of 22,500-hp. turbines under 800 ft. head at the Kern River No. 3 station of the Southern California Edison Co.

A tendency to increase turbine speeds and to improve turbine economy by raising steam pressure was indicated in the report of the committee on prime movers. Single-cylinder turbines seem to be still limited to 45,000 kw. A new record as regards boiler sizes was established by the installation at the plant of the Ford Motor Co. of four boilers each rated at 2647 hp. Pressures and superheats are gradually rising, although 300 to 350 lb. per sq. in. and total temperatures of about 650 deg. fahr. seem to be the highest values being used at present. Information regarding the burning of "hogged fuel" by the Northwestern Electric Co. of Portland, Oregon was included. This fuel shows a loss of from 30 to 40 per cent in B.t.u. content after being in storage for a year, and it makes little difference whether the storage is indoor or outdoor. The use of lignite has not received any great impetus as a result of the acute demand for fuel during the war. However, very complete tests of lignite have been carried on both in the Bitterfeld station in Germany and at the Melbourne plant in Australia, so that the properties of this fuel under various operating conditions, as well as the design features to be embodied in stokers and furnaces, have been clearly defined. Continued interest has been manifested in the pulverized-fuel method of burning coal. High ratings are obtained in new plants where boilers have ample combustion space and are designed expressly for burning pulverized fuel. The Lakeside plant in Milwaukee, designed for burning pulverized fuel, has recently been put in operation and will have an ultimate capacity of 200,000 kw. Processes for the recovery of by-products from raw coal have been developed further in England and Germany than in this country. Attention was called to the fact that The American Society of Mechanical Engineers is revising piping stand-

ards for pressures higher than 250 lb. per sq. in., acting as the sponsor body designated by the American Engineering Standards Committee with a view to adopting an American standard for such pressures. Following the presentation of the report of the committee on prime movers a discussion ensued on the best specifications for lubricating oils and the economy of burning pulverized fuel. W. J. Santmyer, Puget Sound Light & Power Co., stated that with pulverized-fuel plants, efficiencies are obtained which are unbelievable, boilers can be forced to remarkable overloads, and equipment is particularly flexible in operation. He referred to one 500-hp. installation where the boilers could be put on the line and made to carry 300 to 400 per cent rating in 40 minutes. Joseph Harrington, Brady Foundry Co., questioned the economy of pulverizing coal containing more than 15 per cent ash or 8 per cent moisture. Modern stokers, he said, can burn anything from lignite to anthracite coal and have horizontal efficiency curves from 150 to 250 per cent rating, can increase from 150 to 250 per cent rating in three to four minutes, and can burn coal containing 40 per cent ash without clinker formation.

Technical sessions were also held on electrical apparatus, overhead systems, underground systems, electric meters and inductive interference. An exhaustive account of the technical, commercial, and financial features of the convention is given in the *Electrical World* for June 4.

Society of Automotive Engineers

Semi-annual meeting at West Baden, Ind., on May 24 to 28. Sessions were held on aeronautics, highway transport, general research, combustion and fuel research.

A paper by L. E. Pierce and G. J. Mead on Aviation Power Plant Development stressed the necessity of better installations of the power plant to eliminate engine failures in the air. These generally result from minor defects in the operation of the gasoline, cooling or lubricating systems, which are independent of the engine itself. Discussing this paper Elmer Sperry urged the study of the Diesel engine as a possible power plant for the aeroplane of the future, particularly in view of the fact that this type of engine burns a fuel whose low volatility reduces the fire hazard. The present status of commercial air transportation was surveyed by V. E. Clark in a paper entitled Air Transportation and the Business Man. Mr. Clark admitted that no air-transportation project has proved to be a financial success; but he recalled that it was not until 50 years after the invention of the locomotive that railroad investments returned profits and the manufacture of the automobile became commercially successful in 20 years. The aeroplane is now only 12 years old. The Need for Federal Control in Commercial Aviation was discussed by S. H. Philbin, who presented the matter from a legal standpoint.

In Transport Engineering Education, C. J. Tilden emphasized the need of providing a proper curriculum in the universities in order that men could be given an education which would fit them for the practical management of motor-transport companies. The Vehicle and the Road was presented by A. T. Goldbeck of the Bureau of Public Roads. Mr. Goldbeck advocated greater coöperation between the highway engineer and the automotive engineer. He thought that it might eventually become necessary to lessen the weight concentrated on each wheel by increasing the number of wheels in large motor trucks used for highway transport.

C. W. Stratford explained the research work on lubrication that has been done under his direction on the Pacific Coast. W. E. Lay described the plan recently inaugurated at the University of Michigan to place the laboratory and personnel facilities of the university at the disposal of commercial organizations to promote advanced research study. A paper on Practice and Theory in Clutch Design, by Herbert Chase, contained particulars concerning American and British practice in clutch design, and compared the advantages and disadvantages of various types of clutches.

Turbulence in Theory and in Practice, by H. L. Horning, embodied a collection of data from the experimental results obtained by Chatelier and Mallard, Wheeler and Mason, Prof. Bertram Hopkinson, Sir Dugald Clerk, Harry Ricardo, and other investigators, as well as from a large number of experiments conducted under Mr. Horning's observation. By developing high turbulence in a mixture it is possible to drive off the surface layers of the combustion chamber and thus force their full contents to contribute to the heat and pressure before the expansion stroke commences. Turbulence tends to accelerate the combustion of the entire mixture and makes it possible to obtain high speeds without advancing the spark excessively. C. A. French submitted a hypothesis on the action of flame and combustion in internal-combustion engines. A paper by Sir Dugald Clerk on Cylinder Actions in Gas and Gasoline Engines outlined the fundamental thermodynamic theory of the present-day automotive engine.

The possibility of developing a high-compression engine for use in automotive vehicles was discussed by F. C. Ziesenheim. The conclusion reached by Mr. Ziesenheim was that this type of engine should receive careful study as one of the possible factors in deferring the fuel shortage. George P. Dorris described a manifold developed for the purpose of trapping and distilling the higher ends of modern engine fuels, thus preventing their entering the combustion chamber in liquid form. The Elements of Automobile Fuel Economy were enumerated by W. S. James of the Bureau of Standards. Thomas Midgley, Jr., informed the members of the recent discovery of a fuel dope that was more effective in eliminating fuel knock than any used previously. Owing to the effectiveness of this substance only a small percentage need be added to the fuel, and Mr. Midgley felt that by its use higher compressions might be developed in Otto-cycle engines and eventually a thermal efficiency might be secured which would be comparable to that of the Diesel engine.

American Iron and Steel Institute

General meeting in New York on May 27. Business conditions and remedies for the prevailing depression were the chief subjects of discussion. A notable incident was an appreciation by Gen. John J. Pershing of the activities of the iron and steel industry during the war. In his presidential address Judge Gary expressed his views of the present business situation and its difficulties. He felt that the country was now headed in the right direction, and progress toward recovery, though slow at present, would increase in due time. A number of short speeches by leaders of the steel industry upon present business conditions followed Judge Gary's address.

The educational work being conducted by the American Steel & Wire Co., of Cleveland was described by Charles R. Sturdevant. Seven courses have been established: an intensive course for salesmen, a special business English course for general office forces, Americanization courses for non-English-speaking employees, vestibule schools for skilled and unskilled workers, a trades course for upgrading craftsmen, a special apprentice course for a limited number of technically trained men, and a course for foremen and supervisors. The Americanization, vestibule and trades courses are elementary; the courses for salesmen and foremen are intermediate; the student apprentice course is advanced; the business English is a special course and the library is used as an accessory. Admittance to any of the courses is voluntary on the part of the employee, who is not thereby required to sign indentures or agreements to remain with the company after completing the course. Results have been very gratifying.

Harlow D. Savage, Combustion Engineering Corporation, New York, presented a digest of the work that has been done in the last three years in the equipping of steam power plants to use powdered coal as fuel. There are now throughout the United States about ten commercial plants of large size burning pulverized coal. Some of these plants have been in operation for nearly three years. Mr. Savage asserted that with a correctly designed and properly operated pulverized-fuel system it is fair to expect an efficiency of 77 per cent, judging from results obtained in tests and in actual operation of plants.

The composition, properties and uses of stainless steel, and the method of manufacturing this alloy, were explained by Elwood Haynes, president, Haynes Stellite Co., Kokomo, Ind. Stainless steel must contain iron, chromium and carbon, and may contain various other elements, such as manganese, molybdenum, tungsten, silicon, etc. Immunity to atmospheric influences is acquired when the chromium content reaches at least 8 per cent, and the

highest immunity when the chromium content is 11 or 12 per cent. The best results in the manufacture of stainless steel are obtained by means of the crucible or electric furnace. Stainless steel may be forged at temperatures varying from 800 to 1200 deg. cent. and be readily rolled into rods and sheets under proper conditions. By proper annealing, a bar containing 15 per cent chromium can be rendered sufficiently soft to be worked in the lathe, though even when annealed it is much harder than ordinary machinery steel. When thin strips are heated and allowed to cool in the air they become almost file-hard.

A summary of the practical and commercial features of molybdenum steels was presented by Arthur H. Hunter, president, Atlas Crucible Steel Co., Dunkirk, N. Y. Molybdenum steels, compared with other alloy steels in the same category from a commercial standpoint and treated to the same tensile strength, show a slightly higher elastic limit, a higher elongation, and a much higher reduction of area.

Taylor Society

Spring meeting at Cleveland on May 19, 20 and 21. An address of welcome was made by Alexander C. Brown, president of the Cleveland Chamber of Commerce, who enumerated the present national problems, such as business depression and unemployment, and said that one of the dangers of the situation is that the Government may attempt to settle too many of these problems. He declared that one of the functions of the Taylor Society is to focus its attention on many of these problems and do what it can to solve them without the necessity of legislation. Technical sessions were held on sales executives, administrative officers, plant managers, personnel administration and industrial relations.

Howard G. Benedict, consulting management engineer, Cleveland, spoke on performance rating and bonuses for salaried employees. He described a plan he had formerly tried for rating men and setting a money value on coöperation. Each salaried employee was periodically rated by a rating committee with respect to attitude on coöperation, reliability, ability, action, leadership, and personality. Definite elements were considered in rating each quality. For example, reliability was considered as made up of honesty, truthfulness, dependability, straightforwardness and sincerity.

Morris L. Cooke, consulting management engineer, Philadelphia, in a paper on Unemployment Scores suggested the adoption of standards to measure "unemployment within employment," that is, insufficient work to keep employees busy all of the working time. The test of efficiency in management, he said, is the percentage by which the amount of time actually occupied in production work falls short of the possible maximum based on a predetermined proper length of working day.

Carl Snyder, statistician, Federal Reserve Bank, New York, discussed the value of an index number of physical production to administrator and manager. He showed with charts that industrial production in the United States has been moving upward at a uniform rate during the last fifty years. Assuming that there will not be a sudden change, it would seem that, since present underproduction is more striking than overproduction was last year, a violent reaction must soon take place. Production data, he believed, can be developed to a point where it will not be hard to make fairly accurate forecasts, the problem of overproduction of a particular commodity being really one of unbalanced general production. By maintaining elaborate statistics concerning production in all industries, the supply and the demand of any particular commodity could be made to correspond. Another advantage of the regulation of production would be the elimination of violent fluctuations in prices.

At the session on industrial relations a symposium was held on joint action of employees and management in establishing standards, tasks, rates and other standard conditions.

American Society of Refrigerating Engineers

Spring meeting in Chicago on May 25 to 27. Exceptions were taken to the refrigeration code in its present form. One dealt with the pressure at which the release devices for different refrigerating media should be set. Assuming the value given for ammonia to be correct, the pressures listed for ethyl chloride, sulphur dioxide and methyl chloride are too high and should be reduced to correspond with the pressure given for ammonia. The same reasoning applies to other tabulations. A propeller for brine agitation and circulation designed in accordance with formulas developed by O. G. Halvorsen, professor in marine engineering at the technical college at Trondhjem, Norway, was described by E. A. Burrows. In Spray Cooling Systems, P. K. Lindsay brought out the great increase in cooling capacity obtained by the use of sprays over a basin or pond without the sprays, indicated the piping arrangement used and the operating pressure, described the nozzles, and summarized the average cooling results from a well-designed spray system with unrestricted air circulation. Prof. E. A. Fessenden outlined the results of a series of tests on welded ammonia containers. Four types were tested: (1) Flange-steel shell, acetylene-welded longitudinal seam, concave heads welded to shell; (2) seamless-pipe shell, convex heads acetylene-welded to shell; (3) seamless-pipe shell, concave heads forge-welded to shell; and (4) flange-steel shell, acetylene-welded longitudinal seam, convex heads acetylene-welded to shell. Professor Fessenden concluded that vessels with forge-welded seams are the least desirable. Welds joining fittings for pipe connections to the vessel are almost as likely to cause failure as the longitudinal and circumferential seams. In acetylene welds the principal defects seem to be the coarse granular structure and porous spots obtained and the occasional poor adhesion of the welding material to the original plate. A new type of nozzle which gives a hollow, cone-shaped spray was described by S. C. Bloom. Multiple-Effect Compression, by H. C. White, contained a report of comparative tests on a single-acting compressor and a compressor equipped with the Voorhees device. Other papers were: Arc Welding Applied to Refrigerating Machines, by A. M. Candy; Refrigeration in the Manufacture of Rubber, by J. H. Vance; Modern Air-Compressor Practice and Testing, by Harry Feldbush; Water Treatment for Raw-Water Ice, by John J. Felsecker; and Eggshell Sterilization for Cold Storage, by Elmer Anderson.

International Railway Fuel Association

Annual convention in Chicago on May 24 to 26. Committee reports were presented on briquets and subnormal fuels, fuel accounting, pulverized fuel, locomotive feedwater heating and coal storage. Progress in burning pulverized coal in locomotives and in stationary railway plants was surveyed by the committee on pulverized fuel. Tests were made on a locomotive by the Lehigh Valley Railroad to determine the practicability of burning pulverized North Dakota lignite containing 15 per cent moisture and Red Lodge sludge (Montana sub-bituminous coal) without resulting in serious honeycomb formation or unusual disintegration of brickwork. The results were successful with the exception of the honeycomb formation which with either coal developed rapidly on the back flue sheet when the locomotive worked hard and seriously hampered operation. In stationary practice two new plants burning pulverized coal were completed and put into operation during the year, namely, the St. Francis plant of the Milwaukee Electric Railway & Light Co. and the Oklahoma City Plant of Morris & Co. Progress in the simplification of the Locomotive Feed Water Heater Co. and the Worthington feedwater heaters was reported by the committee on feedwater heating. That fuel accounting be handled by the auditing department was recommended by the committee on fuel accounting. Every railroad engaged in interstate commerce is guided in its final accounts by certain rules and regulations laid down by the Interstate Commerce Commission. The accounting department of every railroad understands these regulations and knows how to meet the requirements with regard to the allocation of fuel charges to operating expenses. Some of the technical papers were: Present Railway Situation, by Samuel O. Dunn; Fuel Conditions on the French Railways, by M. de Boysson; Preparation and Distribution of Fuel, by P. E. Blast; Fuel Department Organization by L. G. Plant; and Value of Individual Fuel Performance Records, by Robert Collett. A very complete report of the convention is found in *Railway Age* for May 27 and June 3.

Standard Methods of Identification of Fluids Conveyed by Pipes in Power Houses and Industrial Plants

SAFETY and economy of time in making changes and additions to piping systems demand that in a given layout these systems should be so marked that the liquids or gases passing through them may be readily identified. Many firms have met this need by adopting color schemes of various kinds. In some cases the standard colors are applied only to the valves, fittings and insulation bands, all the pipes being of the same color. In others the color of the pipe in combination with the colors of the valves, fittings and insulation bands is employed to tell the tale.

Since, as is natural, these independent efforts to solve this problem have resulted in the use of a great variety of colors and in an absence of uniformity or standard practice, the American Engineering Standards Committee has been appealed to. After consideration the Committee asked the National Safety Council, Chicago, and The American Society of Mechanical Engineers to act as joint sponsors and to organize a Sectional Committee for this purpose. The members of this Committee are now being selected.

As a result of some recent and previous correspondence the A.S.M.E. Standards Department has gathered together some specific information concerning four systems in addition to the one recommended by an A.S.M.E. committee in 1911. The principal parts of these systems are printed below. A superficial examination of this table will, however, convince one that even though it is long it does not include all the fluids which are in common use in many laboratories and manufacturing plants. A few of the missing ones are oxygen, hydrogen, acetylene, natural gas, and lubricating liquids. It is also probable that acid-manufacturing plants have other materials which must be conveyed by pipe lines.

It can be readily seen, therefore, that with such a variety of materials to be conveyed, the problem of selecting a standard set of color combinations for easy and sure identification will not be an

VARIOUS COLOR SCHEMES FOR IDENTIFYING PIPES IN POWER HOUSES AND INDUSTRIAL PLANTS

Fluid to be Identified in Pipe	Report of A.S.M.E. Committee 1911	The New York Edison Company	Kodak Park Piping	University of Toronto	Westinghouse, Church, Kerr & Company
	Color of edges of all flanges, fittings and valves	Color of pipe fittings, and insulation bands	Color of band	Color of pipe	Color of pipe
Air	gray	black pipe and fittings		dark blue	light green
Air, Compressed			white and black		
Ammonia Gas			white		
Ammonia, Liquid			white		
Brine Return			white and red		
Brine, Supply			white and yellow		
Drip, Gravity discharges from manifold to receiver, from receiver to header, header to boilers and blowdowns and reducer lines		orange pipe and P. Verm. fittings			
Drip, Holly System					cream, buff bands
Electric Lines and Feeders	black and red stripes alternately on flanges and fittings, body of pipe being black				
Drips, Blow off from water columns and all low-pressure drips, roof leaders, overboard discharges from hot-well pumps		lead pipe and black fittings			
Gas, Illuminating	aluminum		white and blue	dark brown	
Gas, Engine Service	black, red flanges				
Oil, Fuel	black				
Oil, Delivery and Discharge, brass or bronze	yellow	tan pipe and black fittings			
Oil, Cylinder, throughout station from barrel tanks to pumps, to overhead tanks, to cylinders		tan pipe and P. Verm. fittings			
Oil, Return, from all bearings and catchalls to filter tanks		tan pipe and light-green fittings			pink
Refrigerating Systems	white and green stripes alternately on flanges and fittings, body of pipe being black				
Steam, High-Pressure	white		black	dark yellow	cream
Steam, Low-Pressure			red		
Steam, Exhaust	buff	buff pipe and fittings, green bands		black	
Steam, Exhaust and Drips					buff
Steam, Live, to engines, turbines, boiler cross-overs, boiler and main headers		black pipe and fittings, brass bands			
Steam, Boiler Blow-off					
Steam, Drip Lines, including drip receivers' discharge to boilers, blowdowns, reducer lines and manifolds		orange pipe and black fittings			black
Steam, Heating System					light gray
All steam lines not included		buff pipe and fittings, black bands			
Vacuum Return			green		
Vacuum Cleaner			green and red		
Water, Fresh, Low-Pressure	blue			gray	
Water, Fresh, High-Pressure (boiler feed)	blue and white				
Water, Salt	green	light green pipe, black fittings			medium blue
Water, Cistern			white and green		
Water, Tank			white and brown		
Water, Well			yellow and black		
Water, Mill			yellow		
Water, Ontario			hrown		
Water, Hemlock			blue		
Water, Cooling			green and black		
Water, Warm, fresh, mains from outlets of jackets and cooling coils to F. W. heaters and hot wells to pumps to feedwater heaters		dark blue-pipe and black fittings			
Water, Feed, from heaters and pumps to boiler drums		Pompeian red pipe and fittings			
Water, Fire Lines, priming lines and all other service using water from fire pumps		permanent vermilion pipe and fittings			
Water, Fire Protection					red
All Fresh-Water Pipe from meters to inlet nozzles for F. W. heaters, water jackets, oil coolers, step-bearing pumps, or to any point where temperature of water changes or mixes with other water		dark blue pipe and P. Verm. fittings			
All Other Water					light blue
Reservoir Return			red and black		

easy one. In fact, one correspondent, Mr. G. E. Sanford, safety engineer of the General Electric Company, remarks that there does not seem to be a sufficient number of satisfactory colors to go around. Two other important considerations in this connection are, first, the tendency of certain colors to fade and in so doing to dangerously approach some other color, thus leading the workman into a false sense of security; and second, the prevalence of color blindness among workers of all classes. On this point Mr. Sanford says:

> From my experience in investigating this matter in plants all over the country, I am thoroughly of the belief that the best plan would be to paint a black band a foot more or less long on each side of each union, valve, or at any place where the pipe line could be taken apart, or at any place where attachments could be made. On that black surface should be stenciled in plain white or aluminum letters, at least one inch high where practicable, the name of the material in the pipe, so that markings on overhead lines could be read from the floor in ordinary well-lighted buildings, provided, of course, that the ceiling was not over the average height.

All those who are in any way interested in the solution of this problem would do well to communicate with C. B. LePage, Secretary of Standards and Technical Committees of the A.S.M.E., stating the phase of the problem which interests them most and volunteering all data at their disposal.

Conference of Secretaries of National Standardizing Bodies

The Secretary of the American Engineering Standards Committee, Dr. P. G. Agnew, has recently returned from London where he attended a conference of the secretaries of the national standardizing bodies. This conference was called by the Secretary of the British Engineering Standards Association, Mr. C. le Maistre, and other countries represented were as follows: Belgium, by G. Gerard; Canada, by R. J. Durley; Holland, by E. Hijmans; Norway, by A. Eriksen; and Switzerland, by M. Zollinger. The object of the conference was the interchange of experience and the furtherance of coöperation between the various national bodies in their work of industrial and engineering standardization. After the conference Dr. Agnew visited France, Switzerland, and Germany for a more detailed study of the standardization work in those countries.

It was found that the same general method of procedure is followed in the different countries: namely, technical decisions concerning any specific piece of work are in the hands of a working committee which is so constituted as to be broadly representative, from both the technical and the managerial points of view, of the particular branch of the national industry concerned. This method, the discussion brought out, is followed whether the work is of the nature of specifications, methods of test, or dimensional standardization.

The conference made the following suggestions which will be submitted by the secretaries to their respective organizations for approval.

The conference advocated that for the present coöperation proceed along such informal lines as the interchange of publications, a reciprocal arrangement for making foreign standards available to the industries of each country through their sale by the offices of the national bodies, the exchange of information as to the status of work in progress, etc.

The conference felt that an attempt to form a general international standardizing body should not be made at the present time but in cases in which formal organization should ater be found necessary, the organization should preferably be by subject or industry, somewhat along the lines of the International Electrotechnical Commission.

Arrangements are being made for close coöperation between the national standardizing bodies and the International Chamber of Commerce. A committee has been organized to develop interest in the subject on the part of industrial and commercial interests, and diffuse information on standardization. It is the policy of the International Chamber of Commerce to further the standardization movement by such means, considering only the more general aspects of the problem, and the policies to be followed, leaving the details of industrial standardization to the national bodies, who will coöperate directly with the national organizations of the International Chamber of Commerce in their respective countries.

Rock Island Excursion

(Continued from page 471)

modern equipment and modern methods were shown ready for use in munitions manufacture. Colonel Jordan led the party through the beautifully-laid-out grounds, the well-arranged and maintained 36 acres of storerooms, and the 2400-kw. hydroelectric station operating at 12 ft. head, all on this wooded island of 900 acres in the Mississippi River.

Luncheon was served in the Arsenal cafeteria, after which the party adjourned to Welfare Hall where the opening session of the Ordnance Division was held, with President Carman in the chair. The technical program was contributed by the officers of the Ordnance Department and was illustrated by moving pictures and lantern slides. In the opening paper, Col. C. L' H. Ruggles made a plea for a policy of munitions preparedness which will enable the country to furnish necessary munitions of satisfactory quality at the time and place required by its armies. He advocated the setting aside of money every year for the maintenance of the large stock of munitions which had been made up for use in the world war.

The remainder of the program was made up of five papers dealing with Progress in Ordnance Development Since the Armistice, namely:

- Artillery, Major G. F. Jenks
- Tanks, Tractors and Trailers, Major L. B. Moody
- Artillery Ammunition, Major W. B. Hardig
- Small-Arms Machine Guns and Their Ammunition, Major L. O. Wright
- Aircraft Armament, Major W. A. Borden.

These papers will be abstracted in a future issue of Mechanical Engineering. Following the technical session, guests were given an exhibition of tractors and tanks in action.

In the evening a dinner was served at the Hotel Blackhawk in Davenport which was attended by the visiting members of the A.S.M.E. and the members of the Tri-Cities engineering societies. Max Sklovsky acted as toastmaster of the banquet and introduced William Butterworth, president of the John Deere Plow Company, who welcomed the guests. President Carman responded for the Society and emphasized the important responsibility of the engineering profession in giving service to the community. Col. A. E. White, president of the American Steel Treaters' Society, made an eloquent address in which he pointed out the necessity for engineering societies to get together for their local activities. He spoke of his experience with the American Steel Treaters' Society, where he found that when engineers in a locality were coöperating the local sections of all of the national societies flourished, and where they did not coöperate the local section of each society was not successful. Calvin W. Rice, Secretary of the Society, Ralph P. Hayes, Chairman of the Davenport Engineering Society, Col. Harry B. Jordan, Commandent at Rock Island Arsenal, and Col. C. L'H. Ruggles of the Ordnance Department, made short addresses.

The following morning a few of the members entered a blind bogie golf tournament held on the Rock Island Arsenal links, Prizes were awarded to J. Edward McDonald, Calvin W. Rice. James F. Lardner, Col. A. E. White, W. H. Kenerson, and H. A. Soverhill. Bert F. Baker, who trailed the field for net score, was awarded a medal on which was significantly inscribed A. A. H. O. G., which interpreted means, Ancient and Honorable Order of Goats. Other of the visitors availed themselves of the opportunity of visiting some of the industrial plants in the locality, leaving for home in the afternoon.

Great credit is due the members of the Tri-Cities Section for the success of an exceedingly interesting two-days' trip. The executive committee of the Tri-Cities Section is: C. R. Adams, Chairman, E. Ransome Jackson, Charles A. Carlson, Clarence W. Fiske, James E. Lardner and H. A. Soverhill.

An Industrial Relations Conference, authorized by Governor William C. Sproul, Pennsylvania, is being arranged by Dr. Clifford B. Connelley, Commissioner of Department of Labor and Industry, Commonwealth of Pennsylvania, to be held at Harrisburg, Pennsylvania, October 24 to 27th.

LIBRARY NOTES AND BOOK REVIEWS

Steam Boiler Engineering

Steam Boiler Engineering (Helios): A Treatise on Steam Boilers and the Design and Operation of Boiler Plants. Twenty-seventh edition. Heine Safety Boiler Co., St. Louis, Mo., 1920. Cloth, 6 by 9 in., 639 pp., illus., diagrams, charts, tables, $1.75.

The first Helios appeared in July 1893. The present volume is announced as the 27th printing or 13th edition. It is really a new book and a very remarkable book. There is little to remind one of the old Helios other than Colonel Meier's preface and the gilded picture of the sun god with his four-horse chariot on the cover. There are 639 octavo pages and while engineers are used to generosity of this sort from boiler manufacturers, one must marvel that any particular manufacturer can give so much. In fact, if it were not for the acknowledged propaganda of the first section and of occasional passages elsewhere, we should have to call this the best textbook on steam boilers that is available. Naturally, therefore, the book represents to a large extent the results of research and publication by others. It is a thorough and adequate presentation of these results.

The steam tables by Goodenough are used throughout the work. The chapter on piping is excellent, containing perhaps more detail than is to be found in any book not devoted exclusively to this subject, and this detail is presented with a good sense of proportion and the relative importance of the topics included. There is a remarkably extensive index covering 21 pages, and it seems to be a good working index.

Fault can be found with the new Helios as with any other book, and no doubt the next one can be made better. One way of making it better will be to drop the time-honored plan of tabulating analyses of coals by states. This is not a useful way. The argument for such a tabulation should be the field, and subordinate to this the geographical location in the field. Fig. 204 showing the coal fields of the United States is rather carelessly drawn. The illustrations are occasionally arranged out of their numerical sequence. The discussion of superheater design on page 81 refers superficially to the mean temperature difference without giving any careful definition of that term. Among miscellaneous fuels there is no mention of garbage or city refuse. The section on the cost of generating steam is entirely inadequate. The paragraph on page 73 with relation to the steam consumption of large turbines as affected by superheat is almost incomprehensible, but upon careful reading it is possible to guess what the writer intended.—W. D. E.

The Conservation of Textiles. By Harvey Gerald Elledge and Alice Lucille Wakefield. Laundryowners National Association, La Salle, Ill., 1921. Cloth, 6 x 8 in., 162 pp. illus., $1.

The results of an investigation of the causes of deterioration in textiles, particularly from laundering, accompanied by advice upon conservation.

The Engineer. By John Hays Hammond. Charles Scribner's Sons. New York, 1921. (Vocational series.) Cloth 194 pp., 4 x 7 in., $1.25.

Mr. Hammond's book is intended as guide and counselor for the youth attracted toward engineering as a profession. Its advantages and disadvantages, the qualities required for success, the best kind of education are clearly set forth, followed by chapters which explain the fields occupied by the major divisions of engineering—mechanical, civil, mining, chemical, marine and military. The book is well fitted to assist in the selection of a career.

Engineering Construction. Part I. In Steel and Timber. By William Henry Warren. Third edition. Longmans, Green and Co., New York, 1921. Cloth, 6 x 9 in., 486 pp., plates, illus., diagrams, $10.

The third edition of this work attempts to include in one volume a summary of the subject: railway and highway bridge design and construction suited for students and engineers. The present edition has been carefully revised, and appendices added on Australian timbers and on recent steel column experiments and formulas.

Die Formstoffe der Eisen—und Stahlgiesserei. By Carl Irresberger. Julius Springer, Berlin, 1921. Paper, 6 x 10 in., 245 pp., illus., 24 Marks.

An extensive treatise on molding sands and their preparation for use in iron and steel founding. The occurrence of suitable sands, clays and loams, their mineralogical formations, properties and the methods of testing are described and the added materials, core binders and facings are discussed. Approximately one-half of the volume is devoted to the questions of drying, grinding and mixing molding sands, the purification of used sand, automatic sand-mixers, etc.

Funfstellige Tafeln der Kreis- und Hyperbelfunktionen. By Keiichi Hayashi. Berlin, Walter de Gruyter & Co., 1921. 182 pp., 9 x 6 in., paper.

The values given in this table are in ten-thousandths from 0 to 0.1, in thousandths from 0.1 to 3, in hundredths from 3 to 6.3 and in tenths from 6.3 to 10. The circular and hyperbolic functions of any number are printed side by side, making it unnecessary to consult two places when using formulas containing both functions.

Lubricating and Allied Oils. By Elliott A. Evans. E. P. Dutton & Co., New York, 1921. (The Directly-Useful Technical Series.) Cloth, 6 x 9 in., 128 pp., illus., $4.

This handbook describes the chemical and physical tests commonly used for determining the properties of a lubricating oil, and discusses those branches of the subject which are of interest. The book is intended to assist chemists in compiling specifications and examining lubricating oils, and to give engineers an insight into the properties and applications of such oils, and the interpretation of specifications.

The Microscope; Its Design, Construction and Applications. Edited by F. S. Spiers. J. B. Lippincott Co., Philadelphia, 1920. Cloth, 7 x 10 in., 260 pp., plates, diagrams, $5.

This volume contains the papers and addresses delivered at a meeting held in January 1920, at the initiative of Sir Robert Hadfield, by the Faraday Society, the Royal Microscopical Society, the Optical Society and the Photomicrographic Society. One purpose of the symposium was to stimulate the study of and research in microscopical science by indicating lines of progress in the design of the instrument, showing recent improvements in the microscope and its technique, and its varied uses as an instrument of research. The papers cover a wide field, including among other subjects the mechanical design, optics and manufacture of microscopes; their applications, especially in metallography, metallurgy, engineering and meteorology; their testing. An historical introduction is given and a bibliography of the chief literature.

National Electrical Safety Code. Issued by U. S. Bureau of Standards. Third edition. Wash., Govt. Printing Office, 1921. (Handbook series, no. 3.) Cloth, 5 x 8 in., 366 pp., $0.40.

About four years ago the Bureau of Standards published the completed text of this Code for examination and trial use, an early revision being contemplated. War conditions interfered with this trial, so that the publication of a new edition has been greatly delayed. The revision is now completed and the revised code is now published in this handbook for more convenient use. The discussion of the rules has been segregated under a separate cover so as to reduce the bulk of the main volume, and will appear as Bureau of Standards Handbook No. 4, now in press.

Oil Fuel. By Edward Butler. Fourth edition. J. B. Lippincott Co., Philadelphia, 1921. Cloth, 5 x 8 in., 310 pp., illus., $3.75.

This book is intended as an exhaustively and systematically classified record of the developments and progress in the application of oil fuel for all steam raising, metallurgical and other purposes, except internal-combustion engines, for which liquid fuel can be used successfully.

The Open Hearth; Its Relation to the Steel Industry, Its Design and Operation. First edition. The Wellman-Seaver-Morgan Co., Cleveland, 1920. Cloth, 9 x 11 in., 378 pp., illus., $7.50. (Sold by U. P. C. Book Co., Inc., N. Y.)

This is a practical book on the design and construction of the open-hearth furnace, and on its use in modern steel making. The methods of working, the gas producers, metal mixers, charging machines and other auxiliaries are described, so that the volume forms a complete, though brief account of open-hearth practice, very fully illustrated by drawings, half-tones and tables of data.

Personnel Relations in Industry. By A. M. Simons. The Ronald Press Co., New York, 1921. Cloth, 6 x 9 in., 341 pp., $3.

The first part of this work gives a survey of the situation in American industry and analyzes the elements of the employment problem. The specific stages through which the questions at issue have passed are then reviewed, after which the author summarizes the best recent thought on the broad question of democracy in industry. Throughout the author has tried to call attention to the scientific laws that have merged from recent study of the subject, and to determine the reactions of human nature to the conditions presented in the various industrial problems.

Die Praktische Nutzanwendung der Prufung des Eisens Durch Aetzverfahren und mit Hilfe des Mikroskopes. By E. Preuss. Second edition. Julius Springer, Berlin, 1921. Paper, 6 x 9 in., 124 pp., illus., 14 Marks.

The present book is intended as a guide in the practical use of microscopic methods of testing the quality of iron, of sufficient scope to meet the ordinary needs of steel-works metallurgists and testing engineers. The methods of etching and polishing are given, and the useful tests for determining structure, controlling heating, tempering, etc. are described.

Relativity, The Electron Theory and Gravitation. By E. Cunningham. Second edition. Longmans, Green and Co., New York, 1921. Cloth, 6 x 9 in., 148 pp., $3.50.

The primary purpose of this monograph was to set out as clearly and simply as possible the relation of the principle of relativity to the electron theory, in a way useful to the general reader and especially to the experimental physicist. In the present edition a second section has been added, which presents the general principle in its present form.

Sheet-Metal Drafting. By Ellsworth M. Longfield. First edition. McGraw-Hill Book Company, Inc., New York, 1921. (Industrial education series.) Cloth, 6 x 9 in., 236 pp., illus., $2.25.

This text was prepared especially for correspondence-study instruction in the Extension Division of the University of Wisconsin. It is also adapted as a textbook for vocational schools. The underlying principles of sheet-metal pattern drafting are presented, the principles being arranged in sequence with due regard to the factors governing the student's progress through a course of instruction.

Small Motors, Transformers, Electromagnets. By H. M. Stoller, F. E. Austin, E. W. Seeger. American Technical Society, Chicago, 1920. Cloth, 6 x 8 in., 320 pp., illus., $3.

The first section of this book discusses small motors, automobile starting motors and charging generators and farm lighting outfits. Typical designs are given for d.c. motors of all standard voltages, ranging from 0.01 hp. to 0.5 hp. in size, and for a.c. induction motors from 0.125 to 0.5 hp. in size.

The second section, on small low-tension and high-tension transformers, treats of those which will transform from 110 to 220 volts and down to the lower voltages. The concluding section includes typical designs of electromagnets for direct and alternating current work and induction coils. Flat-plunger, cone-plunger, horseshoe and clapper electromagnets and portative magnets are considered.

Statique Graphique et Resistance des Materiaux. By Louis Roy. Gauthier-Villars et Cie, Paris, 1921. (Cours de mécanique appliquée, 2.) Paper, 6 x 10 in., 213 pp., 30 francs.

This volume on graphic statics and resistance of materials is the second of a series of volumes by professors in the Institute of Electrotechnics and Applied Mechanics of the University of Toulouse, presenting the course in applied mechanics given to students at the Institute. The author has attempted to present the subject as rigorously as its nature permits and to cover completely those applications of actual interest to the engineer. By omission of other questions, the text has been compressed to moderate size.

Telephotography. By Cyril F. Lan-Davis. Second edition, by L. B. Booth. E. P. Dutton & Co., New York, 1921. Cloth, 5 x 7 in., 116 pp., Illus., plates, $2.00.

The book expounds the theory of telephotography, describes the commercial lenses and gives the practical methods in careful detail. The various applications are fully illustrated.

The Third Power Kink Book. Compiled by the editorial staff of Power. First edition. McGraw-Hill Book Co., Inc., New York, 1921. Cloth 6 x 9 in., 264 pp., illus., $1.50

A collection of some three hundred unconventional but practical ways of meeting power-plant emergencies, of the kind that arise in operation and in repair work.

Thomas' Register of American Manufacturers. Twelfth edition. Thomas Publishing Co., New York. 19 x 10 Cloth, 10 x 12 in., $15.

The twelfth edition of this popular directory of manufacturers and dealers presents no novelties in arrangement or contents. According to its publishers, however, over 200,000 changes have been made in order to keep the lists complete and accurate. The Register is a directory of first hands in all lines, classified under several thousand subjects and fully indexed, so that the makers of any article may readily be found. Companies are also listed alphabetically, with data upon branch offices, capital, location, etc. A list of trade names is given, showing the owners of the various trade marks. In addition to these main divisions, the Register also contains lists of representative banks, commercial organizations, exporters and importers, and trade papers, making it a most complete work of reference for buyers and sellers.

La Theorie de la Relativite Restreinte et Generalisee. By A. Einstein. Gauthier-Villars et Cie, Paris, 1921. Paper, 5 x 7 in., 120 pp., 7 francs.

This French edition of Dr. Einstein's popular presentation of the theory of relativity is based on the second German edition. A lengthy preface by Emile Borel discusses the value of the theory and the limits of its practical use.

United States Steel—A Corporation with a Soul. By Arundel Cotter. Doubleday, Page and Co., Garden City, N. Y., 1921. Cloth, 6 x 8 in., 312 pp., portraits, plates, $3.

This is an enlarged and modernized edition of The Authentic History of the United States Steel Corporation. It gives a well written account of the reasons for its organization, its history, activities, aims and policies, relations with its employees, together with some account of important officials, past and present.

Die Warmeverluste Durch Ebene Wande unter Besonderer Berücksichtigung des Bauwesens. By Karl Hencky. R. Oldenbourg, München und Berlin, 1921. Paper, 7 x 10 in., 124 pp., illus., tables, 26 marks.

This work is based on extensive experiments on the heat conductivity of walls of the usual types and of the customary building materials, carried out at the Munich Technical High School. From the results of these and general laws of the conduction of heat, the author has formulated equations to be used in designing heating installations. The book is intended for architects and for engineers engaged in the design of heating plants, as a practical aid in calculating the size of installations.

Wirtschaftliche Verwertung der Brennstoffe. By G. de Grahl. Second revised edition. R. Oldenbourg, München and Berlin, 1921. Paper, 8 x 11 in., 485 pp., plates, illus., charts, diagrams, 110 marks.

This work on the economical utilization of fuels first appeared in 1915, when the economic isolation of Germany began to be effective. The present edition has been entirely rewritten in the light of the fuel situation after the war, and is an exhaustive treatise on the utilization of the available fuel supply under present conditions. After a description of the solid, gaseous and liquid fuels, in which their efficiencies are compared, the author discusses the processes for converting and enriching them. Gas production, by-products, nitrogen utilization are treated in detail. The subject of combustion is then taken up, and an extended critical discussion of methods of firing, especially for steam production, is included. Another chapter discusses heating for municipalities, waste heat utilization, etc. The concluding chapter treats of the economics of energy in general.

Wireless Telegraphy with Special Reference to the Quenched-Spark System. By Bernard Leggett. E. P. Dutton & Co., New York, 1921. (The Directly-Useful Technical Series.) Cloth, 6 x 9 in., 485 pp., illus., plates, $12.

This volume is intended to provide a treatise in English on radiotelegraphy in which particular attention is given to the quenched-spark system. Bibliographies are appended to many chapters.

THE ENGINEERING INDEX

(Registered U. S. Patent Office.)

THE ENGINEERING INDEX presents each month, in conveniently classified form, items descriptive of the articles appearing in the current issues of the world's engineering and scientific press of particular interest to mechanical engineers. At the end of the year the monthly installments are combined along with items dealing with civil, electrical, mining and other branches of engineering, and published in book form, this annual volume having regularly appeared since 1906. In the preparation of the Index by the engineering staff of The American Society of Mechanical Engineers some 1200 technical publications received by the Engineering Societies Library (New York) are regularly reviewed, thus bringing the great resources of that library to the entire engineering profession.

Photostatic copies (white printing on a black background) of any of the articles listed in the Index may be obtained at a price of 25 cents per page, plus postage. A separate print is required for each page of the larger periodicals, but wherever possible two small or medium-sized pages will be photographed together on the same print. The bill will be mailed with the print. When ordering photostats identify the article by quoting from the Index item: (1) Title of article; (2) Name of periodical in which it appeared; (3) Volume, number, and date of publication of periodical; (4) Page numbers. Orders should be sent to the Engineering Societies Library, 29 West 39th Street, New York.

ACCIDENTS

Dust Explosions. An Explosion of Hard Rubber Dust, David J. Price and Hylton R. Brown. Chem. & Metallurgical Eng., vol. 24, no. 17, April 27, 1921, pp. 737–740, 5 figs. Results of investigation of recent explosion in reduction of hard-rubber scrap department of large industrial plant. Recommendations for prevention and precautions to be taken in hard-rubber grinding.

AERODROMES

France. French State Aerodromes for Civil Use. Aviation, vol. 10, no. 20, May 16, 1921, pp. 638–639, 6 figs. Types of aerodrome built by French government.

AERODYNAMICS

Wind-Tunnel Experiments. Extract from a Report of the Resistance of Spheres of Small Diameter in an Airstream of High Velocity, Capt. Toussaint and Lieut. Hayer. Aerial Age, vol. 13, no. 9, May 9, 1921, pp. 199–200, 3 figs. Interpretation of results found in wind-tunnel experiments at Aerotechnical Inst. of Saint-Cyr, France, and comparison with results found by other experimenters.

AERONAUTICAL INSTRUMENTS

Accelerometer. Accelerometer Design, F. H. Norton and Edward P. Warner. Nat. Advisory Committee for Aeronautics, no. 100, 1921, 16 pp. 14 figs. Experimental work carried out by technical staff of Nat. Advisory Committee for Aeronautics for the purpose of recording errors due to accelerations acting in other than required direction and also errors due to angular accelerations.

Driftograph. The Driftograph. Sci. Am. Monthly, vol. 3, no. 5, May 1921, pp. 453–454, 1 fig. Instrument for determining drift of aircraft. Translated from Génie Civil.

AERONAUTICS

National Advisory Committee. Special Report of the National Advisory Committee for Aeronautics. Aviation, vol. 10, no. 18, May 2, 1921, pp. 553–558. Federal regulation of air navigation; air routes to cover whole U. S.; coöperation among government departments. Submitted to President of U. S., April 9, 1921.

Special Report of the National Advisory Committee for Aeronautics. Aerial Age, vol. 13, no. 9, May 9, 1921, pp. 200–202. (Concluded.)

Reactive Propulsion in Air. Possibility of Reactive Propulsion in Air, B. T. Koleroff. Aviation, vol. 10, no. 20, May 16, 1921, pp. 624–625. Underlying principles to which device operating by reactive propulsion must conform.

Research Laboratory. The Aeronautic Research Laboratory at the Institute of St. Cyr, John Jay Ide. Automotive Industries, vol. 44, no. 16, April 21, 1921, pp. 853–855, 5 figs. Facilities for aerodynamic investigations include two wind tunnels of different size, whirling arm, and two electrically operated trucks running on rails, all of which are equipped for determining characteristics of airfoils. One truck is designed for testing propellers.

Tests. Review on Experimental Aerotechnics (Revue d'aérotechnique expérimentale), L. Toussaint. Revue générale des Sciences, vol. 32, no. 7, April 15, 1921, pp. 203–213, 2 figs. Aerodynamic principles experimentally established at principal aeronautical laboratories of the world.

AEROPLANE ENGINES

Cooling Systems. Cooling System Flight Test of Loening M-8. U. S. War Dept., Air Service Information Circular, vol. 3, no. 206, April 30, 1921, 8 pp. 5 figs. Object was to determine effectiveness of cooling system of Loening monoplane, model M-8.

Design. The Ultimate Airplane Engine, Jesse G. Vincent. Aviation, vol. 10, no. 18, May 2, 1921, pp. 567–569. Possibilities of utilizing steam engine, steam turbine or electrical propulsion for aeroplane propulsion.

Exhaust Silencer. The Martin Exhaust Silencer. Aeronautics, vol. 20, no. 392, April 21, 1921, pp. 278, 2 figs. Silencer built of light-gage iron sheet, riveted and welded together.

Haacke. The Haacke 30 H. P. Aero Engine. Flight. vol. 13, no. 14, April 7, 1921, pp. 239–240, 5 figs. Two-cylinder opposed air-cooled model developing 30 hp.

Liberty. Performance of a Liberty 12 Airplane Engine, S. W. Sparrow and H. S. White. Nat. Advisory Committee for Aeronautics, no. 102, 1921, 20 pp. 16 figs. Tests conducted in altitude chamber of dynamometer laboratory of Bur. of Standards. Engine was tested under full power run at ground altitude at speeds from 1200 to 2000 r.p.m. and at speeds at 1600 and 1700 r.p.m. at full throttle from ground altitude to 25,000 ft. in steps of 5000 ft. Propeller-load runs and friction-horsepower runs were also examined.

Test of a Standard Liberty Cylinder Mounted on a Universal Engine Crank Case. U. S. War Dept., Air Service Information Circular, vol. 2, no. 199, April 25, 1921, 10 pp. 6 figs. Measurement of power friction losses, temperatures and heat-transfer characteristics of standard Liberty cylinder when mounted on universal engine.

Napier "Cub." The Napier "Cub" Engine. Automobile Engr., vol. 11, no. 149, April 1921, pp. 146–147, 2 figs. Four sets of four cylinders. Included angle between uppermost blocks of cylinders is 52 1/2 deg. and between bottom blocks 127 1/2 deg. Engine develops 1000 hp.

Operation with Automobile Gasoline. Operating Liberty "12" and Wright-Hispano 300-Hp. Engines on Automobile Gasoline. U. S. War Dept., Air Service Information Circular, vol. 3, no. 227, May 10, 1921, 4 pp. It is recommended that use of such fuel in engines should be avoided whenever possible and in cases of necessity engines should be run throttled while on or near ground.

Performance. Investigation of the Effect of Air Conditions Upon the Power of Aviation Engines, Harold S. White. Armour Engr., vol. 12, no. 3, Mar. 1921, pp. 135–144, 3 figs. Investigations of theory establishing that power is proportional to density or inversely proportional to absolute temperature. Development of new theory.

Some Factors of Airplane Engine Performance, Victor R. Gage. Nat. Advisory Committee for Aeronautics, Report No. 108, 1921, 29 pp., 28 figs. Tests on Liberty 12 and three models of Hispano-Suiza made in altitude chamber where conditions simulated altitudes up to about 30,000 ft. at engine speeds ranging from 1,200 to 2200 r.p.m.

Power at High Altitudes. Influence of Flight at High Altitudes on Power of Aeroplane Engines (Influence du vol à haute altitude sur la puissance du moteur d'un aéroplane), M. Collette. Arts et Métiers, vol. 74, no. 2, Feb. 1921, pp. 49–51, 4 figs. Graph for determining altimetric reduction of power of aeroplane engines from temperature and barometric pressure.

AEROPLANE PROPELLERS

Design. Aeronautic Propeller Design, F. W. Caldwell. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 467–480, 26 figs. Propeller-design theories and aerodynamic principles are discussed mathematically, as well as elements governing best propeller diameter for obtaining highest thrust. Consideration is given in detail to adjustable-pitch and reversible propellers as well as to those made up of laminations or sheets of paper or fabric impregnated with bakelite as binder.

Variable-Pitch. The Parker Variable Pitch Airscrew. Flight, vol. 13, no. 15, April 14, 1921, pp. 257, 2 figs. Pitch changes automatically as density of air decreases with altitude, also when engine misfires or slows down.

AEROPLANES

Aerofoils. Aerodynamic Characteristics of Aerofoils. Nat. Advisory Committee for Aeronautics, report no. 93, 1921, 83 pp, 218 figs. Collection of data on aerofoils from published report of leading aerodynamic laboratories of U. S. and Europe. Charts and tables for use of designing engineers and for general reference.

The German Lachmann Slotted Aerofoil. Flight, vol. 13, no. 14, April 7, 1921, pp. 242, 2 figs. Translated from Flugsport.

The Resistance of Aerofoils, W. F. Gerhardt Aerial Age, vol. 13, no. 8, May 2, 1921, pp. 175–178, 13 figs. Methods of plotting aerofoil characteristics, (Concluded.)

All-Metal. German All-Metal Commercial Machines, Alfred Gradenwitz. Aeronautics, vol. 20, no. 394, May 5, 1921, pp. 314–316, 5 figs. Dornier types.

The New German All-Metal Aeroplanes (Les nouveaux avions métalliques allemands), E. H. Lémonon. Aerophile, vol. 29, nos. 5–6, Mar. 1–15, 1921, pp. 71–78, 16 figs. Junkers types.

Design. Influence of Span and Load Per Square Meter on the Air Forces of the Supporting Surface, A. Betz. Aerial Age, vol. 13, no. 10, May 16, 1921, pp. 224–225, 4 figs. Formulas. Translated from Technische Berichte.

Load Factors. Aeronautics, vol. 20, no. 391, April 14, 1921, pp. 254–255. Scale of load factors and factors of safety prepared by British Advisory Committee for Aeronautics.

Flight Endurance. Notes on Airplane Flight Endurance. U. S. War Dept., Air Service Information Circular, vol. 3, no. 210, May 1, 1921, 6 pp., 1 fig. Chart for determining minimum horsepower required or maximum horsepower available at any altitude that aeroplane can reach.

Flight Without Propellers. New Air Transport Theory, Harry Harper. Motor Transport, vol.

32, no. 843, April 25, 1921, pp. 442–443. Pulsating wing invented by Prof. Raimund Nimführ. Wing is hollow with air bags inside, underneath section taking form of flexible membrane, which can be set beating or pulsating by action of pneumatic pumps which alternately fill or empty air bags. Aeroplane without propellers, impelled by pulsating wing, is to be manufactured by American syndicate.

Hispano-Suiza. Performance of a 300-Horsepower Hispano-Suiza Airplane Engine, S. W. Sparrow and H. S. White. Nat. Advisory Committee for Aeronautics report no. 103, 1921, 22 pp. 16 figs. Test showed inadequacy of carburetor altitude control of air-fuel ratio for heights above 20,000 ft.

Saulnier. The R. Saulnier Triple-Motored Monoplane (Le monoplan trimoteur R. Saulnier). Aérophile, vol. 29, nos. 5–6, Mar. 1–15, 1921, pp. 67–69, 6 figs. Characteristics: Engines, 3 Lorraine-Dietrich of 370 hp. each; weight loaded, 7000 kg.; useful weight, 2700 kg.

Strutless Supporting Planes. Aeroplanes with Strutless Supporting Planes (Flugzeuge mit verspannungslosen Tragflächen), E. Meyer. Schweizerische Bauzeitung, vol. 77, no. 15, Apr 9, 1921, pp. 166–168, 7 figs. Points out aerodynamic superiority of aeroplanes with freely supported strutless planes based on the Junkers principle, and refers to various recent commercial and sport types constructed with view to reducing the resistance-producing parts to a minimum.

Struts. The Design of Long Struts Exposed to the Air, John Case. Aeronautics, vol. 20, nos. 391 and 392, April 14 and 21, 1921, pp. 257–258, 4 figs., and 272–274, 5 figs. Apr. 14: formulas for computing dimensions of different types. Apr. 21: Method of designing taper struts having parallel hole.

[See also HELICOPTERS; PARACHUTES, SEAPLANES.]

AIR

Moisture Content. The Moisture Content of Atmospheric Air (Der Wasserdampfgehalt der Luft), Karl Reyscher. Gesundheits-Ingenieur, vol. 44, no. 15, Apr. 9, 1921, pp. 168–170, 1 fig. Values for pressures in saturated steam, weight of steam and of pure air, etc. are given in tabular form from which curves are developed.

AIR MACHINERY

Classification. Classification and Nomenclature of Air Machinery (Gliederung und Bezeichnung der Luftfördermaschinen), M. Berlowitz. Gesundheits-Ingenieur, vol. 44, no. 13, Mar. 26, 1921, pp. 141–143, 1 fig. Suggestions for a standardization of terms for pumps and compressors.

AIRCRAFT CONSTRUCTION MATERIALS

Brazing. Report on Investigation of Dip Brazing with 80–20 Brass. U. S. War Dept., Air Service Information Circular, vol. 3, no. 203, April 30, 1921, 8 pp. 8 figs. Objects were to determine best flux to use in brazing and effects of heat treatment on brazed joints, and to develop satisfactory method of brazing with 80 per cent copper and 20 per cent zinc mixture.

Plywood. Plywood in Airplane Construction, Armin Elmendorf. Aviation, vol. 10, no. 21, May 23, 1921, pp. 660–663, 7 figs. Uses in construction of semi-monocoque fuselage. Table of weights of veneer. (Concluded.)

AIRSHIPS

German. Development and Present Status of German Airships. Automotive Industries, vol. 44, no. 20, May 19, 1921, pp. 1057–1065, 1 fig. Tables giving characteristics of German airships built up to May 1921. Survey of technical successes and failures of various types. Comparison of performance of R-34 with that of German L-59 which made trip to East Africa.

Hangars. See HANGARS.

Mooring Gear. Airship Mooring Gear. Engineering, vol. 111, no. 2884, April 8, 1921, pp. 423–424 and 426, 4 figs. Experimental mooring mast designed and installed by British Air Ministry.

An American System of Airship Mooring. Aeronautics, vol. 20, no. 391, April 14, 1921, p. 256, 4 figs. Airship is anchored to 5 trolleys running under circular slots in platform.

Mooring Masts for Airships. Aviation, vol. 10, no. 21, May 23, 1921, p. 665, 1 fig. Webbed-steel structure 115 ft. in height, with revolving circular platform housed-in at top and above platform mooring. Apparatus of cylindrical form swung on gimbals, which permits ship when moored to sway with wind. Mast erected at Pulham, England.

R-36. The Passenger-Carrying Airship R-36. Engineering, vol. 121, no. 2885, April 15, 1921, pp. 454–456 and 458, 28 figs. partly on supp. plate. Characteristics: Overall length, 672 ft. 2 in.; maximum diameter of hull, 78 ft. 9 in.; height from bumping bags to top of hull structure, 91 ft. 7 in.; gas capacity, 2,196,000 cu. ft.; carried in 19 bags; gross lift, 64.5 tons.

Rigid. Circumferential Wiring of Rigids, E. H. Lewitt. Aeronautics, vol. 20, no. 395, May 12, 1921, pp. 336–338, 8 figs. Study of stresses.

[See also AERODROMES.]

ALCOHOL

Coke-Oven Gas. The Manufacture of Alcohol from Coke-Oven Gas, C. F. Tidman. Jl. Soc. Chem. Industry, vol. 40, no. 8, April 30, 1921, pp. 86T–89T, 2 figs. Record of work carried out at Skinningrove Iron Works, England.

Industrial. Industrial Alcohol (L'alcool industriel), Charles Blanchet. Revue de l'Ingenieur et Index technique, vol. 28, no. 4, April 1921, pp. 179–185. Requirements for manufacture of industrial alcohol. Possibility of utilizing alcohol as automobile fuel. (To be continued.)

Industrial Alcohol and Prohibition Enforcement, Martin H. Ittner. Chem. Age (N. Y.), vol. 29, no. 6, June 1921, pp. 211–212. Resolutions adopted by Am. Chem. Soc. urge that all legislation for enforcement of prohibition "be so clearly drawn as not to restrict the activities of legitimate industries which must have industrial alcohol."

ALLOY STEELS

Chromium-Tungsten. Constitution of Chromium: Tungsten Steels. Chem. & Metallurgical Eng., vol. 24, no. 18, May 4, 1921, pp. 791–793, 8 figs. Recent Japanese work throwing light upon complex reactions giving self-hardening and red-hardness properties to modern high-speed steels. From Sci. Reports of Tohoku University.

ALLOYS

See ALUMINUM ALLOYS; ZINC ALLOYS; BEARING METALS; BRONZES; COPPER ALLOYS; GUN METAL; PHOSPHOR BRONZE.

ALUMINUM

Casting Losses. Losses in Aluminum and Aluminum-Alloy Melting, Robert J. Anderson, U. S. Dept. of Interior, Bur. of Mines, Reports of Investigations, no. 2239, April 1921, 6 pp. Factors in operation of furnaces that affect casting losses.

ALUMINUM ALLOYS

Melting Practice. Iron-Pot Melting Practice for Aluminum Alloys, Robert J. Anderson. Metal Industry (N. Y.), vol. 19, no. 5, May 1921, pp. 189–190. Design of iron-pot furnaces.

AMMONIA CONDENSERS

Selection. The Proper Selection of Ammonia Condensers, W. H. Motz. Power, vol. 53, no. 17, April 26, 1921, pp. 659–662, 4 figs. Economic considerations.

ANEMOMETERS

Comparison of. Comparison of Anemometers (Sur la comparabilité des anémomètres), M. C.-E. Brazier. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 14, April 4, 1921, pp. 843–845. Comparison of various types in currents of air inclined at an angle.

APPRENTICES, TRAINING OF

Methods. Programs of Apprenticeship and Special Training in Representative Corporations—XII, J. V. L. Morris. Am. Mach., vol. 54, no. 18, May 5, 1921, pp. 778–779, 4 figs. Method of training apprentices at plant of Packard Motor Car Co., Detroit, Mich.

National Instructional Factories. Industrial Training. Times Eng. Supp., no. 558, April 1921, p. 132. Discusses organization of national instructional factories for training and education industrial apprentices.

Railways. Paris-Orleans Apprentice Work Organized. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 313–316, 4 figs. Description of development of courses for apprentices of Paris-Orleans during war. Translated from Revue Générale des Chemins de Fer.

AUTOGENOUS WELDING

German Code, Revised. Revision of Acetylene Code (Abänderung des Entwurfes der Acetylenverordnung). Autogene Metallbearbeitung, vol. 14, no. 7, Apr. 1, 1921, pp. 98–107. Proposal is result of conference of members of German Acetylene Assn. for Autogenous Metalworking, Federation of German Autogene Industry, and government officials, and represents a complete revision of existing code of 1914 and of proposal of Bavarian Government.

AUTOMOBILE ENGINES

Carburetors. See CARBURETORS.

Heavier Oil Fuels, Use of. Experiences with the Use of Heavier Oil Fuels in Automobile Engines (Erfahrungen und Erwägungen über die Verwendung schwererer Brennstoffe im Automobilmotor), J. Plünzke. Motorwagen, vol. 24, nos. 8 and 9, Mar. 20 and 31, 1921, pp. 150–158 and 169–178, 41 figs. Discussion, based on experience, of means of improving carburetor type of engine for rational use of medium-weight in place of light oils.

Highway. Non-Detachable Head Used in New Stock Engine, J. Edward Schipper. Automotive Industries, vol. 44, no. 16, April 21, 1921, pp. 844–846, 4 figs. Engine manufactured by Highway Engine Co. has four cylinders, 3¾ by 5 in., and develops maximum of 48 hp. Both halves of crankcase and water-jacket cover are aluminum castings. Valve caps are screwed into cylinder head. Full pressure lubrication employed.

Valves, Grinding-in. Electric Machines for Grinding-in Valves. (Elektrische Ventileinschleifmaschine), H. Seiler. Allgemeine Automobil-Zeitung, vol. 22, no. 5, Jan. 29, 1921, p. 29, 2 figs. Describes German patented machine which can also be used as a drilling machine and consists mainly of a small electric motor of 1/15 to 1/20 hp. with the necessary gear.

AUTOMOBILE FUELS

Characteristics. The Character of Various Fuels for Internal Combustion Engines—III, H. T. Tizard and D. R. Pye. Automobile Engr., vol. 11, no. 149, April 1921, pp. 134–137, 2 figs. Influence of specific heat and dissociation of working fluid. Calculation of final temperature and work done during expansion.

Research. Résumé of Bureau of Standards Fuel Study, H. C. Dickinson. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 482–486, 6 figs. Two types of experiments were undertaken; steady runs to determine rate of fuel consumption under load conditions, at about one-fifth maximum mean effective pressure and speed of 1200 r.p.m., and series of repeated accelerations from 10 to about 30 m.p.h. In each case fuel consumption was recorded.

The Influence of Various Fuels on the Performane of Internal Combustion Engines—III and IV, H. R. Ricardo. Automobile Engr., vol. 11, nos. 149 and 150, April and May 1921, pp. 130–133, 5 figs., and 169–175, 14 figs. April: Experimental study of relationship between detonation point and spontaneous ignition temperature. May: Experimental investigation of power output from different fuels, with constant and with adjusted compression ratios.

The Influence of Various Fuels on Engine Performance—II and III, H. R. Ricardo. Automotive Industries, vol. 44, nos. 16 and 19, April 21 and May 12, 1921, pp. 856–862, 6 figs., and 1003–1007, 12 figs. Research on detonation and effect thereon of combustion chamber design, turbulence, speed of rotation, temperature and pressure are discussed at length, and measurement of value of fuel in terms of its tendency to detonate are tabulated and plotted in their relation to other important factors.

[See also ALCOHOL.]

AUTOMOBILES

Bodies. Automobile Body Construction, P. E. Stone. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 404–409. Notes on strength and desirability of materials suitable for construction of enclosed type of body.

Some Examples of Modern Passenger Car Bodies Designed in Germany, Benno R. Dierfeld. Automotive Industries, vol. 44, no. 17, April 28, 1921, pp. 897–899, 11 figs. Designs embodying V-type radiator and windshield, concealed top and divided rear seat.

Cleaning Parts for Repair Work. Modern Boiling Apparatus for Automobile Factories and Repair Workshops (Neuzeitliche Abkochanlagen für Automobilfabriken und Ausbesserungswerkstätten), H. Toepel. Automobil-Rundschau, vol. 20, no. 5–6, Mar. 1921, pp. 53–55, 3 figs. Details of vats patented by Hannover Machine Constr. Corp. (Hanomag) for cleaning of automobile parts preliminary to repair work by boiling in lye.

Fuel Cocks. The Pallas Fuel Cock as Protection Against Theft of Automobiles (Der verschliessbare Pallas-Brennstoffhahn), E. Jaenichen. Allegemeine Automobil-Zeitung, vol. 22, no. 7, Feb. 12, 1921, p. 27, 2 figs. Describes fuel cock, connecting in fuel pipe to carburetor, which can be closed and opened with a key, construction being such that key fits only the one cock for which it is intended.

Manufacture. A Modern Automobile Factory. Eng. Production, vol. 2, no. 31, May 5, 1921, pp. 575–583, 26 figs. Production methods at works of Arrol-Johnston, Dumfries, Scotland.

Special Machines and Fixtures in the Franklin Plant, Franklin D. Jones. Mach. (N.Y.) vol. 27, no. 9, May 1921, pp. 823–830, 19 figs. Mechanical equipment designed either to increase production, perform special operations, or maintain established standards of accuracy.

Wrenches. Manufacture of Socket Wrenches, P. Baldus. Machy. (N.Y.), vol. 27, no. 9, May 1921, pp. 868–869, 4 figs. Practices of various automobile manufacturers.

AVIATION

Aerial Lighthouses. The Aerial Lighthouse. Flight vol. 13, no. 16, April 21, 1921, pp. 280–283, 7 figs. Suggested design.

Canadian Air Board. Report of the Canadian Air Board for the Year 1920. Flying, vol. 10, no. 4, May 1921, pp. 139–143. Board was created (1) to regulate civil aviation, (2) to conduct civil government operations, and (3) to develop air defense of Canada, including organization and administration of Canadian Air Force.

Commercial. European Air Lines. Aeronautics, vol. 20, no. 395, May 12, 1921, pp. 332–334, 6 figs. Air routes which are now in operation in Europe, with fare tariffs and timetables.

Landings, Marking. Air Service Adopts Location Marker. Aviation, vol. 10, no. 17, April 25, 1921, p. 527, 2 figs. Specifications of locations marker adopted by U. S. Air Service.

Mail Service. Three Years of Air Mail Service. Aviation, vol. 10, no. 18, May 2, 1921, pp. 559–564, 5 figs. Comparison of performance of U. S. Air Mail Service and of British and Canadian civil flying.

National Advisory Committee for Aeronautics. Special Report of the National Advisory Committee for Aeronautics. Aerial Age, vol. 13, no. 8, May 2, 1921, pp. 178–180. Federal regulation of air navigation. Air routes to cover whole U. S. Coöperation among government departments.

Soaring Flight. The Soaring Flight of Birds and the Possibility of a Mechanical Imitation. (Der Segelflug der Vögel und die Möglichkeit einer Künstlichen Nachahmung), Carl Steiger. Schweizerische Bauzeitung, vol. 77, no. 15, Apr. 9, 1921, pp. 168–169. Critical discussion of Lilienthal's paper with above title reported in same journal (nos. 11 and 12, Mar., 1921).

Speed of Flights. The Question of Speed (Le problème de la vitesse), J. Philippe. Aéronautique, vol. 3, no. 22, Mar. 1921, pp. 136–137. Theoretical conditions necessary for obtaining high horizontal speed.

B

BEARING METALS

Anti-Friction. Anti-Friction Bearing Metals, P. W. Priestley. Metal Industry, (Lond.), vol. 18, no. 17, April 29, 1921, pp. 323–324. Typical compositions of anti-friction methods employed in construction of aeroplanes and automobile engines.

Research. Results of Investigation Covering Bearing Metals. Belting, vol. 18, no. 4, April 1921, pp. 63–64. Report of committee on mechanical standards, Canadian Pulp & Paper Assn., at recent Montreal convention.

BEARINGS

Examination. A Microphone "Stethoscope" for Bearings. Engineering, vol. 111, no. 2888, May 6, 1921, pp. 546, 3 figs. Apparatus for examining condition of bearings and gears by electricity.

BEARINGS, BALL

Manufacture. The Ball Bearing—I, Henry L. Heathcote. Machy. (Lond.), vol. 18, no. 448, April 28, 1921, pp. 114–119, 3 figs. Notes on manufacture and testing.

The Ball Bearing: In the Making, Under Test and on Service, Henry L. Heathcote. Automobile Eng., vol. 11, no. 150, May 1921, pp. 180–187, 6 figs. Mathematical study of action of ball bearings, together with notes on their manufacture and suggested method of testing them.

The Manufacture of Ball Bearings. Engineering, vol. 111, nos. 2884 and 2885, April 8 and 15, 1921, pp. 415–418, 20 figs. partly on 3 supp. plates, and 445–449, 18 figs. Procedure at works of Ransome & Marles Bearing Co., England.

BEARINGS, ROLLER

Manufacture. Maintaining Continuity Throughout Roller Bearing Manufacture, J. Edward Schipper. Automotive Industries, vol. 44, no. 17, April 28, 1921, pp. 912–917, 22 figs. Methods used at plant of Timken Roller Bearing Co., Canton, Ohio.

N.K.A. A New Disk Type Bearing. Automotive Industries, vol. 44, no. 19, May 12, 1921, p. 996, 2 figs. N.K.A. Swedish disk. Disks are not cylindrical but are central sections of ellipsoid of revolution. Bearing comprises two race rings provided with grooves in which disks run.

BLAST-FURNACE GAS

Cleaning. Notes on the Cleaning of Blast-Furnace Gas, S. H. Fowles. Engineering, vol. 111, no. 2889, May 13, 1921, pp. 600–602, 7 figs. Methods of operating Halberg-Beth dry gas cleaning plant. (Abstract). Paper read before Iron & Steel Inst.

BLAST FURNACES

Charging. Husson Incline System of Charging Materials Into Blast Furnaces (Monte-charge incliné système "Husson" pour haut-fourneau), M. H. Barral. Revue de Métallurgie, vol. 18, no. 2, Feb. 1921, pp. 92–95, 9 figs. Modification of Staehler system.

Design. Stack Changes Effect Economy, H. R. Stuyvesant. Iron Trade Rev., vol. 68, no. 19, May 12, 1921, pp. 1312–1313 and 1316, 3 figs. Improvements in cooling equipment, lines and hearth of Alabama blast furnace, together with introduction of casting machine and new trestle.

BLOWING ENGINES

Gas-Driven. 13 H.P. Gas-Driven Blowing Engine. Engr., vol. 131, no. 3409, April 29, 1921, pp. 451–454, 4 figs. partly on supp. plate. Engines manufactured at Galloway Works, Manchester, England.

BLUEPRINTING

Machines. Recent Progress in Blue Printing. Sci. Am., vol. 124, no. 20, May 14, 1921, p. 389, 1 fig. Machines that print, wash and dry blueprints in continuous operation.

BOILER FEEDWATER

Analyses. The Interpretation of Boiler-Water Analyses, J. R. McDermet. Mech. Eng., vol. 43, no. 5, May 1921, pp. 319–320 and 342. Limitations and applications of technical or mineral analysis. Use of partial sanitary analysis as forecasting possible trouble due to pollution. Significance of analysis for dissolved gases in relation to conditions under which it is used.

BOILER FIRING

Pulverized Coal. Economical Firing of Steel Plant Boilers, Charles Longenecker. Blast Furnace & Steel Plant, vol. 9, no. 5, May 1921, pp. 308–310 and 336. Comparison of hand-fired, stoker-fired and pulverized-coal-fired boilers. Test run on 520-hp. boiler fired by pulverized coal.

BOILER INSPECTION

Canada. Rules Governing the Inspection of Railway Stationary Boilers in Canada. Boiler Maker, vol. 21, no. 5, May 1921, pp. 137–138. Rules of Board of Railway Commissioners for Canada.

BOILER OPERATION

Losses. The Cost of Boiler Scale, W. F. Schaphorst. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 292, 1 fig. Chart for determining loss due to scale.

BOILERS

Electrically Heated. The Revel Electric Boiler (La chaudiere électrique revel). Industrie Electrique, vol. 30, no. 691, April 10, 1921, pp. 127–138, 3 figs. Pressure is automatically controlled by regulating surface of electrodes in contact with water.

The Utilization of Hydraulic Energy in the Electrification of Boilers (L'utilisation intégrale des forces hydrauliques par l'electrification des chaudières), P. Bergeon. Revue générale de l'Électricité, vol. 9, no. 17, April 23, 1921, pp. 561–567, 6 figs. Economical advantages of operating boilers by electricity.

Settings. Constructing Horizontal Boiler Settings, H. E. Dart. Boiler Maker, vol. 21, no. 5, May 1921, pp. 127–131, 5 figs. Typical setting designs adopted as standard by Hartford Steam Boiler Inspection and Insurance Co.

Single-Sheet. The Single-Sheet Lap-Seam Boiler, J. P. Morrison. Power, vol. 53, no. 17, April 26, 1921, pp. 652–655, 8 figs. Weaknesses in reliability of single-sheet, lap-seam boiler are pointed out by reference to numerous explosions.

BOILERS, WATER TUBE

Stirling. Development of the Stirling Boiler. Power, vol. 53, no. 16, April 19, 1921, pp. 632–634, 7 figs. Recent modifications making for standardization of classes, greater accessibility, elimination of priming and improved setting.

Seven Recent Changes in the Stirling Boiler Coal Age, vol. 19, no. 18, May 5, 1921, pp. 822–823, 3 figs. Front and rear steam drums raised, latter being protected by baffle. Steam now taken from rear drum. Superheater chamber enlarged. Bonding tile used front wall. Present standardization has reduced number of types from 14 to 3.

Tests. Boiler Tests with Pulverized Illinois Coal Henry Kreisinger and John Blizard. Mech. Eng., vol. 43, no. 5, May 1921, pp. 321–322 and 326, 2 figs. Tests of 468-hp. water-tube boiler fired with pulverized Illinois coal. Results showed that, contrary to customary specification, it is not necessary to pulverize coal to extreme fineness of 85 per cent through 200-mesh screen. Best results were obtained when coal was burned at rates from 0.5 lb. to 2 lb. per cu. ft. of combustion space per hour.

BORING HEADS

Modern Types. Modern Hollow Boring and Cutter Heads (Einige neuere Hohlbohr- und Messerköpfe), Valentin Litz. Werkstattstechnik, vol. 15, no. 7, Apr. 1, 1921, pp. 177–179, 32 figs. Details of various types used during and before war for boring out guns, shafts, rods, pipes, etc.

BORING MACHINES

Herbert. A New System of Precision Boring Eng. Production, vol. 2, no. 30, April 28, 1921, pp. 553–554, 2 figs. Boring machine manufactured by Alfred Herbert, Coventry, England, and designed for rapid machining of jigs and fixtures.

BRAKING

Heating of Wheel Tires. The Heating of Railway Wheels in Consequence of Braking (L'échauffement des bandages des roues de véhicules de chemins de fer par suite du freinage), R. Zehnder-Spörry. Bulletin technique de la Suisse romande, vol. 47, no. 9, April 30, 1921, pp. 97–102, 6 figs. Calculation of heat liberated by friction produced by braking.

BRAZING

See AIRCRAFT CONSTRUCTION MATERIALS, Brazing.

BROACHING

Keyways. Guide Bushings for Keyway Broaching. Machy. (Lond.), vol. 18, no. 447, April 21, 1921 pp. 75–76, 3 figs. Formulas for designing bushings for broaching accurate keyways.

Typical Operations. Broaching as a Production Factor, J. H. Moore. Can. Machy., vol. 25, no. 16, April 21, 1921, pp. 33–37, 10 figs. Typical broaching operations.

BRONZES

Tempering. Tempering of Tin Bronzes (Sur la trempe des laitons à l'étain) M. Léon Guillet. Comptes rendus des Séances de l'Académie des Sciences, vol. 172, no. 17, April 25, 1921, pp. 1038–1041, 2 figs. Effect of tempering on mechanical properties. Experiments on various types of tin bronzes.

BUILDING CONSTRUCTION

Concrete. Putting Up a Concrete Building Under Severe Difficulties, H. C. Paddock. Contract Rec., vol. 35, no. 16, April 20, 1921, pp. 383–385, 7 figs. Fish-freezing plant on island of St. Pierre erected on rocky site. Materials and labor imported Fire of extreme severity destroyed concrete and necessitated partial rebuilding.

C

CAR DUMPERS

Tilting Unloader. A Rapid Tilting Cradle Unloader for Box Cars. Ry. Age, vol. 70, no. 16, April 22, 1921, pp. 999–1000, 2 figs. Design developed by Ottumwa Box Car Loader Co., Iowa.

CAR WHEELS

Tire-Fixing Rolls. Tire Fixing Rolls for Railway Wheels. Engr., vol. 131, no. 3408, April 22, 1921, pp. 441, 3 figs. Hydraulic press manufactured by B. & S. Massey, Openshaw, Manchester.

CARBURETORS

Atmos. An Interesting Carburetter. Automobile Eng., vol. 11, no. 150, May 1921, pp. 178–179, 3 figs. Atmos carburetors. Throttle is only moving part and forms the center portion of the venturi tube. Situated at right angles to the main venturi is an auxiliary venturi, at throat of which jet is placed with its controlling needle.

German Oekonom. The "Oekonom" Carbureto (Der Kraftstoffvernebler "Oekonom"), Wa. Ostwald. Allgemeine Automobil-Zeitung, vol. 22, no. 7, Feb. 12, 1921, pp. 28–29, 3 figs. Consists of aluminum casing provided with two glass windows, from which condition of mixture can be observed, and no fuel can leave apparatus which is not thoroughly vaporized.

Jet Calibration. Calibrating Carbureter Jets in Quantity by Actual Flow Measurement, J. Edward Schipper. Automotive Industries, vol. 44, no. 18, May 5, 1921, pp. 958–959, 3 figs. Apparatus used by Zenith Carburetor Co. consists of tank with constant head, device for holding jet, electrically controlled timing elements, and graduates for measuring volume of flow in unit time. Each operator can test 160 jets per hour by use of one calibrating machine.

Research. Experimental Research on the Best Proportion of Fuel and Air for Explosive Motors (Recherches expérimentales sur les valeurs du titre, en essence, du mélange d'alimentation des moteurs a explosion), J. Boudet. Arts et Métiers, no. 3, Dec. 1920, pp. 49–54, 7 figs. Comparative study of various types of carburetors.

CARS

Steel. Progress in the Development of the All-Steel Car, J. J. Tatum, Ry. Rev., vol. 68, no. 19, May 7, 1921, pp. 699–700. Advisability of using copper bearing steel for improving performance from standpoint of service and maintenance. Paper read before Can. Ry. Club.

CARS, COAL

100-Ton. New Norfolk & Western 100-Ton Coal Cars, John A. Pilcher. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 293–298, 9 figs. Body supported on side bearings instead of center plate. New type six-wheel truck.

120-Ton. The 120-Ton Coal Cars of the Virginian Railroad. Ry. & Locomotive Eng., vol. 34, no. 5, May 1921, pp. 121–124, 5 figs. Cars carried on six-wheeled trucks.

CARS, FREIGHT

Draft-Gear Tests. Draft Gear Tests of the Railroad Administration. Ry. Mech. Engr., vol. 95, no. 5, May 1921, pp. 301–304, 1 fig. Results from gears after three years' service; destructive tests and rivet-shearing tests.

High-Capacity. Real Operating Economy in the use of High-Capacity Cars. Ry. Rev., vol. 68, no. 17, April 23, 1921, pp. 629–635, 9 figs. Net revenue tonnage of freight train increased 20 per cent where 100-ton cars are used on Norfolk & Western Ry.

Reinforced-Concrete. Reinforced-Concrete Freight Cars (Eisenbahnwagenkasten aus Eisenbeton), Max Gensbaur. Zeit. des Vereines deutscher Ingenieure, vol. 65, no. 17, Apr. 23, 1921, pp. 445–446, 3 figs. States that use of such cars is shown to be technically and economically feasible; reinforced-concrete ore cars with bottom discharge do not increase weight as compared with steel trucks; a special hardening of inside surface of concrete superstructure is not necessary.

Steel. Repairs or Maintenance of Steel Freight Cars, S. Lynn. Can. Ry. Club, vol. 20, no. 3, Mar. 8, 1921, pp. 24–32. Outline of practice, with notes on experience of Pittsburgh and Lake Erie Railroad.

CARS, REFRIGERATOR

Design. A System of Transit Refrigeration and Heating, Lewis Penwell. A.S.R.E. Jl., vol. 7, no. 2, Sept. 1920, pp. 140–150, 2 figs. Equipment for refrigerating railway cars.

CAST IRON

Research. The Co-Operation of Scientific and Industrial Research in the Iron Foundry—II, Thos. Vickers. Foundry Trade Jl., vol. 23, no. 242, April 7, 1921, pp. 316–319. Scope of British Cast Iron Research Assn. (Concluded.)

CASTINGS

Blowers. Rigging for Speed in Blower Work, Herbert R. Simonds. Foundry, vol. 49, no. 9, May 1, 1921, pp. 359–363, 8 figs. Castings for forced-draft blower manufactured by Coppus Eng. & Equipment Co., Worcester, Mass.

Cracks. Annular Cracks, R. R. Clarke. Metal Industry (N.Y.), vol. 19, no. 5, May 1921, pp. 193–194, 10 figs. Discussion of various theories accounting for their formation.

Grain. The Development of Grain and Its Importance for Foundry Practice (Der Gefügeaufbau und seine Bedeutung für den Giessereibetrieb), H. Czochralski. Giesserei-Zeitung, vol. 18, nos. 6 and 7, Mar. 15 and Apr. 1, 1921, pp. 85–90 and 103–109, 30 figs. Discusses rules governing growth of crystals, speed of crystallization, etc. Illustrations and photomicrographs of idiomorphic and xenomorphic crystals, dendritic crystal formations, etc.

Non-Ferrous. Non-Ferrous Castings in Spinning Molds, Louis J. Josten. Iron Age, vol. 107, no. 20, May 19, 1921, pp. 1289–1292, 4 figs. Casting of non-ferrous bands by centrifugal casting machine at works of George C. Clark Metal Products Co., Detroit.

CEMENT, PORTLAND

Specifications. Portland Cement, R. E. Stradling. Concrete, vol. 16, no. 4, April 1921, pp. 223–233, 10 figs. Comparison of British, American, French and German specifications and methods of testing. (Concluded.)

Testing. Judging the Quality of Portland Cement, R. J. Colony. Eng. World, vol. 18, no. 5, May 1921, pp. 331–334, 8 figs. Triangular concentration diagram constructed from results obtained in anal-

yses made in laboratory of Board of Water Supply of the City of New York. Paper read before Am. Inst. Min. and Metallurgical Engrs.

CENTRAL STATIONS

Power Zones. Economic Generation of Electricity by Power Zones, H. H. Kuhn. Elec. Rev., (Chicago) vol. 78, no. 18, April 30, 1921, pp. 683–687, 2 figs. Suggests scheme for concentration of electrical generating equipment at centers of naturally divided districts with facilities for fuel or water-power production and transmission at minimum cost. Chart for determining centralized service rates.

Superpower Zones. Legal and Financial Aspects of Superpower Plan. Elec. World, vol. 77, no. 21, May 21, 1921, pp. 1153–1156, 3 figs. Discussion at meeting of Superpower Survey in New York on May 13. Preliminary to completing report on proposed establishment of superpower zone in Northeastern United States.

CHAINS

Manufacture. The Manufacture of Driving Chains. Eng. Production, vol. 2, no. 32, May 12, 1921, pp. 603–610, 22 figs. Procedure at works of Hans Renold, England.

CHRONOMETERS

Developments. Latest Developments in Chronometry (Les derniers progrès de la chronomètrie), Léopold Reverchon. Nature (Paris), no. 2450, Mar. 19, 1921, pp. 177–181, 10 figs. Guillaume balancing wheel for marine chronometer.

CHUCKS

Magnetic. Magnetic Chucks—VI, Ellsworth Sheldon Am. Mach., vol. 54, nos. 18 and 19, May 5 and 12, 1921, pp. 787–789, 11 figs., and 819–823, 13 figs. Description of Heald multiple magnet chuck.

COAL

Analysis. The Analysis of Coal, S. Royllingworth. Colliery Guardian, vol. 121, no. 3146, April 15, 1921, pp. 1094–1095, 4 figs. Determination of proximate analysis of coal. From book by same writer soon to be published by Colliery Guardian Co.

Briquetting. Factors to be Borne in Mind in Making Briquets of Fine Materials, J. E. Stevens. Coal Age, vol. 19, no. 15, April 14, 1921, pp. 663–666, 5 figs. Methods of briquetting coal and peat.

Salvage. Concentrating Tables Turn Incombustible Sludge from Pond Into Good Fuel, William Strain. Coal Age, vol. 19, no. 17, April 28, 1921, pp. 741–743, 5 figs. Elevator and sluice broke up lumps of clay and coal enabling concentrating tables to remove two-thirds of ash. Installation of Renton Coal Co., Renton, Washington.

Sulphur in, Analysis. The Analysis of Sulphur Forms in Coal, Alfred R. Powell. U. S. Dept. of Interior, Bur. of Mines, technical paper 254, 1921, 21 pp., 1 fig. The applicability of method of Powell and Parr to various kinds of coal. Method was found to give correct and accurate results for analysis of sulphur forms in coal.

COAL BREAKERS

Design. Preparation Methods Susquehanna Has Built Into Reconstructed Pennsylvania Breaker. Coal Age, vol. 19, no. 14, April 7, 1921, pp. 618–622, 4 figs. Jigs are placed stepped down like stairway, using single chute for feed and another for discharge. "Rock" from jigs is screened and hand-picked for clean coal of size just washed, undersize going to condemned-coal conveyor for retreatment.

Single Roll Crusher is Well Safeguarded Against Breakage by Tramp Iron. Coal Age, vol. 19, no. 14, April 7, 1921, pp. 623–624, 3 figs. Four rods opposing helical springs hold frame together. For fine crushing reversible wearing strip is provided in lower portion of breaker. Shear pin made small enough to be safely constructed of mild steel.

COAL DUST

Hazards. Coal-Dust Hazards in Industrial Plants, L. D. Tracy. U. S. Dept. of Interior, Bur. of Mines, Reports of Investigations, no. 2243, 6 pp. 1 fig. Recommendations in regard to methods of handling pulverized coal with a view to preventing dust explosions.

COAL HANDLING

Mines. At Plumville Coal is Dumped in Mine and Carried by Apron Conveyor to Tipple, Donald J. Baker. Coal Age, vol. 19, no. 16, April 21, 1921, pp. 699–703, 9 figs. Refuse from picking table is conveyed to separate rock house. Generators supplying power to mines are driven by natural-gas engines which are found cheaper than steam-driven machines.

Piers. Export Coal Facilities at the Curtis Bay, Md., Terminals of the Baltimore & Ohio Railroad, P. G. Lang, Jr. Gen. Elec. Rev., vol. 24, no. 5, May 1921, pp. 433–435, 5 figs. Electrically operated coal trimmers installed at coal-loading pier.

Rotary Shovel. Rotary Shovel That Clears Wide Path but Delivers to Fixed Point of Discharge, S. H. Hunt. Coal Age, vol. 19, no. 18, May 5, 1921, pp. 789–791, 5 figs. Loading machines developed by Milwaukee Coke & Gas Co. Rotary motion is utilized in delivering material to mine car.

COAL WASHING

Methods. Method of Washing Coal for Metallurgical Coke at Risco, in Birmingham Field, E. P. Stewart. Coal Age, vol. 19, no. 18, May 5, 1921, pp. 807–810, 5 figs. Coal crushed to 1 in. and under, jigged and delivered at steel plant with only 6 per cent moisture without use of drainage tanks or centrifugal driers. Water clarified for reuse contains only 0.15 per cent solids.

Washing Coal With Air Instead of With Water, L. E. Woods. Coal Age, vol. 19, no. 18, May 5, 1921, pp. 810–812, 4 figs. Air forced upward through table deck and its load of material almost immediately, separates light from heavy particles. Machine has large capacity and product is dry.

COKE

Nomenclature. Report of Committee D-6 on Coke. Am. Soc. for Testing Matls., advance paper, 4 pp. Proposed tentative definitions of terms related to coke.

COKE HANDLING

Plants. Coke Handling System at Lawrence, Mass., H. B. Mosley. Am. Gas Jl., vol. 114, no. 20, May 14, 1921, pp. 421–422 and 433, 6 figs. Plants for handling, sizing and storing coke.

COKE OVENS

By-Product. By-product Coke Plant of the Jones & Laughlin Steel Co., C. R. Meissner. Chem. & Metallurgical Eng., vol. 24, no. 20, May 18, 1921, pp. 891–894, 7 figs. Description of installation and operation of standard Koppers coke-oven plant at Hazelwood, Pa., capable of coking under normal conditions 5000 tons of coal per day.

COMBUSTION

Composition of Gases. Theoretical Considerations on the Composition of Combustion Gases and Gasification of Carbon (Considérations theoriques au sujet de la composition des gaz de combustion et gazéification du carbone), M. J. Seigle. Revue de Métallurgie, vol. 18, no. 2, Feb. 1921, pp. 81–91, 3 figs. Equations establishing proportions of elementary constituents in gases from boilers, blast furnaces, etc.

Control. The Scientific Control of Combustion, H. T. Ringrose. Engineering, vol. 111, no. 2888, May 6, 1921, pp. 565–566, 4 figs. CO_2 recorder consisting of porous pot inside which is placed paper cartridge containing granules of soda lime. Unit is placed inside testing box into which can be put varying quantities of carbon dioxide from gas cylinder, and tube is coupled up in connection with inside of pot to manometer. Vacuum produced is registered by manometer.

COMPRESSED AIR

Explosions in Lines. Explosions in Compressed-Air Lines, E. D. Gardner. Iron Age, vol. 107, no. 20, May 19, 1921, pp. 1293–1294. Rupture of pipe in Arizona copper mine. Explosions sometimes due to carbonized cylinder oils. Cylinder temperature large factor.

Losses in Pipes. Pressure Losses in Compressed Air Piping. Compressed Air Mag., vol. 26, no. 5, May 1921, pp. 10092. Comparative study with genuine and substitute packing materials made in German coal mine.

Mines. The Production and Transmission of Compressed Air in Mines, John T. Pringle. Trans. of North of England Inst. of Min. & Mech. Engrs., vol. 71, part 2, Feb. 1921, pp. 24–39 and (discussion) pp. 39–42, 9 figs. Also in Trans.Inst.Min.Engrs., vol. 60, pt. 2, Jan. 1921, pp. 146–151 and (discussion) 151–164, 9 figs. Requirements of compressors. Performance of Ingersoll type.

Pneumatic Tubes. Pneumatic Transmission of Messages on Warships. Engineering, vol. 111, no. 2888, May 6, 1921, pp. 548–549, 10 figs. Apparatus for pneumatic transmission of messages, constructed by T. Cooke & Sons, York, England.

CONCRETE

Alkali Action on. Engineering Investigations, E. C. Bebb. U. S. Dept. of Int. Reclamation Rec., vol. 12, no. 5, May 1921, pp. 224–227, 3 figs. Progress in investigation of alkali action on concrete.

The Effect of Alkali Upon Concrete, S. H. McCrory. Public Works, vol. 50, no. 19, May 7, 1921, pp. 390–392, 1 fig. No method known of preventing such deterioration, but impermeability retards it.

Developments. Recent Developments in Concrete. Monthly Bul. Can. Inst. Min. & Metallurgy, no 109, May 1921, pp. 410–437, 16 figs. Survey of recent researches at representative institutions.

Proportioning Aggregates. A Logical Scheme for Determining the Concrete Making Value of Available Aggregates and Its Practical Application to the Production of Concrete of Pre-Determined Quality in the Field, G. M. Williams. Jl. Eng. Inst. of Canada, vol. 4, no. 5, May 1921, pp. 301–308, 6 figs. Investigation of current theories of proportioning concrete, and account of field tests.

CONCRETE, REINFORCED

Austrian Regulations. New Regulations for Reinforced Concrete in Austria (Neue Eisenbetonvorschriften in Oesterreich), Karl Haberkalt. Schweizerische Bauzeitung, vol. 77, nos. 13 and 14, Mar. 26 and Apr. 2, 1921, pp. 145–146 and 157–159, 2 figs. Includes table with new regulations giving permissible concrete stresses in kg. per sq. cm. Change from former regulations issued in 1911 by Bureau of Public Buildings was made in view of the shortage of building material due to changed conditions brought about by the war.

CONNECTING RODS

Manufacture. Making Motor-Car Engine Connecting Rods. Machy. (Lond.), vol. 18, no. 447, April 21, 1921, pp. 65–69, 11 figs. Machines and fixtures used for drilling, boring, milling, grinding, reaming and gaging operations.

CONVEYORS

Overhead. Overhead Conveyor System Solves Conveying Problem, F. N. Marcellus. Can. Manufacturer, vol. 41, no. 5, May 1921, pp. 45–47, 4 figs. System at works of London Machy. Co., Guelph, Canada.

Progressive Assembly. Progressive Assembly Conveyors, C. W. Starker. Machy. (N. Y.), vol. 27, no. 9, May 1921, pp. 831–832. Advantages of system in which products being assembled are conveyed past assembler.

COOLING TOWERS

Types. Water Cooling Towers—II, L. V. Robinson. Beama, vol. 8, no. 4, April 1921, pp. 346–353, 4 figs. Comparative study of different types.

COPPER

Separation from Nickel. The Separation of Copper from Nickel (Trennung des Kupfers von Nickel). Elektrochemische Zeit., vol. 27, no. 7, Jan. 1921, pp. 61–63. Process devised by Hybinette (Christiania) according to which an anode containing alloy of copper and nickel is electrolyzed in a solution of nickel sulphate and a weak acid.

COPPER ALLOYS

Copper-Zinc. The Specific Heat of Copper-Zinc Alloys at High Temperatures (Ueber die spezifische Wärme technischer Cu-Zn-Liegierungen bei höheren Temperaturen), Fr. Doerinckel and Max Werner. Zeit. für anorganische u. allgemeine Chemie, vol. 115, no. 1–2, Jan. 14, 1921, pp. 1–48, 16 figs. Specific heat of technically important copper-zinc alloys was determined according to mixture method.

Heat Treatment. Heat Treatment of Copper Alloys, J. S. Glen Primrose. Metal Industry (Lond.), vol. 18, no. 15, April 15, 1921, pp. 281–286, 6 figs. Effect of heat treatment upon finer properties. Paper read before Instn. British Foundrymen.

COLD STORAGE

Plant Design. Antwerp's Government Cold Stores. Cold Storage, vol. 24, no. 277, April 21, 1921, pp. 97–99, 3 figs. Refrigeration is effected by mixed system of direct expansion through pipes suspended from ceiling and ventilation from two powerful air-circulating batteries.

CORK

Artificial. The Most Recent Processes for the Production of Artificial Cork (Die nuesten Verfahren zur Herstellung von kunstlichem Kork), S. Halen. Kunststoffe, vol. 10, no. 24, Dec. 11, 1920, pp. 219–220. Foreign and domestic patented processes.

COST ACCOUNTING

Machine-Tool Industry. Cost Accounting for the Machine Tool Builder. Am. Mach., vol. 54, no. 17, April 28, 1921, pp. 726–731, 1 fig. Report of Scovell, Wellington & Co. to National Machine Tool Builders' Assn.

Overhead. When Machines are Idle. Factory, vol. 26, no. 8, April 15, 1921, pp. 947–952, 2 figs. Consideration of overhead cost in dull periods. Opinions expressed by manufacturers and industrial engineers.

COSTS

Industrial. A Comparison of Pre-War and Post-War Production Costs in Engineering, R. J. A. Pearson. Engineering, vol. 111, no. 2887, April 29, 1921, pp. 537–540. Application of mathematical methods to investigate financial and industrial situations. Paper read before Royal Statistical Soc.

COUPLINGS

Flexible. The Flexible Couplings of the German General Electric Co. (Die AEG-Streifenkupplung), L. Hultzsch. Der praktische Maschinen-Konstrukteur, vol. 53, no. 51, Dec. 23, 1920, pp. 438–439, 4 figs. Patented flexible coupling employing leather belts and adapted to both constant and alternating direction of rotation.

COUPLINGS, CAR

Automatic. The Boonzaier Automatic Coupling. Model Engr. & Elecn., vol. 44, no. 1042, April 14, 1921, pp. 290–291, 2 figs. Combination hook and link secured by means of fork or bracket to existing drawgear. Action of coupling is performed by one coupling member overriding other on contact.

CRANES

Traveling. Designing Traveling Cranes with Regard for Safe Operation, Nicolaas Prakken Am. Mach., vol. 54, no. 18, May 5, 1921, pp. 761–765, 10 figs. Typical safety appliances.

CUPOLAS

Design. Design of Cupola and Accessory Areas, Y. A. Dyer. Iron Age, vol. 107, no. 20, May 19, 1921 pp. 1313–1314 and 1347–1348, 1 fig. Ratios of tuyère to cupola and blast-pipe area; bustle pipe to blast pipe and tuyère areas. Height related to economic conditions.

Slag, Formation. Slag in Cupolas (Die Schlacken im Kupolofen), H. Kalpers. Zeit. für die gesamte Giessereipraxis, vol. 42, no. 15, Apr. 9, 1921, pp. 201–202. Deals with conditions causing slag formation and possibilities of combating them.

Supplementary Oil Firing. Recent Tests with Oil Addition in the Firing of Cupolas (Neuere Versuche mit Oelzusatzfeuerung für Kuppelofenbetrieb), Karl K. Berthold Stahl u. Eisen, vol. 41, no 12, Mar. 24, 1921, pp. 393–399, 1 fig. Account of tests, carried out in view of the coke shortage in Austria. It was possible to reduce the coke charge to extent of 4 to 5 kg. with an oil consumption of 1 kg. for each 100 kg. of charged iron. The hourly melting capacity was increased 30 to 50 per cent, the temperatures of iron fulfilled the highest requirements, and the so greatly feared enrichment with sulphur was con-

siderably reduced. Address before Austrian section of Assn. German Engrs., Vienna.

CUTTING TOOLS

Cutting Speeds. Cutting Speeds for Steel and Cast-Iron. Belting, vol. 18, no. 4, April 1921, pp. 72. Tables showing cutting speeds.

Diamond. The Diamond as a Cutting Tool. Eng. Production, vol. 2, no. 29, April 21, 1921, pp. 521–523, 10 figs. Its application in production work.

D

DIE CASTING

Methods. Die-Casting Methods and Metals—II and III, M. H. Potter. Foundry, vol. 49, nos. 9 and 10, May 1 and 15, 1921, pp. 342–344, 2 figs., and 404–406, 4 figs. Data regarding various metals and alloys which may be die cast are given and comparison is made between results from casting in sand and in dies. Methods of placing inserts in die castings. Details of cleaning baths and electroplating process.

DIE SINKING

Machine for. New Design of Die-Sinking Machine. Machy. (N.Y.), vol. 27, no. 9, May 1921, pp. 843–844, 6 figs. Machine brought out by Billings & Spencer Co., Hartford, Conn. Some of features are wide range of work, adaptability both to low and high cutter speeds, and method of holding and clamping shanks of cutters.

DIES

Conical Parts. Dies for Producing A Conical Part Machy (Lond.), vol. 18, no. 447, April 21, 1921, pp. 78–81, 14 figs. Operations in manufacturing difficult shell.

DIESEL ENGINES

Fuel Injection. Devices for Injection of Fuel Oil with Use of Injection Air in Diesel Engines without Regulation of the Discharge Openings (Vorrichungen zum Einspritzen von Brennöl unter Ver wendung von Einblaseluft ohn Regelung der Ausspritz-Querschnitte), F. E. Bielefeld. Oel- u. Gasmascine, vol. 18, no. 3, Mar. 1921, pp. 37–39, 3 figs. Describes fuel-injection devices patented by author.

German Submarines. The German Submarine Diesel Engine, Holbrook C. Gibson. Jl. Soc. Automotive Engrs., vol. 8, no. 5, May 1921, pp. 410–415, 10 figs. Engines were in majority of cases of Maschinenfabrik-Ausburg Nürnburg, four-cycle reversible type.

Manufacture. The First True Diesel Made in Canada. Mar. Eng., vol. 11, no. 4, April 1921, pp. 17–20, 6 figs. Manufacturing processes at works of Dominion Steel Products Co.

Marine. The Sulzer Marine Diesel Engines. Practical Engr., vol. 63, no. 1782, April 21, 1921, pp. 244–247, 3 figs. Efficiency curves of two-cycle and four-cycle engines.

Standard. Standard Fuel-Oil Vertical Two-Stroke-Cycle Diesel Engine. Power, vol. 53, no. 17, April 26, 1921, pp. 656–658, 7 figs. Engine manufactured hy Standard Fuel Oil Engine Co., Bucyrus, Ohio, in sizes from 50 to 200 hp.

Standardized. Standardized Diesel Engines—III, H. R. Setz. Mar. Eng., vol. 26, no. 5, May 1921, pp. 391–392, 1 fig. Description of valve-in-head method of scavenging for two-cycle type engine.

DRILLS

Breast. The Manufacture of a Breast Drill. Machy. (Lond.), vol. 18, no. 448, April 28, 1921, pp. 97–101, 11 figs. Practice of J. W. Bradley Small Tools Co., Leicester, England, in production of breast drills of single and two-speed types.

DROP FORGINGS

Heat Treatment. The Heat Treatment of Drop Forgings, Leslie Aitchison. Forging & Heat Treating, vol. 7, no. 5, May 1921, pp. 255–264, 6 figs. Influence of alloying elements on hardening. Mechanical effects of heat treatment.

Steel Castings vs. Drop Forgings Replace Steel Castings, F. B. Fairbanks. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 214–215, 3 figs. Claims forgings provide product of superior strength, toughness and resistance to shock and wear at lower cost.

DUST

Precipitation. Laying the Dust With Fog, Donovan McClure. Sci. Am. Monthly, vol. 3, no. 5, May 1921, pp. 419–420, 6 figs. Device for producing mist artificially.

E

EDUCATION, INDUSTRIAL

Employees. Today's Labor Problems, Charles Piez. Factory, vol. 26, no. 9, May 1, 1921, pp. 1059–1061. Urges instructing employees on subjects of wages, output, employer's profits, sympathetic strikes, and other questions about which they now have false notions.

ELECTRIC DRIVE

Steel Mills. The Steel-Mill Frequency Problem, B. G. Lamme. Elec. World, vol. 77, no. 17, April 23, 1921, pp. 921–923, 1 fig. Six general methods are pointed out for economically using 60-cycle purchased energy in plant with 25-cycle equipment.

ELECTRIC FURNACES

Electrode Economizers. Economizer Reduces Heat Dissipation, Frank Hodson. Iron Trade Rev., vol. 68, no. 17, April 28, 1921, pp. 1180–1181, 2 figs. Type of cooling ring or electrode economizer manufactured by Elec. Furnace Construction Co., Phila. Discussion presented at meeting of Am. Electrochemical Soc.

Foundries. Acid vs. Basic Electric Furnace for the Foundry, F. W. Brooke. Chem. & Metallurgical Eng., vol. 24, no. 18, May 4, 1921, p. 794. Uses to which each type is best suited.

Indirect Arc. A New Indirect Arc Furnace. Metal Industry (N. Y.), vol. 19, no. 5, May 1921, pp. 191–192, 2 figs. Three-phase gyrating electric furnace built by Volta Mfg. Co., Ontario.

Induction-Vacuum. The Influence of Gases on Metals (Gassers indvirkning paa metaller), Sigurd Hiorth Teknisk Ukeblad, vol. 68, nos. 7 and 8 Feb. 18 and 25, 1921, pp. 77–79 and 85–89, 6 figs. It is claimed that electric induction furnaces are excellently adapted to melting and heat-treating in vacuum. Notes on capacity of metals in molten state to absorb gases and retain them after congealing. Review of former works and experiments and brief account of author's work with the induction-vacuum furnace; process is said to be simple and inexpensive.

Smothered-Arc. Electric Furnaces for Melting Non-Ferrous Metals. Chem. & Metallurgical Eng. vol. 24, no. 18, May 4, 1921, p. 793, 1 fig. Typ. recently brought out by Gen. Elec. Co.

Smothered Arc for Nonferrous Furnaces. Foundry, vol. 49, no. 9, May 1, 1921, pp. 363–364, 2 figs. Electric furnaces developed by Gen. Elec. Co.

Steel Manufacture. Electric Furnaces for Making Steel—III, Alfred Stansfield. Blast Furnace & Steel Plant, vol. 9, no. 5, May 1921, pp. 324–327, 3 figs. Classification of electric steel-making furnaces. General features and advantages of arc furnace and resistance furnace. Operating features of electric furnaces.

ELECTRIC LAMPS, ARC

New Type. A New Type of Arc Lamp (Eine neuartige Bogenlampe), Albert Bencke. Elektrotechnischer Anzeiger, vol. 38, no. 49–50, Mar. 30, 1921, pp. 289–290. Arc lamp invented by M. Gabaccini and accepted by French government for marine purposes.

ELECTRIC LOCOMOTIVES

Developments. Review of Recent Large Electric Locomotives, A. Laternser. Elecn. (Lond.), vol. 86, no. 2243, May 13, 1921, pp. 584–586, 6 figs. Comparative data of recent American and European electric locomotives. Translated from Schweizerische Bauzeitung.

Steam vs. Characteristics of the Electric Locomotive. Ry. Elec. Engr., vol. 12, no. 5, May 1921, pp. 195–200, 8 figs. Advantages of electric locomotive over steam locomotive. Paper read before Franklin Inst.

ELECTRIC PLANTS

Interconnection. Limitations of Interconnection. E. C. Stone Elec. World, vol. 77, no. 18, April 30, 1921, pp. 990–991. Rupturing capacity of oil switches under short-circuit conditions limits interconnection unless plants are well distributed.

Operation. Output of Nine Electric Systems in 1920. Exceeded 1,000,000,000 Kw.-Hr. Each. Elec. World, vol. 77, no. 17, April 23, 1921, pp. 924–927. Data on generated and purchased output of largest generating and distributing systems in U. S. and Canada during 1920.

ELECTRIC RAILWAYS

Braking, Regenerative. Operating Curves and Operating Safety of Different Methods of Regenerative Braking in Electric Railways (Ueber Betriebskurven und Betreibssicherheit verschiedener Verfahren der Nutsbremsung bei elektrischen Bahnen), W. Kummer. Schweizerische Bauzeitung, vol. 77, nos. 13 and 14, Mar. 26 and Apr. 2, 1921, pp. 139–142 and 151–155, 11 figs. Investigation of operating curves of motors with separate excitation, of d.c. motors with series excitation, and single-phase motors with series excitation. It is pointed out that operating safety is to a great extent dependent on the operating curves, and it is concluded that regenerative braking can only be regarded as actually safe on 3-phase current and single-phase a.c. railroads using the Oerlikon connection or the single-phase 3-phase current transformation.

ELECTRIC TRANSMISSION LINES

Design. Economical Design of a Transmission Line, Ryotaro Mitsuda. Researches of Electrotechnical Laboratory, no. 79, Sept. 1919, 212 pp., 137 figs. Equations for determining most economical voltage of transmission, size of conductors and spacing of towers.

High-Voltage. French Transmission Line for 100 Kv., M. A. Henriod. Elec. World, vol. 77, no. 18, April 30, 1921, pp. 982–985, 12 figs. Transmission of energy at 110,000 volts over 115 miles of mountains and wooded country.

220,000-Volt. 220,000-Volt Transmission Progress. John A. Koontz, Jl. Electricity & Western Industry, vol. 46, no. 10, May 15, 1921, pp. 477–479, 9 figs. Report of Engineering Sub-Committee to the Pacific Coast Division of National Electric Light Association. It is concluded from laboratory research that the most logical scheme for developing a 220,000-volt insulator "seems to be that of utilizing the present 10-in. unit. . . but providing means to properly take care of the voltage distribution throughout the string. . . when more than eight or nine units are used."

Wire Joints. Mechanical Resistance of Joints of Aerial Electric Transmission Lines (Essais de la résistance mécanique de joints de fils de lignes aériennes). Industrie Electrique, vol. 30, no. 691, April 10, 1921, pp. 125–127. Tests conducted by Administration of Swiss Telegraph.

ELECTRIC WELDING

Rails. Methods for the Electric Welding of Rails (Methoden der elektrischen Schienenschweissung), P. Max Grempe. Elektrotechnischer Anzeiger, vol. 38, nos. 36, 38 and 39, Mar. 5, 9 and 10, 1921, pp. 193–197, 211–213 and 215–217, 39 figs. Development and advantages of electric welding of rails.

ELECTRIC WELDING, ARC

Boiler Shells. The Electric Welding of a Corroded Boiler-Shell, A. Kenneth Dawson. Trans. of North of England Inst. of Min. & Mech. Engrs., vol. 71, part 1, Dec. 1920, pp. 8–12, 2 figs. Repairing corroded Lancashire boiler by use of portable electric-arc welding apparatus.

Kjellberg System. The Kjellberg Welding and Its Use in Ship Construction (Kjellbergsche Schweissung und deren Verwendung bei Schiffsneubauten), Oskar Kjellberg. Autogene Metallbearbeitung, vol. 13, nos. 23 and 24, Dec. 1 and 15, 1920, pp. 292–295 and 306–310, and vol. 14, nos. 1, 2, 4 and 5, Jan. 1, 15, Feb. 15 and Mar. 1, 1921, pp. 4–7, 27–30, 51–54 and 74–78, 35 figs. Description of author's arc welding system and report of investigations of work carried out with this process. Notes on recommendations for electrically welded pulls in the United States. Testimony of British Lloyd concerning welded ships and author's own opinion. Possibilities of repairs.

Heat Treatment of Welds. Effect of Heat Treatment on Nitride in Metal Arc Welds, James W. Owens, J. H. Ramage and J. A. Watts. Welding Engr., vol. 6, no. 4, April 1921, pp. 23–27, 16 figs. Experiments indicated that heat treatment to which deposited metal has been subjected determines form of nitride in metal, and that form in which nitride exists has very decided effect upon physical properties of metal. Paper read before Am. Welding Soc.

EMPLOYEES' REPRESENTATION

Shop Committee. Employe Representation in Management, R. L. Wilson. Textile World, vol. 49, no. 18, April 30, 1921, pp. 117–119. Shop committees organized by East Pittsburgh plant of Westinghouse Elec. & Mfg. Co.

ENGINEERING

Scholarship and Eminence in. Scholarship and Eminence in Engineering, Raymond Walter. Eng. Education, vol. 11, no. 8, April 1921, pp. 361–377. Study of scholastic training of group of eminent engineers conducted under auspices of Am. Assn. Collegiate Registrars showed "close correspondence between good scholarship in collegiate courses and professional eminence in engineering."

ENGINEERING SCHOOLS

Columbia School of Mines. The Columbia School of Mines Idea, George J. Young. Eng. & Min. Jl., vol. 111, no. 18, April 30, 1921, pp. 744–746. Six years' course established by Columbia University. First three years form basis of liberal education and last three are devoted to technical studies.

ENGINEERING SOCIETIES

Federated American Engineering Societies. The American Engineering Council, Dexter S. Kimball. Science, vol. 53, no. 1374, April 29, 1921, pp. 399–402. Purpose and aims of Federated American Engineering Societies. Address delivered before Engineers' Club of Phila.

Organization. On the Organization of an Engineering Society, Morris Llewellyn Cooke. Mech. Eng., vol. 43, no. 5, May 1921, pp. 323–325 and 356.

EXPLOSIVES

Liquid Oxygen. Liquid Oxygen Explosives. Engr., vol. 131, no. 3408, April 22, 1921, pp. 426–427. Survey of recent developments in Germany and U. S.

EXTRUSION OF METALS

Extruded and Drawn Brass Rods. Extruded and Drawn Bars (Gepresste und gezogene Stangen). Der praktische Maschinen-Konstrukteur, vol. 54, no. 17, Apr. 28, 1921, pp. 70–72, 8 figs. Details of production at the metal works of the German Genera Elec. Co.

EYEBOLTS

Strength. The Mechanical Qualities Required in Eyebolts: With Some Consideration of the Izod Test, in its Relation to the Question of Brittleness in Mild Steel, R. T. Rolfe. Jl. Instn. Mech. Engrs., no. 3, April 1921, pp. 177–189, 4 figs. partly on supp. plate. From consideration of results found in experimental investigation it is suggested that carbon content of steel should be 0.34 per cent, and Izod figure not less than 25 ft-lb.

F

FANS

Electric Drive. Motor Drive for Fans and Blowers, Gordon Fox. Power, vol. 53, no. 17, April 26, 1921, pp. 664–666, 4 figs. Rotary blowers and fans classified and described. Limitations, characteristics in operation and power requirements. Motors best adapted to different types and regulation to use for speed adjustment.

FATIGUE

Iron and Steel Works. Fatigue and Efficiency in Iron and Steel Works—VI, H M. Vernon. Eng. & Indus. Management, vol. 5 no. 16, April 21, 1921, pp. 461–462. Investigations carried out by British Indus. Fatigue Research Board.

FIRE HOSE

Specifications. Report of Committee D-11 on Rubber Products. Am. Soc. for Testing Matls.,

advance paper, 69 pp. 3 figs. Proposed tentative specifications for cotton rubber-lined fire hose for use by public fire departments.

FIRE PROTECTION

Smoke Shafts. Automatic Arrangement for the Opening of Smoke Shafts in Rooms Exposed to Fire. (Automatische Einrichtung zum Oeffnen von Abgaseschächten in feuergefährlichen Räumen), Max Becker. Feuerwehrtechnische Zeit., vol. 8, no. 23–24, Dec. 20, 1920, pp. 204–207, 3 figs. Manometric releasing device developed and patented by writer.

FLOW OF GASES

Meters. A Device for Measuring the Flow of Gases, Carle R. Hayward. Chem. & Metallurgical Eng., vol. 24, no. 18, May 4, 1921, pp. 780, 3 figs. Apparatus developed in metallurgical laboratory of Mass. Inst. of Technology.

Pipes. Flow of Gas Calculation Chart, E. T. Anderson. Gas Age, vol. 47, no. 8, April 25, 1921, p. 322, 1 fig. Chart for calculating flow of gas in pipe.

FLYING BOATS

Caproni. The Caproni Tandem Triplane. Aeronautics, vol. 20, no. 393, April 28, 1921, p. 299, 6 figs. Characteristics: Engines, 8 liberty 400 hp.; span, 100 ft.; length, 74 ft.; height, 31 ft. 6 in.; chord, 8 ft. 7 in.; gap, 8 ft. 7 in.; wing area, 7800 sq. ft.; weight empty, 30,000 lb.; speed at ground, 90 m.p.h.

The Caproni "Nineplandem" Flying Boat. Flight vol. 13, no. 17, April 28, 1921, pp. 289–291, 9 figs. Characteristics: Span, 98 ft. 6 in.; length overall, 79 ft.; chord, 9 ft. 4 in.; total wing area, 7680 sq. ft.; total weight empty, 32,800 lb.; cruising speed, 87 m.p.h.

FORGING

Drop Hammers. Air vs. Steam for Forge Shop Hammers, Chas. R. Edwards. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 220–221 and 229, 4 figs Compressed air gives better expansion, no hot water drip, no delay in starting. Compressed air fittings must be tighter because of lower temperature. Costs about same in each case.

Cost of Operating Hammers With Air or Steam, G. H. Richey. Forging & Heat Treating, vol. 7, no. 4, April 1921, pp. 217–218. Calculations for ascertaining cost of operating hammers with compressed air and steam. Advantages of operating with air.

Spring Hammer. A New Forging Hammer (Ein neuer Bügelfeder-Hammer). Der praktische Maschinen-Konstrukteur, vol. 54, no. 14, Apr. 7, 1921, pp. 57–58, 3 figs. Describes new hammer built by Paul Rädeke, Berlin, mounted on four columns, main feature of which is the semi-circular laminated spring whose ends are attached to centrally located hammer face through links.
